$$\begin{aligned} w_{\text{comp, in}} &= \frac{kRT_1}{k-1} \left\{ \left( P_2/P_1 \right)^{(k-1)/k} - 1 \right\} \\ &= \frac{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})}{1.4-1} \left\{ (1000/100)^{0.4/1.4} - 1 \right\} \\ &= \mathbf{280.5 \text{ kJ/kg}} \end{aligned}$$

(b) The exergy of air at the compressor exit is simply the flow exergy at the exit state,

$$\begin{aligned} \psi_2 &= h_2 - h_0 - T_0(s_2 - s_0) + \frac{V_2^2}{2} + gz_2 \quad (\text{since the process } 0-2 \text{ is isentropic}) \\ &= c_p(T_2 - T_0) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(579.2 - 300) \text{ K} = \mathbf{280.6 \text{ kJ/kg}} \end{aligned}$$

which is the same as the compressor work input. This is not surprising since the compression process is reversible.

(c) The exergy of compressed air at 1 MPa after it is cooled to 300 K is again the flow exergy at that state,

$$\begin{aligned} \psi_3 &= h_3 - h_0 - T_0(s_3 - s_0) + \frac{V_3^2}{2} + gz_3 \\ &= c_p(T_3 - T_0) - T_0(s_3 - s_0) \quad (\text{since } T_3 = T_0 = 300 \text{ K}) \\ &= -T_0(s_3 - s_0) \end{aligned}$$

where

$$s_3 - s_0 = c_p \ln \frac{T_3}{T_0} - R \ln \frac{P_3}{P_0} = -R \ln \frac{P_3}{P_0} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{1000 \text{ kPa}}{100 \text{ kPa}} = -0.661 \text{ kJ/kg}\cdot\text{K}$$

Substituting,

$$\psi_3 = -(300 \text{ K})(-0.661 \text{ kJ/kg}\cdot\text{K}) = \mathbf{198 \text{ kJ/kg}}$$

Note that the exergy of compressed air decreases from 280.6 to 198 as it is cooled to ambient temperature.

**8-90** Air is preheated by hot exhaust gases in a cross-flow heat exchanger. The rate of heat transfer and the rate of exergy destruction in the heat exchanger are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. 3 Changes in the kinetic and potential energies of fluid streams are negligible. 4 Fluid properties are constant.

**Properties** The specific heats of air and combustion gases are given to be 1.005 and 1.10 kJ/kg.°C, respectively. The gas constant of air is  $R = 0.287$  kJ/kg.K (Table A-1).

**Analysis** We take the exhaust pipes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\approx 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 = \dot{Q}_{\text{out}} + \dot{m}h_2 \quad (\text{since } \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

$$\dot{Q}_{\text{out}} = \dot{m}C_p(T_1 - T_2)$$

Then the rate of heat transfer from the exhaust gases becomes

$$\dot{Q} = [\dot{m}C_p(T_{\text{in}} - T_{\text{out}})]_{\text{gas.}} = (1.1 \text{ kg/s})(1.1 \text{ kJ/kg.°C})(180^\circ\text{C} - 95^\circ\text{C}) = \mathbf{102.85 \text{ kW}}$$

The mass flow rate of air is

$$\dot{m} = \frac{P\dot{V}}{RT} = \frac{(95 \text{ kPa})(0.8 \text{ m}^3/\text{s})}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}) \times 293 \text{ K}} = 0.904 \text{ kg/s}$$

Noting that heat loss by exhaust gases is equal to the heat gain by the air, the air exit temperature becomes

$$\dot{Q} = [\dot{m}C_p(T_{\text{out}} - T_{\text{in}})]_{\text{air}} \rightarrow T_{\text{out}} = T_{\text{in}} + \frac{\dot{Q}}{\dot{m}C_p} = 20^\circ\text{C} + \frac{102.85 \text{ kW}}{(0.904 \text{ kg/s})(1.005 \text{ kJ/kg.°C})} = 133.2^\circ\text{C}$$

The rate of entropy generation within the heat exchanger is determined by applying the rate form of the entropy balance on the entire heat exchanger:

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \stackrel{\approx 0 \text{ (steady)}}{=}$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{\text{gen}} = 0 \quad (\text{since } \dot{Q} = 0)$$

$$\dot{m}_{\text{exhaust}} s_1 + \dot{m}_{\text{air}} s_3 - \dot{m}_{\text{exhaust}} s_2 - \dot{m}_{\text{air}} s_4 + \dot{S}_{\text{gen}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{m}_{\text{exhaust}}(s_2 - s_1) + \dot{m}_{\text{air}}(s_4 - s_3)$$

Noting that both fluid streams are liquids (incompressible substances), the rate of entropy generation is

$$\begin{aligned} \dot{S}_{\text{gen}} &= \dot{m}_{\text{exhaust}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{air}} c_p \ln \frac{T_4}{T_3} \\ &= (1.1 \text{ kg/s})(1.1 \text{ kJ/kg.K}) \ln \frac{95 + 273}{180 + 273} + (0.904 \text{ kg/s})(1.005 \text{ kJ/kg.K}) \ln \frac{133.2 + 273}{20 + 273} = 0.0453 \text{ kW/K} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (293 \text{ K})(0.0453 \text{ kW/K}) = \mathbf{13.3 \text{ kW}}$$

**8-91** Water is heated by hot oil in a heat exchanger. The outlet temperature of the oil and the rate of exergy destruction within the heat exchanger are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. 3 Changes in the kinetic and potential energies of fluid streams are negligible. 4 Fluid properties are constant.

**Properties** The specific heats of water and oil are given to be 4.18 and 2.3 kJ/kg·°C, respectively.

**Analysis** We take the cold water tubes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \overset{\text{0 (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta \text{ke} \approx \Delta \text{pe} \approx 0)$$

$$\dot{Q}_{\text{in}} = \dot{m}c_p(T_2 - T_1)$$

Then the rate of heat transfer to the cold water in this heat exchanger becomes

$$\dot{Q} = [\dot{m}c_p(T_{\text{out}} - T_{\text{in}})]_{\text{water}} = (4.5 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(70^\circ\text{C} - 20^\circ\text{C}) = 940.5 \text{ kW}$$

Noting that heat gain by the water is equal to the heat loss by the oil, the outlet temperature of the hot water is determined from

$$\dot{Q} = [\dot{m}c_p(T_{\text{in}} - T_{\text{out}})]_{\text{oil}} \rightarrow T_{\text{out}} = T_{\text{in}} - \frac{\dot{Q}}{\dot{m}c_p} = 170^\circ\text{C} - \frac{940.5 \text{ kW}}{(10 \text{ kg/s})(2.3 \text{ kJ/kg} \cdot ^\circ\text{C})} = 129.1^\circ\text{C}$$

(b) The rate of entropy generation within the heat exchanger is determined by applying the rate form of the entropy balance on the entire heat exchanger:

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \overset{\text{0 (steady)}}{=}$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{\text{gen}} = 0 \quad (\text{since } \dot{Q} = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{oil}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{oil}} s_4 + \dot{S}_{\text{gen}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{oil}}(s_4 - s_3)$$

Noting that both fluid streams are liquids (incompressible substances), the rate of entropy generation is determined to be

$$\begin{aligned} \dot{S}_{\text{gen}} &= \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{oil}} c_p \ln \frac{T_4}{T_3} \\ &= (4.5 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{70 + 273}{20 + 273} + (10 \text{ kg/s})(2.3 \text{ kJ/kg} \cdot \text{K}) \ln \frac{129.1 + 273}{170 + 273} = 0.736 \text{ kW/K} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(0.736 \text{ kW/K}) = 219 \text{ kW}$$

**8-92E** Steam is condensed by cooling water in a condenser. The rate of heat transfer and the rate of exergy destruction within the heat exchanger are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. 3 Changes in the kinetic and potential energies of fluid streams are negligible. 4 Fluid properties are constant. 5 The temperature of the environment is 77°F.

**Properties** The specific heat of water is 1.0 Btu/lbm·°F (Table A-3E). The enthalpy and entropy of vaporization of water at 120°F are 1025.2 Btu/lbm and  $s_{fg} = 1.7686$  Btu/lbm·R (Table A-4E).

**Analysis** We take the tube-side of the heat exchanger where cold water is flowing as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{in} - \dot{E}_{out}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{system}^{\text{0 (steady)}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta ke \cong \Delta pe \cong 0)$$

$$\dot{Q}_{in} = \dot{m}c_p(T_2 - T_1)$$

Then the rate of heat transfer to the cold water in this heat exchanger becomes

$$\begin{aligned} \dot{Q} &= [\dot{m}c_p(T_{out} - T_{in})]_{\text{water}} \\ &= (115.3 \text{ lbm/s})(1.0 \text{ Btu/lbm} \cdot \text{°F})(73\text{°F} - 60\text{°F}) = \mathbf{1499 \text{ Btu/s}} \end{aligned}$$

Noting that heat gain by the water is equal to the heat loss by the condensing steam, the rate of condensation of the steam in the heat exchanger is determined from

$$\dot{Q} = (\dot{m}h_{fg})_{\text{steam}} \longrightarrow \dot{m}_{\text{steam}} = \frac{\dot{Q}}{h_{fg}} = \frac{1499 \text{ Btu/s}}{1025.2 \text{ Btu/lbm}} = 1.462 \text{ lbm/s}$$

(b) The rate of entropy generation within the heat exchanger is determined by applying the rate form of the entropy balance on the entire heat exchanger:

$$\underbrace{\dot{S}_{in} - \dot{S}_{out}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{gen}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{system}^{\text{0 (steady)}}}_{\text{Rate of change of entropy}}$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{gen} = 0 \quad (\text{since } \dot{Q} = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{steam}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{steam}} s_4 + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{steam}}(s_4 - s_3)$$

Noting that water is an incompressible substance and steam changes from saturated vapor to saturated liquid, the rate of entropy generation is determined to be

$$\begin{aligned} \dot{S}_{gen} &= \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{steam}}(s_f - s_g) = \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} - \dot{m}_{\text{steam}} s_{fg} \\ &= (115.3 \text{ lbm/s})(1.0 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{73 + 460}{60 + 460} - (1.462 \text{ lbm/s})(1.7686 \text{ Btu/lbm} \cdot \text{R}) = 0.2613 \text{ Btu/s} \cdot \text{R} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 \dot{S}_{gen}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{gen} = (537 \text{ R})(0.2613 \text{ Btu/s} \cdot \text{R}) = \mathbf{140.3 \text{ Btu/s}}$$

**8-93** Steam expands in a turbine, which is not insulated. The reversible power, the exergy destroyed, the second-law efficiency, and the possible increase in the turbine power if the turbine is well insulated are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Potential energy change is negligible.

**Analysis** (a) The properties of the steam at the inlet and exit of the turbine are (Tables A-4 through A-6)

$$\begin{aligned} P_1 = 12 \text{ MPa} \quad \left. \begin{aligned} h_1 &= 3481.7 \text{ kJ/kg} \\ T_1 = 550^\circ\text{C} \end{aligned} \right\} s_1 &= 6.6554 \text{ kJ/kg}\cdot\text{K} \\ P_2 = 20 \text{ kPa} \quad \left. \begin{aligned} h_2 &= 2491.1 \text{ kJ/kg} \\ x_2 = 0.95 \end{aligned} \right\} s_2 &= 7.5535 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

The enthalpy at the dead state is

$$\begin{aligned} T_0 = 25^\circ\text{C} \quad \left. \begin{aligned} x &= 0 \end{aligned} \right\} h_0 &= 104.83 \text{ kJ/kg} \end{aligned}$$

The mass flow rate of steam may be determined from an energy balance on the turbine

$$\begin{aligned} \dot{m} \left( h_1 + \frac{V_1^2}{2} \right) &= \dot{m} \left( h_2 + \frac{V_2^2}{2} \right) + \dot{Q}_{\text{out}} + \dot{W}_a \\ \dot{m} \left[ 3481.7 \text{ kJ/kg} + \frac{(60 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right] &= \dot{m} \left[ 2491.1 \text{ kJ/kg} + \frac{(130 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right] \\ + 150 \text{ kW} + 2500 \text{ kW} &\longrightarrow \dot{m} = 2.693 \text{ kg/s} \end{aligned}$$

The reversible power may be determined from

$$\begin{aligned} \dot{W}_{\text{rev}} &= \dot{m} \left[ h_1 - h_2 - T_0(s_1 - s_2) + \frac{V_1^2 - V_2^2}{2} \right] \\ &= (2.693) \left[ (3481.7 - 2491.1) - (298)(6.6554 - 7.5535) + \frac{(60 \text{ m/s})^2 - (130 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right] \\ &= \mathbf{3371 \text{ kW}} \end{aligned}$$

(b) The exergy destroyed in the turbine is

$$\dot{X}_{\text{dest}} = \dot{W}_{\text{rev}} - \dot{W}_a = 3371 - 2500 = \mathbf{871 \text{ kW}}$$

(c) The second-law efficiency is

$$\eta_{II} = \frac{\dot{W}_a}{\dot{W}_{\text{rev}}} = \frac{2500 \text{ kW}}{3371 \text{ kW}} = \mathbf{0.742}$$

(d) The energy of the steam at the turbine inlet in the given dead state is

$$\dot{Q} = \dot{m}(h_1 - h_0) = (2.693 \text{ kg/s})(3481.7 - 104.83) \text{ kJ/kg} = 9095 \text{ kW}$$

The fraction of energy at the turbine inlet that is converted to power is

$$f = \frac{\dot{W}_a}{\dot{Q}} = \frac{2500 \text{ kW}}{9095 \text{ kW}} = 0.2749$$

Assuming that the same fraction of heat loss from the turbine could have been converted to work, the possible increase in the power if the turbine is to be well-insulated becomes

$$\dot{W}_{\text{increase}} = f\dot{Q}_{\text{out}} = (0.2749)(150 \text{ kW}) = \mathbf{41.2 \text{ kW}}$$

**8-94** Air is compressed in a compressor that is intentionally cooled. The actual and reversible power inputs, the second law efficiency, and the mass flow rate of cooling water are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and the specific heat of air at room is  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ . the specific heat of water at room temperature is  $c_w = 4.18 \text{ kJ/kg}\cdot\text{K}$  (Tables A-2, A-3).

**Analysis** (a) The mass flow rate of air is

$$\dot{m} = \rho \dot{V}_1 = \frac{P_1}{RT_1} \dot{V}_1 = \frac{(100 \text{ kPa})}{(0.287 \text{ kJ/kg}\cdot\text{K})(20 + 273 \text{ K})} (4.5 \text{ m}^3/\text{s}) = 5.351 \text{ kg/s}$$

The power input for a reversible-isothermal process is given by

$$\dot{W}_{\text{rev}} = \dot{m} R T_1 \ln \frac{P_2}{P_1} = (5.351 \text{ kg/s})(0.287 \text{ kJ/kg}\cdot\text{K})(20 + 273 \text{ K}) \ln \left( \frac{900 \text{ kPa}}{100 \text{ kPa}} \right) = \mathbf{988.8 \text{ kW}}$$

Given the isothermal efficiency, the actual power may be determined from

$$\dot{W}_{\text{actual}} = \frac{\dot{W}_{\text{rev}}}{\eta_T} = \frac{988.8 \text{ kW}}{0.70} = \mathbf{1413 \text{ kW}}$$

(b) The given isothermal efficiency is actually the second-law efficiency of the compressor

$$\eta_{\text{II}} = \eta_T = \mathbf{0.70}$$

(c) An energy balance on the compressor gives

$$\begin{aligned} \dot{Q}_{\text{out}} &= \dot{m} \left[ C_p (T_1 - T_2) + \frac{V_1^2 - V_2^2}{2} \right] + \dot{W}_{\text{actual, in}} \\ &= (5.351 \text{ kg/s}) \left[ (1.005 \text{ kJ/kg}\cdot^\circ\text{C})(20 - 60)^\circ\text{C} + \frac{0 - (80 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right] + 1413 \text{ kW} \\ &= \mathbf{1181 \text{ kW}} \end{aligned}$$

The mass flow rate of the cooling water is

$$\dot{m}_w = \frac{\dot{Q}_{\text{out}}}{c_w \Delta T} = \frac{1181 \text{ kW}}{(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(10^\circ\text{C})} = \mathbf{28.25 \text{ kg/s}}$$

**8-95** Water is heated in a chamber by mixing it with saturated steam. The temperature of the steam entering the chamber, the exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Heat loss from the chamber is negligible.

**Analysis** (a) The properties of water are (Tables A-4 through A-6)

$$\begin{aligned} T_1 = 15^\circ\text{C} \quad & \left\{ \begin{array}{l} h_1 = h_0 = 62.98 \text{ kJ/kg} \\ x_1 = 0 \end{array} \right. \quad \left\{ \begin{array}{l} s_1 = s_0 = 0.22447 \text{ kJ/kg}\cdot\text{K} \end{array} \right. \\ T_3 = 45^\circ\text{C} \quad & \left\{ \begin{array}{l} h_3 = 188.44 \text{ kJ/kg} \\ x_1 = 0 \end{array} \right. \quad \left\{ \begin{array}{l} s_3 = 0.63862 \text{ kJ/kg}\cdot\text{K} \end{array} \right. \end{aligned}$$

An energy balance on the chamber gives

$$\begin{aligned} \dot{m}_1 h_1 + \dot{m}_2 h_2 &= \dot{m}_3 h_3 = (\dot{m}_1 + \dot{m}_2) h_3 \\ (4.6 \text{ kg/s})(62.98 \text{ kJ/kg}) + (0.23 \text{ kg/s}) h_2 &= (4.6 + 0.23 \text{ kg/s})(188.44 \text{ kJ/kg}) \\ h_2 &= 2697.5 \text{ kJ/kg} \end{aligned}$$

The remaining properties of the saturated steam are

$$\begin{aligned} h_2 = 2697.5 \text{ kJ/kg} \quad & \left\{ \begin{array}{l} T_2 = \mathbf{114.3^\circ\text{C}} \\ x_2 = 1 \end{array} \right. \quad \left\{ \begin{array}{l} s_2 = 7.1907 \text{ kJ/kg}\cdot\text{K} \end{array} \right. \end{aligned}$$

(b) The specific exergy of each stream is

$$\begin{aligned} \psi_1 &= 0 \\ \psi_2 &= h_2 - h_0 - T_0(s_2 - s_0) \\ &= (2697.5 - 62.98) \text{ kJ/kg} - (15 + 273 \text{ K})(7.1907 - 0.22447) \text{ kJ/kg}\cdot\text{K} = 628.28 \text{ kJ/kg} \\ \psi_3 &= h_3 - h_0 - T_0(s_3 - s_0) \\ &= (188.44 - 62.98) \text{ kJ/kg} - (15 + 273 \text{ K})(0.63862 - 0.22447) \text{ kJ/kg}\cdot\text{K} = 6.18 \text{ kJ/kg} \end{aligned}$$

The exergy destruction is determined from an exergy balance on the chamber to be

$$\begin{aligned} \dot{X}_{\text{dest}} &= \dot{m}_1 \psi_1 + \dot{m}_2 \psi_2 - (\dot{m}_1 + \dot{m}_2) \psi_3 \\ &= 0 + (0.23 \text{ kg/s})(628.28 \text{ kJ/kg}) - (4.6 + 0.23 \text{ kg/s})(6.18 \text{ kJ/kg}) \\ &= \mathbf{114.7 \text{ kW}} \end{aligned}$$

(c) The second-law efficiency for this mixing process may be determined from

$$\eta_{\text{II}} = \frac{(\dot{m}_1 + \dot{m}_2) \psi_3}{\dot{m}_1 \psi_1 + \dot{m}_2 \psi_2} = \frac{(4.6 + 0.23 \text{ kg/s})(6.18 \text{ kJ/kg})}{0 + (0.23 \text{ kg/s})(628.28 \text{ kJ/kg})} = \mathbf{0.207}$$

## Review Problems

**8-96** Refrigerant-134a is expanded adiabatically in an expansion valve. The work potential of R-134a at the inlet, the exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The properties of the refrigerant at the inlet and exit of the valve and at dead state are (Tables A-11 through A-13)

$$\begin{aligned} P_1 = 1.2 \text{ MPa} & \left\{ \begin{aligned} h_1 &= 108.23 \text{ kJ/kg} \\ T_1 = 40^\circ\text{C} & \left\{ \begin{aligned} s_1 &= 0.39424 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \\ P_2 = 180 \text{ kPa} & \left\{ \begin{aligned} h_2 &= h_1 = 108.23 \text{ kJ/kg} \\ s_2 &= 0.42271 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \\ P_0 = 100 \text{ kPa} & \left\{ \begin{aligned} h_0 &= 272.17 \text{ kJ/kg} \\ T_0 = 20^\circ\text{C} & \left\{ \begin{aligned} s_0 &= 1.0918 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

The specific exergy of the refrigerant at the inlet and exit of the valve are

$$\begin{aligned} \psi_1 &= h_1 - h_0 - T_0(s_1 - s_0) \\ &= (108.23 - 272.17) \text{ kJ/kg} - (20 + 273.15 \text{ K})(0.39424 - 1.0918) \text{ kJ/kg}\cdot\text{K} = \mathbf{40.55 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} \psi_2 &= h_2 - h_0 - T_0(s_2 - s_0) \\ &= (108.23 - 272.17) \text{ kJ/kg} - (20 + 273.15 \text{ K})(0.42271 - 1.0918) \text{ kJ/kg}\cdot\text{K} = 32.20 \text{ kJ/kg} \end{aligned}$$

(b) The exergy destruction is determined to be

$$x_{\text{dest}} = T_0(s_2 - s_1) = (20 + 273.15 \text{ K})(0.42271 - 0.39424) \text{ kJ/kg}\cdot\text{K} = \mathbf{8.34 \text{ kJ/kg}}$$

(c) The second-law efficiency for this process may be determined from

$$\eta_{\text{II}} = \frac{\psi_2}{\psi_1} = \frac{32.20 \text{ kJ/kg}}{40.55 \text{ kJ/kg}} = \mathbf{0.794}$$

**8-97** Steam is accelerated in an adiabatic nozzle. The exit velocity, the rate of exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Potential energy changes are negligible.

**Analysis** (a) The properties of the steam at the inlet and exit of the turbine and at the dead state are (Tables A-4 through A-6)

$$\begin{aligned} P_1 = 3.5 \text{ MPa} & \left\{ \begin{aligned} h_1 &= 2978.4 \text{ kJ/kg} \\ T_1 = 300^\circ\text{C} & \left\{ \begin{aligned} s_1 &= 6.4484 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \\ P_2 = 1.6 \text{ kPa} & \left\{ \begin{aligned} h_2 &= 2919.9 \text{ kJ/kg} \\ T_2 = 250^\circ\text{C} & \left\{ \begin{aligned} s_2 &= 6.6753 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \\ T_0 = 18^\circ\text{C} & \left\{ \begin{aligned} h_0 &= 75.54 \text{ kJ/kg} \\ x = 0 & \left\{ \begin{aligned} s_0 &= 0.2678 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

The exit velocity is determined from an energy balance on the nozzle

$$\begin{aligned} h_1 + \frac{V_1^2}{2} &= h_2 + \frac{V_2^2}{2} \\ 2978.4 \text{ kJ/kg} + \frac{(0 \text{ m/s})^2}{2} &= 2919.9 \text{ kJ/kg} + \frac{V_2^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ V_2 &= \mathbf{342.0 \text{ m/s}} \end{aligned}$$

(b) The rate of exergy destruction is the exergy decrease of the steam in the nozzle

$$\begin{aligned} \dot{X}_{\text{dest}} &= \dot{m} \left[ h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} - T_0(s_2 - s_1) \right] \\ &= (0.4 \text{ kg/s}) \left[ (2919.9 - 2978.4) \text{ kJ/kg} + \frac{(342 \text{ m/s})^2 - 0}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right. \\ &\quad \left. - (291 \text{ K})(6.6753 - 6.4484) \text{ kJ/kg}\cdot\text{K} \right] \\ &= \mathbf{26.41 \text{ kW}} \end{aligned}$$

(c) The exergy of the refrigerant at the inlet is

$$\begin{aligned} \dot{X}_1 &= \dot{m} \left[ h_1 - h_0 + \frac{V_1^2}{2} - T_0(s_1 - s_0) \right] \\ &= (0.4 \text{ kg/s}) [(2978.4 - 75.54) \text{ kJ/kg} + 0 - (291 \text{ K})(6.4484 - 0.2678) \text{ kJ/kg}\cdot\text{K}] \\ &= 441.72 \text{ kW} \end{aligned}$$

The second-law efficiency for this device may be defined as the exergy output divided by the exergy input:

$$\eta_{\text{II}} = \frac{\dot{X}_2}{\dot{X}_1} = 1 - \frac{\dot{X}_{\text{dest}}}{\dot{X}_1} = 1 - \frac{26.41 \text{ kW}}{441.72 \text{ kW}} = \mathbf{0.940}$$

**8-98** R-134a is expanded in an adiabatic process with an isentropic efficiency of 0.85. The second law efficiency is to be determined.

**Assumptions** 1 Kinetic and potential energy changes are negligible. 2 The device is adiabatic and thus heat transfer is negligible.

**Analysis** We take the R-134a as the system. This is a closed system since no mass enters or leaves. The energy balance for this stationary closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$-W_{\text{out}} = \Delta U = m(u_2 - u_1)$$

From the R-134a tables (Tables A-11 through A-13),

$$\left. \begin{array}{l} P_1 = 1600 \text{ kPa} \\ T_1 = 80^\circ\text{C} \end{array} \right\} \begin{array}{l} v_1 = 0.014362 \text{ m}^3/\text{kg} \\ u_1 = 282.09 \text{ kJ/kg} \\ s_1 = 0.9875 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 100 \text{ kPa} \\ s_{2s} = s_1 \end{array} \right\} u_{2s} = 223.16 \text{ kJ/kg}$$

The actual work input is

$$w_{a,\text{out}} = \eta_T w_{s,\text{out}} = \eta_T (u_1 - u_{2s}) = (0.85)(282.09 - 223.16) \text{ kJ/kg} = 50.09 \text{ kJ/kg}$$

The actual internal energy at the end of the expansion process is

$$w_{a,\text{out}} = (u_1 - u_2) \longrightarrow u_2 = u_1 - w_{a,\text{out}} = 282.09 - 50.09 = 232.00 \text{ kJ/kg}$$

Other actual properties at the final state are (Table A-13)

$$\left. \begin{array}{l} P_2 = 100 \text{ kPa} \\ u_2 = 232.00 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} v_2 = 0.2139 \text{ m}^3/\text{lbm} \\ s_2 = 1.0251 \text{ kJ/kg} \cdot \text{K} \end{array}$$

The useful work is determined from

$$\begin{aligned} w_u &= w_{a,\text{out}} - w_{\text{surr}} = w_{a,\text{out}} - P_0(v_2 - v_1) \\ &= 50.09 \text{ kJ/kg} - (100 \text{ kPa})(0.2139 - 0.014362) \text{ m}^3/\text{kg} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 30.14 \text{ kJ/kg} \end{aligned}$$

The exergy change between initial and final states is

$$\begin{aligned} \phi_1 - \phi_2 &= u_1 - u_2 + P_0(v_1 - v_2) - T_0(s_1 - s_2) \\ &= (282.09 - 232.00) \text{ kJ/kg} + (100 \text{ kPa})(0.014362 - 0.2139) \text{ m}^3/\text{kg} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &\quad - (298 \text{ K})(0.9875 - 1.0251) \text{ kJ/kg} \cdot \text{K} \\ &= 41.34 \text{ kJ/kg} \end{aligned}$$

The second law efficiency is then

$$\eta_{\text{II}} = \frac{w_u}{\Delta \phi} = \frac{30.14 \text{ kJ/kg}}{41.34 \text{ kJ/kg}} = \mathbf{0.729}$$

**8-99** Steam is condensed in a closed system at a constant pressure from a saturated vapor to a saturated liquid by rejecting heat to a thermal energy reservoir. The second law efficiency is to be determined.

**Assumptions 1** Kinetic and potential energy changes are negligible.

**Analysis** We take the steam as the system. This is a closed system since no mass enters or leaves. The energy balance for this stationary closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$W_{b,\text{in}} - Q_{\text{out}} = \Delta U = m(u_2 - u_1)$$

From the steam tables (Table A-5),

$$\left. \begin{array}{l} P_1 = 40 \text{ kPa} \\ \text{Sat. vapor} \end{array} \right\} \begin{array}{l} \nu_1 = \nu_g = 3.9933 \text{ m}^3/\text{kg} \\ u_1 = u_g = 2476.3 \text{ kJ/kg} \\ s_1 = s_g = 7.6691 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 40 \text{ kPa} \\ \text{Sat. liquid} \end{array} \right\} \begin{array}{l} \nu_2 = \nu_f = 0.001026 \text{ m}^3/\text{kg} \\ u_2 = u_f = 317.58 \text{ kJ/kg} \\ s_2 = s_f = 1.0261 \text{ kJ/kg} \cdot \text{K} \end{array}$$

The boundary work during this process is

$$w_{b,\text{in}} = P(\nu_1 - \nu_2) = (40 \text{ kPa})(3.9933 - 0.001026) \text{ m}^3/\text{kg} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 159.7 \text{ kJ/kg}$$

The heat transfer is determined from the energy balance:

$$q_{\text{out}} = w_{b,\text{in}} - (u_2 - u_1) = 159.7 \text{ kJ/kg} - (317.58 - 2476.3) \text{ kJ/kg} = 2318.4 \text{ kJ/kg}$$

The exergy change between initial and final states is

$$\begin{aligned} \phi_1 - \phi_2 &= u_1 - u_2 + P_0(\nu_1 - \nu_2) - T_0(s_1 - s_2) - q_{\text{out}} \left( 1 - \frac{T_0}{T_R} \right) \\ &= (2476.3 - 317.58) \text{ kJ/kg} + (100 \text{ kPa})(3.9933 - 0.001026) \text{ m}^3/\text{kg} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &\quad - (298 \text{ K})(7.6691 - 1.0261) \text{ kJ/kg} \cdot \text{K} - (2318.4 \text{ kJ/kg}) \left( 1 - \frac{298 \text{ K}}{303 \text{ K}} \right) \\ &= 540.1 \text{ kJ/kg} \end{aligned}$$

The second law efficiency is then

$$\eta_{\text{II}} = \frac{w_{b,\text{in}}}{\Delta \phi} = \frac{159.7 \text{ kJ/kg}}{540.1 \text{ kJ/kg}} = \mathbf{0.296}$$

**8-100** R-134a is vaporized in a closed system at a constant pressure from a saturated liquid to a saturated vapor by transferring heat from a reservoir at two pressures. The pressure that is more effective from a second-law point of view is to be determined.

**Assumptions 1** Kinetic and potential energy changes are negligible.

**Analysis** We take the R-134a as the system. This is a closed system since no mass enters or leaves. The energy balance for this stationary closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$Q_{\text{in}} - W_{b,\text{out}} = \Delta U = m(u_2 - u_1)$$

$$Q_{\text{in}} = W_{b,\text{out}} + \Delta U$$

$$Q_{\text{in}} = \Delta H = m(h_2 - h_1)$$

**At 100 kPa:**

From the R-134a tables (Table A-12),

$$u_{fg} @ 100 \text{ kPa} = 197.98 \text{ kJ/kg}$$

$$h_{fg} @ 100 \text{ kPa} = 217.16 \text{ kJ/kg}$$

$$s_{fg} @ 100 \text{ kPa} = 0.87995 \text{ kJ/kg} \cdot \text{K}$$

$$\nu_{fg} @ 100 \text{ kPa} = \nu_g - \nu_f = 0.19254 - 0.0007259 = 0.19181 \text{ m}^3/\text{kg}$$

The boundary work during this process is

$$w_{b,\text{out}} = P(\nu_2 - \nu_1) = P\nu_{fg} = (100 \text{ kPa})(0.19181 \text{ m}^3/\text{kg}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 19.18 \text{ kJ/kg}$$

The useful work is determined from

$$w_u = w_{b,\text{out}} - w_{\text{surr}} = P(\nu_2 - \nu_1) - P_0(\nu_2 - \nu_1) = 0 \text{ kJ/kg}$$

since  $P = P_0 = 100 \text{ kPa}$ . The heat transfer from the energy balance is

$$q_{\text{in}} = h_{fg} = 217.16 \text{ kJ/kg}$$

The exergy change between initial and final states is

$$\begin{aligned} \phi_1 - \phi_2 &= u_1 - u_2 + P_0(\nu_1 - \nu_2) - T_0(s_1 - s_2) + q_{\text{in}} \left( 1 - \frac{T_0}{T_R} \right) \\ &= -u_{fg} - P_0\nu_{fg} + T_0s_{fg} + q_{\text{in}} \left( 1 - \frac{T_0}{T_R} \right) \\ &= -197.98 \text{ kJ/kg} - (100 \text{ kPa})(0.19181 \text{ m}^3/\text{kg}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) + (298 \text{ K})(0.87995 \text{ kJ/kg} \cdot \text{K}) \\ &\quad + (217.16 \text{ kJ/kg}) \left( 1 - \frac{298 \text{ K}}{273 \text{ K}} \right) \\ &= 25.18 \text{ kJ/kg} \end{aligned}$$

The second law efficiency is then

$$\eta_{\text{II}} = \frac{w_u}{\Delta \phi} = \frac{0 \text{ kJ/kg}}{25.18 \text{ kJ/kg}} = 0$$

**At 200 kPa:**

$$u_{fg @ 200 \text{ kPa}} = 186.21 \text{ kJ/kg}$$

$$h_{fg @ 200 \text{ kPa}} = 206.03 \text{ kJ/kg}$$

$$s_{fg @ 200 \text{ kPa}} = 0.78316 \text{ kJ/kg} \cdot \text{K}$$

$$\nu_{fg @ 200 \text{ kPa}} = \nu_g - \nu_f = 0.099867 - 0.0007533 = 0.099114 \text{ m}^3/\text{kg}$$

$$w_{b,\text{out}} = P(\nu_2 - \nu_1) = P\nu_{fg} = (200 \text{ kPa})(0.099114 \text{ m}^3/\text{kg}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 19.82 \text{ kJ/kg}$$

$$w_u = w_{b,\text{out}} - w_{\text{surr}} = P(\nu_2 - \nu_1) - P_0(\nu_2 - \nu_1)$$

$$= (P - P_0)\nu_{fg} = (200 - 100) \text{ kPa}(0.099114 \text{ m}^3/\text{kg}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 9.911 \text{ kJ/kg}$$

$$q_{\text{in}} = h_{fg} = 206.03 \text{ kJ/kg}$$

$$\phi_1 - \phi_2 = u_1 - u_2 + P_0(\nu_1 - \nu_2) - T_0(s_1 - s_2) + q_{\text{in}} \left( 1 - \frac{T_0}{T_R} \right)$$

$$= -u_{fg} - P_0\nu_{fg} + T_0s_{fg} + q_{\text{in}} \left( 1 - \frac{T_0}{T_R} \right)$$

$$= -186.21 \text{ kJ/kg} - (100 \text{ kPa})(0.099114 \text{ m}^3/\text{kg}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) + (298 \text{ K})(0.78316 \text{ kJ/kg} \cdot \text{K})$$

$$+ (206.03 \text{ kJ/kg}) \left( 1 - \frac{298 \text{ K}}{273 \text{ K}} \right)$$

$$= 18.39 \text{ kJ/kg}$$

$$\eta_{\text{II}} = \frac{w_u}{\Delta\phi} = \frac{9.911 \text{ kJ/kg}}{18.39 \text{ kJ/kg}} = \mathbf{0.539}$$

The process at 200 kPa is more effective from a work production standpoint.

**8-101E** Steam is expanded in a two-stage turbine. Six percent of the inlet steam is bled for feedwater heating. The isentropic efficiencies for the two stages of the turbine are given. The second-law efficiency of the turbine is to be determined.

**Assumptions 1** This is a steady-flow process since there is no change with time. **2** The turbine is well-insulated, and there is no heat transfer from the turbine.

**Analysis** There is one inlet and two exits. We take the turbine as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0$$

$$\begin{aligned}\dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{m}_1 h_1 &= \dot{m}_2 h_2 + \dot{m}_3 h_3 + \dot{W}_{\text{out}} \\ \dot{W}_{\text{out}} &= \dot{m}_1 h_1 - \dot{m}_2 h_2 - \dot{m}_3 h_3 \\ w_{\text{out}} &= h_1 - 0.06 h_2 - 0.94 h_3 \\ w_{\text{out}} &= (h_1 - h_2) + 0.94(h_2 - h_3)\end{aligned}$$

The isentropic and actual enthalpies at three states are determined using steam tables as follows:

$$\left. \begin{array}{l} P_1 = 500 \text{ psia} \\ T_1 = 600^\circ\text{F} \end{array} \right\} \begin{array}{l} h_1 = 1298.6 \text{ Btu/lbm} \\ s_1 = 1.5590 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_2 = 100 \text{ psia} \\ s_{2s} = s_1 = 1.5590 \text{ Btu/lbm} \cdot \text{R} \end{array} \right\} \begin{array}{l} x_{2s} = 0.9609 \\ h_{2s} = 1152.7 \text{ Btu/lbm} \end{array}$$

$$\eta_{T,1} = \frac{h_1 - h_2}{h_1 - h_{2s}} \longrightarrow h_2 = h_1 - \eta_{T,1}(h_1 - h_{2s}) = 1298.6 - (0.97)(1298.6 - 1152.7) = 1157.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 100 \text{ psia} \\ h_2 = 1157.1 \text{ Btu/lbm} \end{array} \right\} \begin{array}{l} x_2 = 0.9658 \\ s_2 = 1.5646 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_3 = 5 \text{ psia} \\ s_3 = s_2 = 1.5646 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} \begin{array}{l} x_{3s} = 0.8265 \\ h_{3s} = 957.09 \text{ Btu/lbm} \end{array}$$

$$\eta_{T,2} = \frac{h_2 - h_3}{h_2 - h_{3s}} \longrightarrow h_3 = h_2 - \eta_{T,2}(h_2 - h_{3s}) = 1157.1 - (0.95)(1157.1 - 957.09) = 967.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 5 \text{ psia} \\ h_3 = 967.09 \text{ Btu/lbm} \end{array} \right\} \begin{array}{l} x_3 = 0.8364 \\ s_3 = 1.5807 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

Substituting into the energy balance per unit mass flow at the inlet of the turbine, we obtain

$$\begin{aligned}w_{\text{out}} &= (h_1 - h_2) + 0.94(h_2 - h_3) \\ &= (1298.6 - 1157.1) + 0.94(1157.1 - 967.09) = 320.1 \text{ Btu/lbm}\end{aligned}$$

The reversible work output per unit mass flow at the turbine inlet is

$$\begin{aligned}w_{\text{rev}} &= h_1 - h_2 - T_0(s_1 - s_2) + 0.94[h_2 - h_3 - T_0(s_2 - s_3)] \\ &= 1298.6 - 1157.1 - (537)(1.5590 - 1.5646) + 0.94[(1157.1 - 967.09) - (537)(1.5646 - 1.5807)] \\ &= 331.2 \text{ Btu/lbm}\end{aligned}$$

The second law efficiency is then

$$\eta_{\text{II}} = \frac{w_{\text{out}}}{w_{\text{rev}}} = \frac{320.1 \text{ Btu/lbm}}{331.2 \text{ Btu/lbm}} = \mathbf{0.966}$$

**8-102** An electrical radiator is placed in a room and it is turned on for a period of time. The time period for which the heater was on, the exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Kinetic and potential energy changes are negligible. 2 Air is an ideal gas with constant specific heats. 3 The room is well-sealed. 4 Standard atmospheric pressure of 101.3 kPa is assumed.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$  (Table A-2). The properties of oil are given to be  $\rho = 950 \text{ kg/m}^3$ ,  $c_{\text{oil}} = 2.2 \text{ kJ/kg}\cdot\text{K}$ .

**Analysis** (a) The masses of air and oil are

$$m_a = \frac{P_1 V}{RT_1} = \frac{(101.3 \text{ kPa})(50 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(10 + 273 \text{ K})} = 62.36 \text{ kg}$$

$$m_{\text{oil}} = \rho_{\text{oil}} V_{\text{oil}} = (950 \text{ kg/m}^3)(0.030 \text{ m}^3) = 28.50 \text{ kg}$$

An energy balance on the system can be used to determine time period for which the heater was kept on

$$\begin{aligned} (\dot{W}_{\text{in}} - \dot{Q}_{\text{out}})\Delta t &= [mc_v(T_2 - T_1)]_a + [mc(T_2 - T_1)]_{\text{oil}} \\ (1.8 - 0.35 \text{ kW})\Delta t &= [(62.36 \text{ kg})(0.718 \text{ kJ/kg}\cdot^\circ\text{C})(20 - 10)^\circ\text{C}] + [(28.50 \text{ kg})(2.2 \text{ kJ/kg}\cdot^\circ\text{C})(50 - 10)^\circ\text{C}] \\ \Delta t &= \mathbf{2038 \text{ s} = 34 \text{ min}} \end{aligned}$$

(b) The pressure of the air at the final state is

$$P_{a2} = \frac{m_a RT_{a2}}{V} = \frac{(62.36 \text{ kg})(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(20 + 273 \text{ K})}{50 \text{ m}^3} = 104.9 \text{ kPa}$$

The amount of heat transfer to the surroundings is

$$Q_{\text{out}} = \dot{Q}_{\text{out}} \Delta t = (0.35 \text{ kJ/s})(2038 \text{ s}) = 713.5 \text{ kJ}$$

The entropy generation is the sum of the entropy changes of air, oil, and the surroundings

$$\begin{aligned} \Delta S_a &= m \left[ c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right] \\ &= (62.36 \text{ kg}) \left[ (1.005 \text{ kJ/kg}\cdot\text{K}) \ln \frac{(20 + 273) \text{ K}}{(10 + 273) \text{ K}} - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{104.9 \text{ kPa}}{101.3 \text{ kPa}} \right] \\ &= 1.5548 \text{ kJ/K} \\ \Delta S_{\text{oil}} &= mc \ln \frac{T_2}{T_1} = (28.50 \text{ kg})(2.2 \text{ kJ/kg}\cdot\text{K}) \ln \frac{(50 + 273) \text{ K}}{(10 + 273) \text{ K}} = 8.2893 \text{ kJ/K} \\ \Delta S_{\text{surr}} &= \frac{Q_{\text{out}}}{T_{\text{surr}}} = \frac{713.5 \text{ kJ}}{(10 + 273) \text{ K}} = 2.521 \text{ kJ/K} \\ S_{\text{gen}} &= \Delta S_a + \Delta S_{\text{oil}} + \Delta S_{\text{surr}} = 1.5548 + 8.2893 + 2.521 = 12.365 \text{ kJ/K} \end{aligned}$$

The exergy destruction is determined from

$$X_{\text{dest}} = T_0 S_{\text{gen}} = (10 + 273 \text{ K})(12.365 \text{ kJ/K}) = \mathbf{3500 \text{ kJ}}$$

(c) The second-law efficiency may be defined in this case as the ratio of the exergy recovered to the exergy input. That is,

$$\begin{aligned} X_{a,2} &= m[c_v(T_2 - T_1)] - T_0 \Delta S_a \\ &= (62.36 \text{ kg})[(0.718 \text{ kJ/kg}\cdot^\circ\text{C})(20 - 10)^\circ\text{C}] - (10 + 273 \text{ K})(1.5548 \text{ kJ/K}) = 7.729 \text{ kJ} \\ X_{\text{oil},2} &= m[C(T_2 - T_1)] - T_0 \Delta S_a \\ &= (28.50 \text{ kg})[(2.2 \text{ kJ/kg}\cdot^\circ\text{C})(50 - 10)^\circ\text{C}] - (10 + 273 \text{ K})(8.2893 \text{ kJ/K}) = 162.13 \text{ kJ} \\ \eta_{II} &= \frac{X_{\text{recovered}}}{X_{\text{supplied}}} = \frac{X_{a,2} + X_{\text{oil},2}}{\dot{W}_{\text{in}} \Delta t} = \frac{(7.729 + 162.13) \text{ kJ}}{(1.8 \text{ kJ/s})(2038 \text{ s})} = \mathbf{0.046 = 4.6\%} \end{aligned}$$

**8-103** Hot exhaust gases leaving an internal combustion engine is to be used to obtain saturated steam in an adiabatic heat exchanger. The rate at which the steam is obtained, the rate of exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air properties are used for exhaust gases. 4 Pressure drops in the heat exchanger are negligible.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ . The specific heat of air at the average temperature of exhaust gases (650 K) is  $c_p = 1.063 \text{ kJ/kg}\cdot\text{K}$  (Table A-2).

**Analysis** (a) We denote the inlet and exit states of exhaust gases by (1) and (2) and that of the water by (3) and (4). The properties of water are (Table A-4)

$$\begin{aligned} T_3 = 20^\circ\text{C} & \left\{ \begin{aligned} h_3 &= 83.91 \text{ kJ/kg} \\ x_3 = 0 & \left\{ \begin{aligned} s_3 &= 0.29649 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \\ T_4 = 200^\circ\text{C} & \left\{ \begin{aligned} h_4 &= 2792.0 \text{ kJ/kg} \\ x_4 = 1 & \left\{ \begin{aligned} s_4 &= 6.4302 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

An energy balance on the heat exchanger gives

$$\begin{aligned} \dot{m}_a h_1 + \dot{m}_w h_3 &= \dot{m}_a h_2 + \dot{m}_w h_4 \\ \dot{m}_a c_p (T_1 - T_2) &= \dot{m}_w (h_4 - h_3) \\ (0.8 \text{ kg/s})(1.063 \text{ kJ/kg}\cdot^\circ\text{C})(400 - 350)^\circ\text{C} &= \dot{m}_w (2792.0 - 83.91) \text{ kJ/kg} \\ \dot{m}_w &= \mathbf{0.01570 \text{ kg/s}} \end{aligned}$$

(b) The specific exergy changes of each stream as it flows in the heat exchanger is

$$\begin{aligned} \Delta s_a &= c_p \ln \frac{T_2}{T_1} = (0.8 \text{ kg/s})(1.063 \text{ kJ/kg}\cdot\text{K}) \ln \frac{(350 + 273) \text{ K}}{(400 + 273) \text{ K}} = -0.08206 \text{ kJ/kg}\cdot\text{K} \\ \Delta \psi_a &= c_p (T_2 - T_1) - T_0 \Delta s_a \\ &= (1.063 \text{ kJ/kg}\cdot^\circ\text{C})(350 - 400)^\circ\text{C} - (20 + 273 \text{ K})(-0.08206 \text{ kJ/kg}\cdot\text{K}) \\ &= -29.106 \text{ kJ/kg} \\ \Delta \psi_w &= h_4 - h_3 - T_0 (s_4 - s_3) \\ &= (2792.0 - 83.91) \text{ kJ/kg} - (20 + 273 \text{ K})(6.4302 - 0.29649) \text{ kJ/kg}\cdot\text{K} \\ &= 910.913 \text{ kJ/kg} \end{aligned}$$

The exergy destruction is determined from an exergy balance on the heat exchanger to be

$$-\dot{X}_{\text{dest}} = \dot{m}_a \Delta \psi_a + \dot{m}_w \Delta \psi_w = (0.8 \text{ kg/s})(-29.106 \text{ kJ/kg}) + (0.01570 \text{ kg/s})(910.913 \text{ kJ/kg}) = -8.98 \text{ kW}$$

or

$$\dot{X}_{\text{dest}} = \mathbf{8.98 \text{ kW}}$$

(c) The second-law efficiency for a heat exchanger may be defined as the exergy increase of the cold fluid divided by the exergy decrease of the hot fluid. That is,

$$\eta_{\text{II}} = \frac{\dot{m}_w \Delta \psi_w}{-\dot{m}_a \Delta \psi_a} = \frac{(0.01570 \text{ kg/s})(910.913 \text{ kJ/kg})}{-(0.8 \text{ kg/s})(-29.106 \text{ kJ/kg})} = \mathbf{0.614}$$

**8-104** The inner and outer surfaces of a window glass are maintained at specified temperatures. The amount of heat loss and the amount of exergy destruction in 5 h are to be determined

**Assumptions** Steady operating conditions exist since the surface temperatures of the glass remain constant at the specified values.

**Analysis** We take the glass to be the system, which is a closed system. The amount of heat loss is determined from

$$Q = \dot{Q}\Delta t = (4.4 \text{ kJ/s})(5 \times 3600 \text{ s}) = \mathbf{79,200 \text{ kJ}}$$

Under steady conditions, the rate form of the entropy balance for the glass simplifies to

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \overset{\#0}{=} 0$$

$$\frac{\dot{Q}_{\text{in}}}{T_{\text{b,in}}} - \frac{\dot{Q}_{\text{out}}}{T_{\text{b,out}}} + \dot{S}_{\text{gen,glass}} = 0$$

$$\frac{4400 \text{ W}}{283 \text{ K}} - \frac{4400 \text{ W}}{276 \text{ K}} + \dot{S}_{\text{gen,glass}} = 0 \rightarrow \dot{S}_{\text{gen,glass}} = 0.3943 \text{ W/K}$$

Then the amount of entropy generation over a period of 5 h becomes

$$S_{\text{gen,glass}} = \dot{S}_{\text{gen,glass}} \Delta t = (0.3943 \text{ W/K})(5 \times 3600 \text{ s}) = 7098 \text{ J/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (278 \text{ K})(7.098 \text{ kJ/K}) = \mathbf{1973 \text{ kJ}}$$

**Discussion** The total entropy generated during this process can be determined by applying the entropy balance on an *extended system* that includes the glass and its immediate surroundings on both sides so that the boundary temperature of the extended system is the room temperature on one side and the environment temperature on the other side at all times. Using this value of entropy generation will give the total exergy destroyed during the process, including the temperature gradient zones on both sides of the window.

**8-105** Heat is transferred steadily to boiling water in the pan through its bottom. The inner and outer surface temperatures of the bottom of the pan are given. The rate of exergy destruction within the bottom plate is to be determined.

**Assumptions** Steady operating conditions exist since the surface temperatures of the pan remain constant at the specified values.

**Analysis** We take the bottom of the pan to be the system, which is a closed system. Under steady conditions, the rate form of the entropy balance for this system can be expressed as

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \overset{\phi^0}{=} 0$$

$$\frac{\dot{Q}_{\text{in}}}{T_{\text{b,in}}} - \frac{\dot{Q}_{\text{out}}}{T_{\text{b,out}}} + \dot{S}_{\text{gen,system}} = 0$$

$$\frac{800 \text{ W}}{378 \text{ K}} - \frac{800 \text{ W}}{377 \text{ K}} + \dot{S}_{\text{gen,system}} = 0$$

$$\dot{S}_{\text{gen,system}} = 0.00561 \text{ W/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(0.00561 \text{ W/K}) = \mathbf{1.67 \text{ W}}$$

**8-106** A elevation, base area, and the depth of a crater lake are given. The maximum amount of electricity that can be generated by a hydroelectric power plant is to be determined.

**Assumptions** The evaporation of water from the lake is negligible.

**Analysis** The exergy or work potential of the water is the potential energy it possesses relative to the ground level,

$$\text{Exergy} = \text{PE} = mgh$$

Therefore,

$$\begin{aligned} \text{Exergy} = \text{PE} &= \int d\text{PE} = \int gz dm = \int gz(\rho A dz) \\ &= \rho Ag \int_{z_1}^{z_2} z dz = \rho Ag(z_2^2 - z_1^2)/2 \\ &= 0.5(1000 \text{ kg/m}^3)(2 \times 10^4 \text{ m}^2)(9.81 \text{ m/s}^2) \\ &\quad \times ((152 \text{ m})^2 - (140 \text{ m})^2) \left( \frac{1 \text{ h}}{3600 \text{ s}} \right) \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ &= \mathbf{9.55 \times 10^4 \text{ kWh}} \end{aligned}$$

**8-107E** The 2<sup>nd</sup>-law efficiency of a refrigerator and the refrigeration rate are given. The power input to the refrigerator is to be determined.

**Analysis** From the definition of the second law efficiency, the COP of the refrigerator is determined to be

$$\text{COP}_{\text{R,rev}} = \frac{1}{T_H / T_L - 1} = \frac{1}{535 / 495 - 1} = 12.375$$

$$\eta_{\text{II}} = \frac{\text{COP}_{\text{R}}}{\text{COP}_{\text{R,rev}}} \longrightarrow \text{COP}_{\text{R}} = \eta_{\text{II}} \text{COP}_{\text{R,rev}} = 0.45 \times 12.375 = 5.57$$

Thus the power input is

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_{\text{R}}} = \frac{200 \text{ Btu/min}}{5.57} \left( \frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) = \mathbf{0.85 \text{ hp}}$$

**8-108** Writing energy and entropy balances, a relation for the reversible work is to be obtained for a closed system that exchanges heat with surroundings at  $T_0$  in the amount of  $Q_0$  as well as a heat reservoir at temperature  $T_R$  in the amount  $Q_R$ .

**Assumptions** Kinetic and potential changes are negligible.

**Analysis** We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

$$\text{Energy balance: } E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \rightarrow Q_0 + Q_R - W = U_2 - U_1 \longrightarrow W = U_1 - U_2 + Q_0 + Q_R \quad (1)$$

$$\text{Entropy balance: } S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = (S_2 - S_1) + \frac{-Q_R}{T_R} + \frac{-Q_0}{T_0} \quad (2)$$

Solving for  $Q_0$  from (2) and substituting in (1) yields

$$W = (U_1 - U_2) - T_0(S_1 - S_2) - Q_R \left( 1 - \frac{T_0}{T_R} \right) - T_0 S_{\text{gen}}$$

The useful work relation for a closed system is obtained from

$$W_u = W - W_{\text{surr}}$$

$$= (U_1 - U_2) - T_0(S_1 - S_2) - Q_R \left( 1 - \frac{T_0}{T_R} \right) - T_0 S_{\text{gen}} - P_0(\mathcal{V}_2 - \mathcal{V}_1)$$

Then the reversible work relation is obtained by substituting  $S_{\text{gen}} = 0$ ,

$$W_{\text{rev}} = (U_1 - U_2) - T_0(S_1 - S_2) + P_0(\mathcal{V}_1 - \mathcal{V}_2) - Q_R \left( 1 - \frac{T_0}{T_R} \right)$$

A positive result for  $W_{\text{rev}}$  indicates work output, and a negative result work input. Also, the  $Q_R$  is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

**8-109** Writing energy and entropy balances, a relation for the reversible work is to be obtained for a steady-flow system that exchanges heat with surroundings at  $T_0$  at a rate of  $\dot{Q}_0$  as well as a heat reservoir at temperature  $T_R$  in the amount  $\dot{Q}_R$ .

**Analysis** We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

Energy balance:  $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$

$$\dot{Q}_0 + \dot{Q}_R - \dot{W} = \sum \dot{m}_e \left( h_e + \frac{V_e^2}{2} + gz_e \right) - \sum \dot{m}_i \left( h_i + \frac{V_i^2}{2} + gz_i \right)$$

or 
$$\dot{W} = \sum \dot{m}_i \left( h_i + \frac{V_i^2}{2} + gz_i \right) - \sum \dot{m}_e \left( h_e + \frac{V_e^2}{2} + gz_e \right) + \dot{Q}_0 + \dot{Q}_R \quad (1)$$

Entropy balance:

$$\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = \Delta \dot{S}_{\text{system}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

$$\dot{S}_{\text{gen}} = \sum \dot{m}_e s_e - \sum \dot{m}_i s_i + \frac{-\dot{Q}_R}{T_R} + \frac{-\dot{Q}_0}{T_0} \quad (2)$$

Solving for  $\dot{Q}_0$  from (2) and substituting in (1) yields

$$\dot{W} = \sum \dot{m}_i \left( h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum \dot{m}_e \left( h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) - T_0 \dot{S}_{\text{gen}} - \dot{Q}_R \left( 1 - \frac{T_0}{T_R} \right)$$

Then the reversible work relation is obtained by substituting  $\dot{S}_{\text{gen}} = 0$ ,

$$\dot{W}_{\text{rev}} = \sum \dot{m}_i \left( h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum \dot{m}_e \left( h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) - \dot{Q}_R \left( 1 - \frac{T_0}{T_R} \right)$$

A positive result for  $\dot{W}_{\text{rev}}$  indicates work output, and a negative result work input. Also, the  $\dot{Q}_R$  is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

**8-110** Writing energy and entropy balances, a relation for the reversible work is to be obtained for a uniform-flow system that exchanges heat with surroundings at  $T_0$  in the amount of  $Q_0$  as well as a heat reservoir at temperature  $T_R$  in the amount  $Q_R$ .

**Assumptions** Kinetic and potential changes are negligible.

**Analysis** We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

Energy balance:  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$

$$Q_0 + Q_R - W = \sum m_e \left( h_e + \frac{V_e^2}{2} + gz_e \right) - \sum m_i \left( h_i + \frac{V_i^2}{2} + gz_i \right) + (U_2 - U_1)_{\text{cv}}$$

or, 
$$W = \sum m_i \left( h_i + \frac{V_i^2}{2} + gz_i \right) - \sum m_e \left( h_e + \frac{V_e^2}{2} + gz_e \right) - (U_2 - U_1)_{\text{cv}} + Q_0 + Q_R \quad (1)$$

Entropy balance:  $S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$

$$S_{\text{gen}} = (S_2 - S_1)_{\text{cv}} + \sum m_e s_e - \sum m_i s_i + \frac{-Q_R}{T_R} + \frac{-Q_0}{T_0} \quad (2)$$

Solving for  $Q_0$  from (2) and substituting in (1) yields

$$W = \sum m_i \left( h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum m_e \left( h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) + [(U_1 - U_2) - T_0 (S_1 - S_2)]_{\text{cv}} - T_0 S_{\text{gen}} - Q_R \left( 1 - \frac{T_0}{T_R} \right)$$

The useful work relation for a closed system is obtained from

$$W_u = W - W_{\text{surr}} = \sum m_i \left( h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum m_e \left( h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) + [(U_1 - U_2) - T_0 (S_1 - S_2)]_{\text{cv}} - T_0 S_{\text{gen}} - Q_R \left( 1 - \frac{T_0}{T_R} \right) - P_0 (V_2 - V_1)$$

Then the reversible work relation is obtained by substituting  $S_{\text{gen}} = 0$ ,

$$W_{\text{rev}} = \sum m_i \left( h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum m_e \left( h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) + [(U_1 - U_2) - T_0 (S_1 - S_2) + P_0 (V_1 - V_2)]_{\text{cv}} - Q_R \left( 1 - \frac{T_0}{T_R} \right)$$

A positive result for  $W_{\text{rev}}$  indicates work output, and a negative result work input. Also, the  $Q_R$  is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

**8-111** An electric resistance heater is immersed in water. The time it will take for the electric heater to raise the water temperature to a specified temperature, the minimum work input, and the exergy destroyed during this process are to be determined.

**Assumptions** 1 Water is an incompressible substance with constant specific heats. 2 The energy stored in the container itself and the heater is negligible. 3 Heat loss from the container is negligible. 4 The environment temperature is given to be  $T_0 = 20^\circ\text{C}$ .

**Properties** The specific heat of water at room temperature is  $c = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-3).

**Analysis** Taking the water in the container as the system, which is a closed system, the energy balance can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$W_{\text{e,in}} = (\Delta U)_{\text{water}}$$

$$\dot{W}_{\text{e,in}} \Delta t = mc(T_2 - T_1)_{\text{water}}$$

Substituting,

$$(800 \text{ J/s})\Delta t = (40 \text{ kg})(4180 \text{ J/kg}\cdot^\circ\text{C})(80 - 20)^\circ\text{C}$$

Solving for  $\Delta t$  gives

$$\Delta t = 12,544 \text{ s} = 209.1 \text{ min} = 3.484 \text{ h}$$

Again we take the water in the tank to be the system. Noting that no heat or mass crosses the boundaries of this system and the energy and entropy contents of the heater are negligible, the entropy balance for it can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$0 + S_{\text{gen}} = \Delta S_{\text{water}}$$

Therefore, the entropy generated during this process is

$$S_{\text{gen}} = \Delta S_{\text{water}} = mc \ln \frac{T_2}{T_1} = (40 \text{ kg})(4.184 \text{ kJ/kg}\cdot\text{K}) \ln \frac{353 \text{ K}}{293 \text{ K}} = 31.18 \text{ kJ/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(31.18 \text{ kJ/K}) = 9136 \text{ kJ}$$

The actual work input for this process is

$$W_{\text{act,in}} = \dot{W}_{\text{act,in}} \Delta t = (0.8 \text{ kJ/s})(12,552 \text{ s}) = 10,042 \text{ kJ}$$

Then the reversible (or minimum required) work input becomes

$$W_{\text{rev,in}} = W_{\text{act,in}} - X_{\text{destroyed}} = 10,042 - 9136 = 906 \text{ kJ}$$

**8-112** A hot water pipe at a specified temperature is losing heat to the surrounding air at a specified rate. The rate at which the work potential is wasted during this process is to be determined.

**Assumptions** Steady operating conditions exist.

**Analysis** We take the air in the vicinity of the pipe (excluding the pipe) as our system, which is a closed system. The system extends from the outer surface of the pipe to a distance at which the temperature drops to the surroundings temperature. In steady operation, the rate form of the entropy balance for this system can be expressed as

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \stackrel{\text{Eq. 0}}{=} 0$$

$$\frac{\dot{Q}_{\text{in}}}{T_{\text{b,in}}} - \frac{\dot{Q}_{\text{out}}}{T_{\text{b,out}}} + \dot{S}_{\text{gen,system}} = 0$$

$$\frac{1175 \text{ W}}{353 \text{ K}} - \frac{1175 \text{ W}}{278 \text{ K}} + \dot{S}_{\text{gen,system}} = 0 \rightarrow \dot{S}_{\text{gen,system}} = 0.8980 \text{ W/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (278 \text{ K})(0.8980 \text{ W/K}) = \mathbf{250 \text{ W}}$$

**8-113** Air expands in an adiabatic turbine from a specified state to another specified state. The second-law efficiency is to be determined.

**Assumptions 1** This is a steady-flow process since there is no change with time. **2** The device is adiabatic and thus heat transfer is negligible. **3** Air is an ideal gas with constant specific heats. **4** Kinetic and potential energy changes are negligible.

**Properties** At the average temperature of  $(425 + 325)/2 = 375$  K, the constant pressure specific heat of air is  $c_p = 1.011$  kJ/kg·K (Table A-2b). The gas constant of air is  $R = 0.287$  kJ/kg·K (Table A-1).

**Analysis** There is only one inlet and one exit, and thus  $\dot{m}_1 = \dot{m}_2 = \dot{m}$ . We take the turbine as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \overset{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 = \dot{W}_{\text{out}} + \dot{m}h_2$$

$$\dot{W}_{\text{out}} = \dot{m}(h_1 - h_2)$$

$$w_{\text{out}} = c_p(T_1 - T_2)$$

Substituting,

$$w_{\text{out}} = c_p(T_1 - T_2) = (1.011 \text{ kJ/kg} \cdot \text{K})(425 - 325) \text{ K} = 101.1 \text{ kJ/kg}$$

The entropy change of air is

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.011 \text{ kJ/kg} \cdot \text{K}) \ln \frac{325 \text{ K}}{425 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{110 \text{ kPa}}{550 \text{ kPa}} \\ &= 0.1907 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The maximum (reversible) work is the exergy difference between the inlet and exit states

$$\begin{aligned} w_{\text{rev,out}} &= c_p(T_1 - T_2) - T_0(s_1 - s_2) \\ &= w_{\text{out}} - T_0(s_1 - s_2) \\ &= 101.1 \text{ kJ/kg} - (298 \text{ K})(-0.1907 \text{ kJ/kg} \cdot \text{K}) \\ &= \mathbf{157.9 \text{ kJ/kg}} \end{aligned}$$

The second law efficiency is then

$$\eta_{\text{II}} = \frac{w_{\text{out}}}{w_{\text{rev,out}}} = \frac{101.1 \text{ kJ/kg}}{157.9 \text{ kJ/kg}} = \mathbf{0.640}$$

**8-114** Steam is accelerated in a nozzle. The actual and maximum outlet velocities are to be determined.

**Assumptions 1** The nozzle operates steadily. **2** The changes in potential energies are negligible.

**Properties** The properties of steam at the inlet and the exit of the nozzle are (Tables A-4 through A-6)

$$\begin{aligned} P_1 &= 500 \text{ kPa} \quad \left. \begin{array}{l} h_1 = 2855.8 \text{ kJ/kg} \\ T_1 = 200^\circ\text{C} \end{array} \right\} s_1 = 7.0610 \text{ kJ/kg} \cdot \text{K} \\ P_2 &= 200 \text{ kPa} \quad \left. \begin{array}{l} h_2 = 2706.3 \text{ kJ/kg} \\ x_2 = 1 \text{ (sat. vapor)} \end{array} \right\} s_2 = 7.1270 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

**Analysis** We take the nozzle to be the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\dot{\Delta E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \overset{\phi=0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}(h_1 + V_1^2/2) = \dot{m}(h_2 + V_2^2/2)$$

$$\frac{V_2^2 - V_1^2}{2} = h_1 - h_2 = \Delta \text{ke}_{\text{actual}}$$

Substituting,

$$\Delta \text{ke}_{\text{actual}} = h_1 - h_2 = 2855.8 - 2706.3 = 149.5 \text{ kJ/kg}$$

The actual velocity at the exit is then

$$\frac{V_2^2 - V_1^2}{2} = \Delta \text{ke}_{\text{actual}}$$

$$V_2 = \sqrt{V_1^2 + 2\Delta \text{ke}_{\text{actual}}} = \sqrt{(30 \text{ m/s})^2 + 2(149.5 \text{ kJ/kg}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{547.6 \text{ m/s}}$$

The maximum kinetic energy change is determined from

$$\Delta \text{ke}_{\text{max}} = h_1 - h_2 - T_0(s_1 - s_2) = 2855.8 - 2706.3 - (298)(7.0610 - 7.1270) = 169.2 \text{ kJ/kg}$$

The maximum velocity at the exit is then

$$\frac{V_{2,\text{max}}^2 - V_1^2}{2} = \Delta \text{ke}_{\text{max}}$$

$$V_{2,\text{max}} = \sqrt{V_1^2 + 2\Delta \text{ke}_{\text{max}}} = \sqrt{(30 \text{ m/s})^2 + 2(169.2 \text{ kJ/kg}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$= \mathbf{582.5 \text{ m/s}}$$

**8-115** A throttle valve is placed in the steam line supplying the turbine inlet in order to control an isentropic steam turbine. The second-law efficiency of this system when the valve is partially open to when it is fully open is to be compared.

**Assumptions** **1** This is a steady-flow process since there is no change with time. **2** The turbine is well-insulated, and there is no heat transfer from the turbine.

### Analysis

#### Valve is fully open:

The properties of steam at various states are

$$\left. \begin{array}{l} P_1 = P_2 = 6 \text{ MPa} \\ T_1 = T_2 = 700^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = h_2 = 3894.3 \text{ kJ/kg} \\ s_1 = s_2 = 7.4247 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_3 = 70 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} x_3 = 0.9914 \\ h_3 = 2639.7 \text{ kJ/kg} \end{array}$$

The second law efficiency of the entire system is then

$$\eta_{II} = \frac{w_{\text{out}}}{w_{\text{rev}}} = \frac{h_1 - h_3}{h_1 - h_3 - T_0(s_1 - s_3)} = \frac{h_1 - h_3}{h_1 - h_3} = \mathbf{1.0}$$

since  $s_1 = s_3$  for this system.

#### Valve is partly open:

$$\left. \begin{array}{l} P_2 = 3 \text{ MPa} \\ h_2 = h_1 = 3894.3 \text{ kJ/kg} \end{array} \right\} s_2 = 7.7405 \text{ kJ/kg} \cdot \text{K} \quad (\text{from EES})$$

$$\left. \begin{array}{l} P_3 = 70 \text{ kPa} \\ s_3 = s_2 \end{array} \right\} h_3 = 2760.8 \text{ kJ/kg} \quad (\text{from EES})$$

$$\eta_{II} = \frac{w_{\text{out}}}{w_{\text{rev}}} = \frac{h_1 - h_3}{h_1 - h_3 - T_0(s_1 - s_3)} = \frac{3894.3 - 2760.8}{3894.3 - 2760.8 - (298)(7.4247 - 7.7405)} = \mathbf{0.923}$$

**8-116** Two rigid tanks that contain water at different states are connected by a valve. The valve is opened and steam flows from tank A to tank B until the pressure in tank A drops to a specified value. Tank B loses heat to the surroundings. The final temperature in each tank and the work potential wasted during this process are to be determined.

**Assumptions** **1** Tank A is insulated and thus heat transfer is negligible. **2** The water that remains in tank A undergoes a reversible adiabatic process. **3** The thermal energy stored in the tanks themselves is negligible. **4** The system is stationary and thus kinetic and potential energy changes are negligible. **5** There are no work interactions.

**Analysis** (a) The steam in tank A undergoes a reversible, adiabatic process, and thus  $s_2 = s_1$ . From the steam tables (Tables A-4 through A-6),

**Tank A :**

$$P_1 = 400 \text{ kPa} \quad \left\{ \begin{array}{l} v_{1,A} = v_f + x_1 v_{fg} = 0.001084 + (0.8)(0.46242 - 0.001084) = 0.37015 \text{ m}^3/\text{kg} \\ u_{1,A} = u_f + x_1 u_{fg} = 604.22 + (0.8)(1948.9) = 2163.3 \text{ kJ/kg} \\ s_{1,A} = s_f + x_1 s_{fg} = 1.7765 + (0.8)(5.1191) = 5.8717 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$T_{2,A} = T_{\text{sat}@300 \text{ kPa}} = \mathbf{133.52^\circ \text{C}}$$

$$\begin{array}{l} P_2 = 300 \text{ kPa} \\ s_2 = s_1 \\ (\text{sat. mixture}) \end{array} \left\{ \begin{array}{l} x_{2,A} = \frac{s_{2,A} - s_f}{s_{fg}} = \frac{5.8717 - 1.6717}{5.3200} = 0.7895 \\ v_{2,A} = v_f + x_{2,A} v_{fg} = 0.001073 + (0.7895)(0.60582 - 0.001073) = 0.47850 \text{ m}^3/\text{kg} \\ u_{2,A} = u_f + x_{2,A} u_{fg} = 561.11 + (0.7895)(1982.1 \text{ kJ/kg}) = 2125.9 \text{ kJ/kg} \end{array} \right.$$

**Tank B :**

$$\begin{array}{l} P_1 = 200 \text{ kPa} \\ T_1 = 250^\circ \text{C} \end{array} \left\{ \begin{array}{l} v_{1,B} = 1.1989 \text{ m}^3/\text{kg} \\ u_{1,B} = 2731.4 \text{ kJ/kg} \\ s_{1,B} = 7.7100 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

The initial and the final masses in tank A are

$$m_{1,A} = \frac{V_A}{v_{1,A}} = \frac{0.2 \text{ m}^3}{0.37015 \text{ m}^3/\text{kg}} = 0.5403 \text{ kg}$$

and

$$m_{2,A} = \frac{V_A}{v_{2,A}} = \frac{0.2 \text{ m}^3}{0.479 \text{ m}^3/\text{kg}} = 0.4180 \text{ kg}$$

Thus,  $0.540 - 0.418 = 0.122 \text{ kg}$  of mass flows into tank B. Then,

$$m_{2,B} = m_{1,B} - 0.122 = 3 + 0.122 = 3.122 \text{ kg}$$

The final specific volume of steam in tank B is determined from

$$v_{2,B} = \frac{V_B}{m_{2,B}} = \frac{(m_1 v_1)_B}{m_{2,B}} = \frac{(3 \text{ kg})(1.1989 \text{ m}^3/\text{kg})}{3.122 \text{ m}^3} = 1.152 \text{ m}^3/\text{kg}$$

We take the entire contents of both tanks as the system, which is a closed system. The energy balance for this stationary closed system can be expressed as

$$\begin{array}{l} \underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}} \\ -Q_{\text{out}} = \Delta U = (\Delta U)_A + (\Delta U)_B \quad (\text{since } W = \text{KE} = \text{PE} = 0) \\ -Q_{\text{out}} = (m_2 u_2 - m_1 u_1)_A + (m_2 u_2 - m_1 u_1)_B \end{array}$$

Substituting,

$$-900 = \{(0.418)(2125.9) - (0.5403)(2163.3)\} + \{(3.122)u_{2,B} - (3)(2731.4)\}$$

$$u_{2,B} = 2425.9 \text{ kJ/kg}$$

Thus,

$$\left. \begin{aligned} v_{2,B} &= 1.152 \text{ m}^3/\text{kg} \\ u_{2,B} &= 2425.9 \text{ kJ/kg} \end{aligned} \right\} \begin{aligned} T_{2,B} &= \mathbf{110.1^\circ\text{C}} \\ s_{2,B} &= 6.9772 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

(b) The total entropy generation during this process is determined by applying the entropy balance on an *extended system* that includes both tanks and their immediate surroundings so that the boundary temperature of the extended system is the temperature of the surroundings at all times. It gives

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$-\frac{Q_{\text{out}}}{T_{\text{b,surr}}} + S_{\text{gen}} = \Delta S_A + \Delta S_B$$

Rearranging and substituting, the total entropy generated during this process is determined to be

$$S_{\text{gen}} = \Delta S_A + \Delta S_B + \frac{Q_{\text{out}}}{T_{\text{b,surr}}} = (m_2 s_2 - m_1 s_1)_A + (m_2 s_2 - m_1 s_1)_B + \frac{Q_{\text{out}}}{T_{\text{b,surr}}}$$

$$= \{(0.418)(5.8717) - (0.5403)(5.8717)\} + \{(3.122)(6.9772) - (3)(7.7100)\} + \frac{900 \text{ kJ}}{273 \text{ K}}$$

$$= 1.234 \text{ kJ/K}$$

The work potential wasted is equivalent to the exergy destroyed during a process, which can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (273 \text{ K})(1.234 \text{ kJ/K}) = \mathbf{337 \text{ kJ}}$$

**8-117E** A cylinder initially filled with helium gas at a specified state is compressed polytropically to a specified temperature and pressure. The actual work consumed and the minimum useful work input needed are to be determined.

**Assumptions** 1 Helium is an ideal gas with constant specific heats. 2 The cylinder is stationary and thus the kinetic and potential energy changes are negligible. 3 The thermal energy stored in the cylinder itself is negligible. 4 The compression or expansion process is quasi-equilibrium. 5 The environment temperature is 70°F.

**Properties** The gas constant of helium is  $R = 2.6805 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R} = 0.4961 \text{ Btu/lbm} \cdot \text{R}$  (Table A-1E). The specific heats of helium are  $c_v = 0.753$  and  $c_p = 1.25 \text{ Btu/lbm} \cdot \text{R}$  (Table A-2E).

**Analysis** (a) Helium at specified conditions can be treated as an ideal gas. The mass of helium is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(25 \text{ psia})(15 \text{ ft}^3)}{(2.6805 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(530 \text{ R})} = 0.264 \text{ lbm}$$

The exponent  $n$  and the boundary work for this polytropic process are determined to be

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2} \longrightarrow V_2 = \frac{T_2}{T_1} \frac{P_1}{P_2} V_1 = \frac{(760 \text{ R})(25 \text{ psia})}{(530 \text{ R})(70 \text{ psia})} (15 \text{ ft}^3) = 7.682 \text{ ft}^3$$

$$P_2 V_2^n = P_1 V_1^n \longrightarrow \left( \frac{P_2}{P_1} \right) = \left( \frac{V_1}{V_2} \right)^n \longrightarrow \left( \frac{70}{25} \right) = \left( \frac{15}{7.682} \right)^n \longrightarrow n = 1.539$$

Then the boundary work for this polytropic process can be determined from

$$\begin{aligned} W_{b,\text{in}} &= -\int_1^2 P dV = -\frac{P_2 V_2 - P_1 V_1}{1-n} = -\frac{mR(T_2 - T_1)}{1-n} \\ &= -\frac{(0.264 \text{ lbm})(0.4961 \text{ Btu/lbm} \cdot \text{R})(760 - 530) \text{ R}}{1 - 1.539} = 55.9 \text{ Btu} \end{aligned}$$

Also,

$$W_{\text{surr},\text{in}} = -P_0(V_2 - V_1) = -(14.7 \text{ psia})(7.682 - 15) \text{ ft}^3 \left( \frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) = 19.9 \text{ Btu}$$

Thus,

$$W_{u,\text{in}} = W_{b,\text{in}} - W_{\text{surr},\text{in}} = 55.9 - 19.9 = \mathbf{36.0 \text{ Btu}}$$

(b) We take the helium in the cylinder as the system, which is a closed system. Taking the direction of heat transfer to be from the cylinder, the energy balance for this stationary closed system can be expressed as

$$\begin{aligned} \underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} &= \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}} \\ -Q_{\text{out}} + W_{b,\text{in}} &= \Delta U = m(u_2 - u_1) \\ -Q_{\text{out}} &= m(u_2 - u_1) - W_{b,\text{in}} \\ Q_{\text{out}} &= W_{b,\text{in}} - mc_v(T_2 - T_1) \end{aligned}$$

Substituting,

$$Q_{\text{out}} = 55.9 \text{ Btu} - (0.264 \text{ lbm})(0.753 \text{ Btu/lbm} \cdot \text{R})(760 - 530) \text{ R} = 10.2 \text{ Btu}$$

The total entropy generation during this process is determined by applying the entropy balance on an *extended system* that includes the cylinder and its immediate surroundings so that the boundary temperature of the extended system is the temperature of the surroundings at all times. It gives

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} = \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$-\frac{Q_{\text{out}}}{T_{\text{b,surr}}} + S_{\text{gen}} = \Delta S_{\text{sys}}$$

where the entropy change of helium is

$$\begin{aligned}\Delta S_{\text{sys}} = \Delta S_{\text{helium}} &= m \left( c_{p,\text{avg}} \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) \\ &= (0.264 \text{ lbm}) \left[ (1.25 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{760 \text{ R}}{530 \text{ R}} - (0.4961 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{70 \text{ psia}}{25 \text{ psia}} \right] \\ &= -0.0159 \text{ Btu/R}\end{aligned}$$

Rearranging and substituting, the total entropy generated during this process is determined to be

$$S_{\text{gen}} = \Delta S_{\text{helium}} + \frac{Q_{\text{out}}}{T_0} = (-0.0159 \text{ Btu/R}) + \frac{10.2 \text{ Btu}}{530 \text{ R}} = 0.003345 \text{ Btu/R}$$

The work potential wasted is equivalent to the exergy destroyed during a process, which can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (530 \text{ R})(0.003345 \text{ Btu/R}) = 1.77 \text{ Btu}$$

The minimum work with which this process could be accomplished is the reversible work input,  $W_{\text{rev,in}}$ , which can be determined directly from

$$W_{\text{rev,in}} = W_{\text{act,in}} - X_{\text{destroyed}} = 36.0 - 1.77 = \mathbf{34.23 \text{ Btu}}$$

**Discussion** The reversible work input, which represents the minimum work input  $W_{\text{rev,in}}$  in this case can be determined from the exergy balance by setting the exergy destruction term equal to zero,

$$\underbrace{X_{\text{in}} - X_{\text{out}}}_{\text{Net exergy transfer by heat, work, and mass}} - \underbrace{X_{\text{destroyed}}}_{\text{Exergy destruction}} \stackrel{\text{no (reversible)}}{=} \underbrace{\Delta X_{\text{system}}}_{\text{Change in exergy}} \rightarrow W_{\text{rev,in}} = X_2 - X_1$$

Substituting the closed system exergy relation, the reversible work input during this process is determined to be

$$\begin{aligned}W_{\text{rev}} &= (U_2 - U_1) - T_0 (S_2 - S_1) + P_0 (V_2 - V_1) \\ &= (0.264 \text{ lbm})(0.753 \text{ Btu/lbm} \cdot \text{R})(300 - 70)^\circ\text{F} - (530 \text{ R})(-0.0159 \text{ Btu/R}) \\ &\quad + (14.7 \text{ psia})(7.682 - 15) \text{ ft}^3 [\text{Btu}/5.4039 \text{ psia} \cdot \text{ft}^3] \\ &= \mathbf{34.24 \text{ Btu}}\end{aligned}$$

**8-118** Steam expands in a two-stage adiabatic turbine from a specified state to specified pressure. Some steam is extracted at the end of the first stage. The wasted power potential is to be determined.

**Assumptions 1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** The turbine is adiabatic and thus heat transfer is negligible. **4** The environment temperature is given to be  $T_0 = 25^\circ\text{C}$ .

**Analysis** The wasted power potential is equivalent to the rate of exergy destruction during a process, which can be determined from an exergy balance or directly from its definition  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ .

The total rate of entropy generation during this process is determined by taking the entire turbine, which is a control volume, as the system and applying the entropy balance. Noting that this is a steady-flow process and there is no heat transfer,

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \overset{\varphi 0}{=} 0$$

$$\dot{m}_1 s_1 - \dot{m}_2 s_2 - \dot{m}_3 s_3 + \dot{S}_{\text{gen}} = 0$$

$$\dot{m}_1 s_1 - 0.1 \dot{m}_1 s_2 - 0.9 \dot{m}_1 s_3 + \dot{S}_{\text{gen}} = 0 \rightarrow \dot{S}_{\text{gen}} = \dot{m}_1 [0.9 s_3 + 0.1 s_2 - s_1]$$

and  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = T_0 \dot{m}_1 [0.9 s_3 + 0.1 s_2 - s_1]$

From the steam tables (Tables A-4 through 6)

$$\left. \begin{array}{l} P_1 = 9 \text{ MPa} \\ T_1 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 3387.4 \text{ kJ/kg} \\ s_1 = 6.6603 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1.4 \text{ MPa} \\ s_{2s} = s_1 \end{array} \right\} h_{2s} = 2882.4 \text{ kJ/kg}$$

and,

$$\eta_T = \frac{h_1 - h_2}{h_1 - h_{2s}} \rightarrow h_2 = h_1 - \eta_T (h_1 - h_{2s})$$

$$= 3387.4 - 0.88(3387.4 - 2882.4)$$

$$= 2943.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 1.4 \text{ MPa} \\ h_2 = 2943.0 \text{ kJ/kg} \end{array} \right\} s_2 = 6.7776 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_3 = 50 \text{ kPa} \\ s_{3s} = s_1 \end{array} \right\} \begin{array}{l} x_{3s} = \frac{s_{3s} - s_f}{s_{fg}} = \frac{6.6603 - 1.0912}{6.5019} = 0.8565 \\ h_{3s} = h_f + x_{3s} h_{fg} = 340.54 + 0.8565 \times 2304.7 = 2314.6 \text{ kJ/kg} \end{array}$$

and  $\eta_T = \frac{h_1 - h_3}{h_1 - h_{3s}} \rightarrow h_3 = h_1 - \eta_T (h_1 - h_{3s})$

$$= 3387.4 - 0.88(3387.4 - 2314.6)$$

$$= 2443.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 50 \text{ kPa} \\ h_3 = 2443.3 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} x_3 = \frac{h_3 - h_f}{h_{fg}} = \frac{2443.3 - 340.54}{2304.7} = 0.9124 \\ s_3 = s_f + x_3 s_{fg} = 1.0912 + 0.9124 \times 6.5019 = 7.0235 \text{ kJ/kg} \cdot \text{K} \end{array}$$

Substituting, the wasted work potential is determined to be

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(15 \text{ kg/s})(0.9 \times 7.0235 + 0.1 \times 6.7776 - 6.6603) \text{ kJ/kg} = \mathbf{1514 \text{ kW}}$$

**8-119** Steam expands in a two-stage adiabatic turbine from a specified state to another specified state. Steam is reheated between the stages. For a given power output, the reversible power output and the rate of exergy destruction are to be determined.

**Assumptions 1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** The turbine is adiabatic and thus heat transfer is negligible. **4** The environment temperature is given to be  $T_0 = 25^\circ\text{C}$ .

**Properties** From the steam tables (Tables A-4 through 6)

$$\left. \begin{array}{l} P_1 = 8 \text{ MPa} \\ T_1 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 3399.5 \text{ kJ/kg} \\ s_1 = 6.7266 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 2 \text{ MPa} \\ T_2 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_2 = 3137.7 \text{ kJ/kg} \\ s_2 = 6.9583 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_3 = 2 \text{ MPa} \\ T_3 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3468.3 \text{ kJ/kg} \\ s_3 = 7.4337 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 30 \text{ kPa} \\ x_4 = 0.97 \end{array} \right\} \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 289.27 + 0.97 \times 2335.3 = 2554.5 \text{ kJ/kg} \\ s_4 = s_f + x_4 s_{fg} = 0.9441 + 0.97 \times 6.8234 = 7.5628 \text{ kJ/kg} \cdot \text{K} \end{array}$$

**Analysis** We take the entire turbine, excluding the reheat section, as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 + \dot{m}h_3 = \dot{m}h_2 + \dot{m}h_4 + \dot{W}_{\text{out}}$$

$$\dot{W}_{\text{out}} = \dot{m}[(h_1 - h_2) + (h_3 - h_4)]$$

Substituting, the mass flow rate of the steam is determined from the steady-flow energy equation applied to the actual process,

$$\dot{m} = \frac{\dot{W}_{\text{out}}}{h_1 - h_2 + h_3 - h_4} = \frac{5000 \text{ kJ/s}}{(3399.5 - 3137.7 + 3468.3 - 2554.5) \text{ kJ/kg}} = 4.253 \text{ kg/s}$$

The reversible (or maximum) power output is determined from the rate form of the exergy balance applied on the turbine and setting the exergy destruction term equal to zero,

$$\begin{aligned}
 \underbrace{\dot{X}_{\text{in}} - \dot{X}_{\text{out}}}_{\text{Rate of net exergy transfer by heat, work, and mass}} - \underbrace{\dot{X}_{\text{destroyed}}}_{\text{Rate of exergy destruction}} \overset{\text{reversible}}{\overset{\text{70}}{=}} \underbrace{\Delta \dot{X}_{\text{system}}}_{\text{Rate of change of exergy}} \overset{\text{steady}}{\overset{\text{70}}{=}} 0 \\
 \dot{X}_{\text{in}} = \dot{X}_{\text{out}} \\
 \dot{m}\psi_1 + \dot{m}\psi_3 = \dot{m}\psi_2 + \dot{m}\psi_4 + \dot{W}_{\text{rev,out}} \\
 \dot{W}_{\text{rev,out}} = \dot{m}(\psi_1 - \psi_2) + \dot{m}(\psi_3 - \psi_4) \\
 = \dot{m}[(h_1 - h_2) + T_0(s_2 - s_1) - \Delta \text{ke}^{\text{70}} - \Delta \text{pe}^{\text{70}}] \\
 + \dot{m}[(h_3 - h_4) + T_0(s_4 - s_3) - \Delta \text{ke}^{\text{70}} - \Delta \text{pe}^{\text{70}}]
 \end{aligned}$$

Then the reversible power becomes

$$\begin{aligned}
 \dot{W}_{\text{rev,out}} &= \dot{m}[h_1 - h_2 + h_3 - h_4 + T_0(s_2 - s_1 + s_4 - s_3)] \\
 &= (4.253 \text{ kg/s})[(3399.5 - 3137.7 + 3468.3 - 2554.5) \text{ kJ/kg} \\
 &\quad + (298 \text{ K})(6.9583 - 6.7266 + 7.5628 - 7.4337) \text{ kJ/kg} \cdot \text{K}] \\
 &= \mathbf{5457 \text{ kW}}
 \end{aligned}$$

Then the rate of exergy destruction is determined from its definition,

$$\dot{X}_{\text{destroyed}} = \dot{W}_{\text{rev,out}} - \dot{W}_{\text{out}} = 5457 - 5000 = \mathbf{457 \text{ kW}}$$

**8-120** One ton of liquid water at 80°C is brought into a room. The final equilibrium temperature in the room and the entropy generated are to be determined.

**Assumptions** **1** The room is well insulated and well sealed. **2** The thermal properties of water and air are constant at room temperature. **3** The system is stationary and thus the kinetic and potential energy changes are zero. **4** There are no work interactions involved.

**Properties** The gas constant of air is  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$  (Table A-1). The constant volume specific heat of water at room temperature is  $c_v = 0.718 \text{ kJ/kg} \cdot ^\circ\text{C}$  (Table A-2). The specific heat of water at room temperature is  $c = 4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$  (Table A-3).

**Analysis** The volume and the mass of the air in the room are

$$V = 4 \times 5 \times 6 = 120 \text{ m}^3$$

$$m_{\text{air}} = \frac{P_1 V_1}{R T_1} = \frac{(100 \text{ kPa})(120 \text{ m}^3)}{(0.2870 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(295 \text{ K})} = 141.74 \text{ kg}$$

Taking the contents of the room, including the water, as our system, the energy balance can be written as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$0 = \Delta U = (\Delta U)_{\text{water}} + (\Delta U)_{\text{air}}$$

$$\text{or} \quad [mc(T_2 - T_1)]_{\text{water}} + [mc_v(T_2 - T_1)]_{\text{air}} = 0$$

$$\text{Substituting,} \quad (1000 \text{ kg})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(T_f - 80)^\circ\text{C} + (141.74 \text{ kg})(0.718 \text{ kJ/kg} \cdot ^\circ\text{C})(T_f - 22)^\circ\text{C} = 0$$

It gives the final equilibrium temperature in the room to be

$$T_f = 78.6^\circ\text{C}$$

(b) We again take the room and the water in it as the system, which is a closed system. Considering that the system is well-insulated and no mass is entering and leaving, the entropy balance for this system can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} = \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} = \Delta S_{\text{air}} + \Delta S_{\text{water}}$$

where

$$\Delta S_{\text{air}} = mc_v \ln \frac{T_2}{T_1} + mR \ln \frac{V_2}{V_1} = (141.74 \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K}) \ln \frac{351.6 \text{ K}}{295 \text{ K}} = 17.87 \text{ kJ/K}$$

$$\Delta S_{\text{water}} = mc \ln \frac{T_2}{T_1} = (1000 \text{ kg})(4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{351.6 \text{ K}}{353 \text{ K}} = -16.36 \text{ kJ/K}$$

Substituting, the entropy generation is determined to be

$$S_{\text{gen}} = 17.87 - 16.36 = 1.51 \text{ kJ/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (283 \text{ K})(1.51 \text{ kJ/K}) = 427 \text{ kJ}$$

(c) The work potential (the maximum amount of work that can be produced) during a process is simply the reversible work output. Noting that the actual work for this process is zero, it becomes

$$X_{\text{destroyed}} = W_{\text{rev,out}} - W_{\text{act,out}} \rightarrow W_{\text{rev,out}} = X_{\text{destroyed}} = 427 \text{ kJ}$$

**8-121** An insulated cylinder is divided into two parts. One side of the cylinder contains  $N_2$  gas and the other side contains He gas at different states. The final equilibrium temperature in the cylinder and the wasted work potential are to be determined for the cases of piston being fixed and moving freely.

**Assumptions** **1** Both  $N_2$  and He are ideal gases with constant specific heats. **2** The energy stored in the container itself is negligible. **3** The cylinder is well-insulated and thus heat transfer is negligible.

**Properties** The gas constants and the constant volume specific heats are  $R = 0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  is  $c_v = 0.743 \text{ kJ/kg}\cdot^\circ\text{C}$  for  $N_2$ , and  $R = 2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  is  $c_v = 3.1156 \text{ kJ/kg}\cdot^\circ\text{C}$  for He (Tables A-1 and A-2)

**Analysis** The mass of each gas in the cylinder is

$$m_{N_2} = \left( \frac{P_1 V_1}{RT_1} \right)_{N_2} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(353 \text{ K})} = 4.77 \text{ kg}$$

$$m_{He} = \left( \frac{P_1 V_1}{RT_1} \right)_{He} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(298 \text{ K})} = 0.808 \text{ kg}$$

Taking the entire contents of the cylinder as our system, the 1st law relation can be written as

$$\underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{system}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$0 = \Delta U = (\Delta U)_{N_2} + (\Delta U)_{He}$$

$$0 = [mc_v(T_2 - T_1)]_{N_2} + [mc_v(T_2 - T_1)]_{He}$$

Substituting,

$$(4.77 \text{ kg})(0.743 \text{ kJ/kg}\cdot^\circ\text{C})(T_f - 80)^\circ\text{C} + (0.808 \text{ kg})(3.1156 \text{ kJ/kg}\cdot^\circ\text{C})(T_f - 25)^\circ\text{C} = 0$$

It gives

$$T_f = 57.2^\circ\text{C}$$

where  $T_f$  is the final equilibrium temperature in the cylinder.

The answer would be the **same** if the piston were not free to move since it would effect only pressure, and not the specific heats.

(b) We take the entire cylinder as our system, which is a closed system. Noting that the cylinder is well-insulated and thus there is no heat transfer, the entropy balance for this closed system can be expressed as

$$\underbrace{S_{in} - S_{out}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{gen}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{system}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$0 + S_{gen} = \Delta S_{N_2} + \Delta S_{He}$$

But first we determine the final pressure in the cylinder:

$$N_{total} = N_{N_2} + N_{He} = \left( \frac{m}{M} \right)_{N_2} + \left( \frac{m}{M} \right)_{He} = \frac{4.77 \text{ kg}}{28 \text{ kg/kmol}} + \frac{0.808 \text{ kg}}{4 \text{ kg/kmol}} = 0.372 \text{ kmol}$$

$$P_2 = \frac{N_{total} R_u T}{V_{total}} = \frac{(0.372 \text{ kmol})(8.314 \text{ kPa}\cdot\text{m}^3/\text{kmol}\cdot\text{K})(330.2 \text{ K})}{2 \text{ m}^3} = 510.6 \text{ kPa}$$

Then,

$$\begin{aligned}\Delta S_{N_2} &= m \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{N_2} \\ &= (4.77 \text{ kg}) \left[ (1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{330.2 \text{ K}}{353 \text{ K}} - (0.2968 \text{ kJ/kg} \cdot \text{K}) \ln \frac{510.6 \text{ kPa}}{500 \text{ kPa}} \right] = -0.361 \text{ kJ/K}\end{aligned}$$

$$\begin{aligned}\Delta S_{He} &= m \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{He} \\ &= (0.808 \text{ kg}) \left[ (5.1926 \text{ kJ/kg} \cdot \text{K}) \ln \frac{330.2 \text{ K}}{298 \text{ K}} - (2.0769 \text{ kJ/kg} \cdot \text{K}) \ln \frac{510.6 \text{ kPa}}{500 \text{ kPa}} \right] = 0.395 \text{ kJ/K}\end{aligned}$$

$$S_{\text{gen}} = \Delta S_{N_2} + \Delta S_{He} = -0.361 + 0.395 = 0.034 \text{ kJ/K}$$

The wasted work potential is equivalent to the exergy destroyed during a process, and it can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.034 \text{ kJ/K}) = \mathbf{10.1 \text{ kJ}}$$

If the piston were not free to move, we would still have  $T_2 = 330.2 \text{ K}$  but the volume of each gas would remain constant in this case:

$$\Delta S_{N_2} = m \left( c_v \ln \frac{T_2}{T_1} - R \ln \frac{v_2}{v_1} \right)_{N_2}^{\phi^0} = (4.77 \text{ kg})(0.743 \text{ kJ/kg} \cdot \text{K}) \ln \frac{330.2 \text{ K}}{353 \text{ K}} = -0.237 \text{ kJ/K}$$

$$\Delta S_{He} = m \left( c_v \ln \frac{T_2}{T_1} - R \ln \frac{v_2}{v_1} \right)_{He}^{\phi^0} = (0.808 \text{ kg})(3.1156 \text{ kJ/kg} \cdot \text{K}) \ln \frac{330.2 \text{ K}}{298 \text{ K}} = 0.258 \text{ kJ/K}$$

$$S_{\text{gen}} = \Delta S_{N_2} + \Delta S_{He} = -0.237 + 0.258 = 0.021 \text{ kJ/K}$$

and

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.021 \text{ kJ/K}) = \mathbf{6.26 \text{ kJ}}$$

**8-122** An insulated cylinder is divided into two parts. One side of the cylinder contains  $N_2$  gas and the other side contains He gas at different states. The final equilibrium temperature in the cylinder and the wasted work potential are to be determined for the cases of piston being fixed and moving freely.  $\checkmark$

**Assumptions** 1 Both  $N_2$  and He are ideal gases with constant specific heats. 2 The energy stored in the container itself, except the piston, is negligible. 3 The cylinder is well-insulated and thus heat transfer is negligible. 4 Initially, the piston is at the average temperature of the two gases.

**Properties** The gas constants and the constant volume specific heats are  $R = 0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  is  $c_v = 0.743 \text{ kJ/kg}\cdot^\circ\text{C}$  for  $N_2$ , and  $R = 2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  is  $c_v = 3.1156 \text{ kJ/kg}\cdot^\circ\text{C}$  for He (Tables A-1 and A-2). The specific heat of copper piston is  $c = 0.386 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-3).

**Analysis** The mass of each gas in the cylinder is

$$m_{N_2} = \left( \frac{P_1 V_1}{RT_1} \right)_{N_2} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(353 \text{ K})} = 4.77 \text{ kg}$$

$$m_{He} = \left( \frac{P_1 V_1}{RT_1} \right)_{He} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(353 \text{ K})} = 0.808 \text{ kg}$$

Taking the entire contents of the cylinder as our system, the 1st law relation can be written as

$$\begin{aligned} \underbrace{E_{in} - E_{out}}_{\text{Net energy transfer by heat, work, and mass}} &= \underbrace{\Delta E_{system}}_{\text{Change in internal, kinetic, potential, etc. energies}} \\ 0 = \Delta U &= (\Delta U)_{N_2} + (\Delta U)_{He} + (\Delta U)_{Cu} \\ 0 &= [mc_v(T_2 - T_1)]_{N_2} + [mc_v(T_2 - T_1)]_{He} + [mc(T_2 - T_1)]_{Cu} \end{aligned}$$

where

$$T_{1,Cu} = (80 + 25) / 2 = 52.5^\circ\text{C}$$

Substituting,

$$\begin{aligned} (4.77 \text{ kg})(0.743 \text{ kJ/kg}\cdot^\circ\text{C})(T_f - 80)^\circ\text{C} &+ (0.808 \text{ kg})(3.1156 \text{ kJ/kg}\cdot^\circ\text{C})(T_f - 25)^\circ\text{C} \\ &+ (5.0 \text{ kg})(0.386 \text{ kJ/kg}\cdot^\circ\text{C})(T_f - 52.5)^\circ\text{C} = 0 \end{aligned}$$

It gives

$$T_f = 56.0^\circ\text{C}$$

where  $T_f$  is the final equilibrium temperature in the cylinder.

The answer would be the **same** if the piston were not free to move since it would effect only pressure, and not the specific heats.

(b) We take the entire cylinder as our system, which is a closed system. Noting that the cylinder is well-insulated and thus there is no heat transfer, the entropy balance for this closed system can be expressed as

$$\begin{aligned} \underbrace{S_{in} - S_{out}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{gen}}_{\text{Entropy generation}} &= \underbrace{\Delta S_{system}}_{\text{Change in entropy}} \\ 0 + S_{gen} &= \Delta S_{N_2} + \Delta S_{He} + \Delta S_{piston} \end{aligned}$$

But first we determine the final pressure in the cylinder:

$$N_{\text{total}} = N_{\text{N}_2} + N_{\text{He}} = \left(\frac{m}{M}\right)_{\text{N}_2} + \left(\frac{m}{M}\right)_{\text{He}} = \frac{4.77 \text{ kg}}{28 \text{ kg/kmol}} + \frac{0.808 \text{ kg}}{4 \text{ kg/kmol}} = 0.372 \text{ kmol}$$

$$P_2 = \frac{N_{\text{total}} R_u T}{V_{\text{total}}} = \frac{(0.372 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(329 \text{ K})}{2 \text{ m}^3} = 508.8 \text{ kPa}$$

Then,

$$\begin{aligned} \Delta S_{\text{N}_2} &= m \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{\text{N}_2} \\ &= (4.77 \text{ kg}) \left[ (1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} - (0.2968 \text{ kJ/kg} \cdot \text{K}) \ln \frac{508.8 \text{ kPa}}{500 \text{ kPa}} \right] = -0.374 \text{ kJ/K} \\ \Delta S_{\text{He}} &= m \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{\text{He}} \\ &= (0.808 \text{ kg}) \left[ (5.1926 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} - (2.0769 \text{ kJ/kg} \cdot \text{K}) \ln \frac{508.8 \text{ kPa}}{500 \text{ kPa}} \right] = 0.386 \text{ kJ/K} \\ \Delta S_{\text{piston}} &= \left( mc \ln \frac{T_2}{T_1} \right)_{\text{piston}} = (5 \text{ kg})(0.386 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{325.5 \text{ K}} = 0.021 \text{ kJ/K} \\ S_{\text{gen}} &= \Delta S_{\text{N}_2} + \Delta S_{\text{He}} + \Delta S_{\text{piston}} = -0.374 + 0.386 + 0.021 = 0.0334 \text{ kJ/K} \end{aligned}$$

The wasted work potential is equivalent to the exergy destroyed during a process, and it can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.033 \text{ kJ/K}) = \mathbf{9.83 \text{ kJ}}$$

If the piston were not free to move, we would still have  $T_2 = 330.2 \text{ K}$  but the volume of each gas would remain constant in this case:

$$\begin{aligned} \Delta S_{\text{N}_2} &= m \left( c_v \ln \frac{T_2}{T_1} - R \ln \frac{v_2}{v_1} \right)_{\text{N}_2}^{\phi^0} = (4.77 \text{ kg})(0.743 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} = -0.250 \text{ kJ/K} \\ \Delta S_{\text{He}} &= m \left( c_v \ln \frac{T_2}{T_1} - R \ln \frac{v_2}{v_1} \right)_{\text{He}}^{\phi^0} = (0.808 \text{ kg})(3.1156 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} = 0.249 \text{ kJ/K} \\ S_{\text{gen}} &= \Delta S_{\text{N}_2} + \Delta S_{\text{He}} + \Delta S_{\text{piston}} = -0.250 + 0.249 + 0.021 = \mathbf{0.020 \text{ kJ/K}} \end{aligned}$$

and

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.020 \text{ kJ/K}) = \mathbf{6.0 \text{ kJ}}$$

**8-123E** Argon enters an adiabatic turbine at a specified state with a specified mass flow rate, and leaves at a specified pressure. The isentropic efficiency of turbine is to be determined.

**Assumptions 1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** The device is adiabatic and thus heat transfer is negligible. **4** Argon is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of argon is  $k = 1.667$ . The constant pressure specific heat of argon is  $c_p = 0.1253 \text{ Btu/lbm}\cdot\text{R}$  (Table A-2E).

**Analysis** There is only one inlet and one exit, and thus  $\dot{m}_1 = \dot{m}_2 = \dot{m}$ . We take the isentropic turbine as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 = \dot{W}_{s,\text{out}} + \dot{m}h_{2s} \quad (\text{since } \dot{Q} \cong \Delta ke \cong \Delta pe \cong 0)$$

$$\dot{W}_{s,\text{out}} = \dot{m}(h_1 - h_{2s})$$

From the isentropic relations,

$$T_{2s} = T_1 \left( \frac{P_{2s}}{P_1} \right)^{(k-1)/k} = (1960 \text{ R}) \left( \frac{30 \text{ psia}}{200 \text{ psia}} \right)^{0.667/1.667} = 917.5 \text{ R}$$

Then the power output of the isentropic turbine becomes

$$\dot{W}_{s,\text{out}} = \dot{m}c_p(T_1 - T_{2s}) = (40 \text{ lbm/min})(0.1253 \text{ Btu/lbm}\cdot\text{R})(1960 - 917.5)\text{R} \left( \frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) = 123.2 \text{ hp}$$

Then the isentropic efficiency of the turbine is determined from

$$\eta_T = \frac{\dot{W}_{a,\text{out}}}{\dot{W}_{s,\text{out}}} = \frac{95 \text{ hp}}{123.2 \text{ hp}} = 0.771 = 77.1\%$$

(b) Using the steady-flow energy balance relation  $\dot{W}_{a,\text{out}} = \dot{m}c_p(T_1 - T_2)$  above, the actual turbine exit temperature is determined to be

$$T_2 = T_1 - \frac{\dot{W}_{a,\text{out}}}{\dot{m}c_p} = 1500 - \frac{95 \text{ hp}}{(40 \text{ lbm/min})(0.1253 \text{ Btu/lbm}\cdot\text{R})} \left( \frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) = 696.1^\circ\text{F} = 1156.1 \text{ R}$$

The entropy generation during this process can be determined from an entropy balance on the turbine,

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \stackrel{\text{no}}{=} 0$$

$$\dot{m}s_1 - \dot{m}s_2 + \dot{S}_{\text{gen}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{m}(s_2 - s_1)$$

where

$$\begin{aligned}
 s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\
 &= (0.1253 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{1156.1 \text{ R}}{1960 \text{ R}} - (0.04971 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{30 \text{ psia}}{200 \text{ psia}} \\
 &= 0.02816 \text{ Btu/lbm} \cdot \text{R}
 \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ ,

$$\begin{aligned}
 \dot{X}_{\text{destroyed}} &= T_0 \dot{S}_{\text{gen}} = \dot{m} T_0 (s_2 - s_1) \\
 &= (40 \text{ lbm/min})(537 \text{ R})(0.02816 \text{ Btu/lbm} \cdot \text{R}) \left( \frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) \\
 &= 14.3 \text{ hp}
 \end{aligned}$$

Then the reversible power and second-law efficiency become

$$\dot{W}_{\text{rev,out}} = \dot{W}_{a,\text{out}} + \dot{X}_{\text{destroyed}} = 95 + 14.3 = 109.3 \text{ hp}$$

and

$$\eta_{\text{II}} = \frac{\dot{W}}{\dot{W}_{\text{rev}}} = \frac{95 \text{ hp}}{109.3 \text{ hp}} = \mathbf{86.9\%}$$

**8-124** The feedwater of a steam power plant is preheated using steam extracted from the turbine. The ratio of the mass flow rates of the extracted steam and the feedwater are to be determined.

**Assumptions 1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** Heat loss from the device to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid.

**Properties** The properties of steam and feedwater are (Tables A-4 through A-6)

$$\left. \begin{array}{l} P_1 = 1 \text{ MPa} \\ T_1 = 200^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 2828.3 \text{ kJ/kg} \\ s_1 = 6.6956 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_2 = h_{f@1 \text{ MPa}} = 762.51 \text{ kJ/kg} \\ s_2 = s_{f@1 \text{ MPa}} = 2.1381 \text{ kJ/kg} \cdot \text{K} \\ T_2 = 179.88^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} P_3 = 2.5 \text{ MPa} \\ T_3 = 50^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 \cong h_{f@50^\circ\text{C}} = 209.34 \text{ kJ/kg} \\ s_3 \cong s_{f@50^\circ\text{C}} = 0.7038 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2.5 \text{ MPa} \\ T_4 = T_2 - 10^\circ\text{C} \cong 170^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 \cong h_{f@170^\circ\text{C}} = 719.08 \text{ kJ/kg} \\ s_4 \cong s_{f@170^\circ\text{C}} = 2.0417 \text{ kJ/kg} \cdot \text{K} \end{array}$$

**Analysis (a)** We take the heat exchanger as the system, which is a control volume. The mass and energy balances for this steady-flow system can be expressed in the rate form as follows:

**Mass balance** (for each fluid stream):

$$\dot{m}_{\text{in}} - \dot{m}_{\text{out}} = \Delta \dot{m}_{\text{system}} \stackrel{\approx 0}{=} 0 \rightarrow \dot{m}_{\text{in}} = \dot{m}_{\text{out}} \rightarrow \dot{m}_1 = \dot{m}_2 = \dot{m}_s \quad \text{and} \quad \dot{m}_3 = \dot{m}_4 = \dot{m}_{fw}$$

**Energy balance** (for the heat exchanger):

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} \stackrel{\approx 0}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 = \dot{m}_2 h_2 + \dot{m}_4 h_4 \quad (\text{since } \dot{Q} = \dot{W} = \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

Combining the two,  $\dot{m}_s (h_2 - h_1) = \dot{m}_{fw} (h_3 - h_4)$

Dividing by  $\dot{m}_{fw}$  and substituting,

$$\frac{\dot{m}_s}{\dot{m}_{fw}} = \frac{h_3 - h_4}{h_2 - h_1} = \frac{(209.34 - 719.08) \text{ kJ/kg}}{(762.51 - 2828.3) \text{ kJ/kg}} = \mathbf{0.247}$$

**(b)** The entropy generation during this process per unit mass of feedwater can be determined from an entropy balance on the feedwater heater expressed in the rate form as

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\substack{\text{Rate of net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{\dot{S}_{\text{gen}}}_{\substack{\text{Rate of entropy} \\ \text{generation}}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\substack{\text{Rate of change} \\ \text{of entropy}}} \stackrel{\approx 0}{=} 0$$

$$\dot{m}_1 s_1 - \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_4 s_4 + \dot{S}_{\text{gen}} = 0$$

$$\dot{m}_s (s_1 - s_2) + \dot{m}_{fw} (s_3 - s_4) + \dot{S}_{\text{gen}} = 0$$

$$\frac{\dot{S}_{\text{gen}}}{\dot{m}_{fw}} = \frac{\dot{m}_s}{\dot{m}_{fw}} (s_2 - s_1) + (s_4 - s_3) = (0.247)(2.1381 - 6.6956) + (2.0417 - 0.7038) = 0.213 \text{ kJ/K} \cdot \text{kg fw}$$

Noting that this process involves no actual work, the reversible work and exergy destruction become equivalent since  $X_{\text{destroyed}} = W_{\text{rev,out}} - W_{\text{act,out}} \rightarrow W_{\text{rev,out}} = X_{\text{destroyed}}$ . The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.213 \text{ kJ/K} \cdot \text{kg fw}) = \mathbf{63.5 \text{ kJ/kg feedwater}}$$

**8-125 EES** Problem 8-124 is reconsidered. The effect of the state of the steam at the inlet of the feedwater heater on the ratio of mass flow rates and the reversible power is to be investigated.

**Analysis** Using EES, the problem is solved as follows:

"Input Data"

"Steam (let st=steam data):"

Fluid\$='Steam\_IAPWS'

T\_st[1]=200 [C]

{P\_st[1]=1000 [kPa]}

P\_st[2] = P\_st[1]

x\_st[2]=0 "saturated liquid, quality = 0%"

T\_st[2]=temperature(steam, P=P\_st[2], x=x\_st[2])

"Feedwater (let fw=feedwater data):"

T\_fw[1]=50 [C]

P\_fw[1]=2500 [kPa]

P\_fw[2]=P\_fw[1] "assume no pressure drop for the feedwater"

T\_fw[2]=T\_st[2]-10

"Surroundings:"

T\_o = 25 [C]

P\_o = 100 [kPa] "Assumed value for the surroundings pressure"

"Conservation of mass:"

"There is one entrance, one exit for both the steam and feedwater."

"Steam: m\_dot\_st[1] = m\_dot\_st[2]"

"Feedwater: m\_dot\_fw[1] = m\_dot\_fw[2]"

"Let m\_ratio = m\_dot\_st/m\_dot\_fw"

"Conservation of Energy:"

"We write the conservation of energy for steady-flow control volume having two entrances and two exits with the above assumptions. Since neither of the flow rates is known or can be found, write the conservation of energy per unit mass of the feedwater."

E\_in - E\_out = DELTAE\_cv

DELTA E\_cv=0 "Steady-flow requirement"

E\_in = m\_ratio\*h\_st[1] + h\_fw[1]

h\_st[1]=enthalpy(Fluid\$, T=T\_st[1], P=P\_st[1])

h\_fw[1]=enthalpy(Fluid\$, T=T\_fw[1], P=P\_fw[1])

E\_out = m\_ratio\*h\_st[2] + h\_fw[2]

h\_fw[2]=enthalpy(Fluid\$, T=T\_fw[2], P=P\_fw[2])

**8-126** A 1-ton (1000 kg) of water is to be cooled in a tank by pouring ice into it. The final equilibrium temperature in the tank and the exergy destruction are to be determined.

**Assumptions** 1 Thermal properties of the ice and water are constant. 2 Heat transfer to the water tank is negligible. 3 There is no stirring by hand or a mechanical device (it will add energy).

**Properties** The specific heat of water at room temperature is  $c = 4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$ , and the specific heat of ice at about  $0^\circ\text{C}$  is  $c = 2.11 \text{ kJ/kg} \cdot ^\circ\text{C}$  (Table A-3). The melting temperature and the heat of fusion of ice at 1 atm are  $0^\circ\text{C}$  and  $333.7 \text{ kJ/kg}$ .

**Analysis** (a) We take the ice and the water as the system, and disregard any heat transfer between the system and the surroundings. Then the energy balance for this process can be written as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$0 = \Delta U$$

$$0 = \Delta U_{\text{ice}} + \Delta U_{\text{water}}$$

$$[mc(0^\circ\text{C} - T_1)_{\text{solid}} + mh_{\text{if}} + mc(T_2 - 0^\circ\text{C})_{\text{liquid}}]_{\text{ice}} + [mc(T_2 - T_1)]_{\text{water}} = 0$$

Substituting,

$$(80 \text{ kg}) \{ (2.11 \text{ kJ/kg} \cdot ^\circ\text{C}) [0 - (-5)]^\circ\text{C} + 333.7 \text{ kJ/kg} + (4.18 \text{ kJ/kg} \cdot ^\circ\text{C}) (T_2 - 0^\circ\text{C}) \} \\ + (1000 \text{ kg}) (4.18 \text{ kJ/kg} \cdot ^\circ\text{C}) (T_2 - 20^\circ\text{C}) = 0$$

It gives  $T_2 = 12.42^\circ\text{C}$

which is the final equilibrium temperature in the tank.

(b) We take the ice and the water as our system, which is a closed system. Considering that the tank is well-insulated and thus there is no heat transfer, the entropy balance for this closed system can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} = \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} = \Delta S_{\text{ice}} + \Delta S_{\text{water}}$$

where

$$\Delta S_{\text{water}} = \left( mc \ln \frac{T_2}{T_1} \right)_{\text{water}} = (1000 \text{ kg}) (4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{285.42 \text{ K}}{293 \text{ K}} = -109.590 \text{ kJ/K}$$

$$\Delta S_{\text{ice}} = (\Delta S_{\text{solid}} + \Delta S_{\text{melting}} + \Delta S_{\text{liquid}})_{\text{ice}}$$

$$= \left( \left( mc \ln \frac{T_{\text{melting}}}{T_1} \right)_{\text{solid}} + \frac{mh_{\text{ig}}}{T_{\text{melting}}} + \left( mc \ln \frac{T_2}{T_1} \right)_{\text{liquid}} \right)_{\text{ice}}$$

$$= (80 \text{ kg}) \left( (2.11 \text{ kJ/kg} \cdot \text{K}) \ln \frac{273 \text{ K}}{268 \text{ K}} + \frac{333.7 \text{ kJ/kg}}{273 \text{ K}} + (4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{285.42 \text{ K}}{273 \text{ K}} \right)$$

$$= 115.783 \text{ kJ/K}$$

$$\text{Then, } S_{\text{gen}} = \Delta S_{\text{water}} + \Delta S_{\text{ice}} = -109.590 + 115.783 = 6.193 \text{ kJ/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K}) (6.193 \text{ kJ/K}) = \mathbf{1815 \text{ kJ}}$$

**8-127** An evacuated bottle is surrounded by atmospheric air. A valve is opened, and air is allowed to fill the bottle. The amount of heat transfer through the wall of the bottle when thermal and mechanical equilibrium is established and the amount of exergy destroyed are to be determined.

**Assumptions** **1** This is an unsteady process since the conditions within the device are changing during the process, but it can be analyzed as a uniform-flow process since the state of fluid at the inlet remains constant. **2** Air is an ideal gas. **3** Kinetic and potential energies are negligible. **4** There are no work interactions involved. **5** The direction of heat transfer is to the air in the bottle (will be verified).

**Properties** The gas constant of air is  $0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  (Table A-1).

**Analysis** We take the bottle as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy  $h$  and internal energy  $u$ , respectively, the mass and energy balances can be expressed as

**Mass balance:**  $m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_i = m_2$  (since  $m_{\text{out}} = m_{\text{initial}} = 0$ )

**Energy balance:**

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} + m_i h_i = m_2 u_2 \quad (\text{since } W \cong E_{\text{out}} = E_{\text{initial}} = \text{ke} \cong \text{pe} \cong 0)$$

**Combining the two balances:**

$$Q_{\text{in}} = m_2 (u_2 - h_i)$$

where

$$m_2 = \frac{P_2 V}{RT_2} = \frac{(100 \text{ kPa})(0.012 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(290 \text{ K})} = 0.0144 \text{ kg}$$

$$T_i = T_2 = 290 \text{ K} \xrightarrow{\text{Table A-17}} \begin{matrix} h_i = 290.16 \text{ kJ/kg} \\ u_2 = 206.91 \text{ kJ/kg} \end{matrix}$$

Substituting,

$$Q_{\text{in}} = (0.0144 \text{ kg})(206.91 - 290.16) \text{ kJ/kg} = -1.2 \text{ kJ} \rightarrow Q_{\text{out}} = \mathbf{1.2 \text{ kJ}}$$

Note that the negative sign for heat transfer indicates that the assumed direction is wrong. Therefore, we reversed the direction.

The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the bottle and its immediate surroundings so that the boundary temperature of the extended system is the temperature of the surroundings at all times. The entropy balance for it can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$m_i s_i - \frac{Q_{\text{out}}}{T_{\text{b,in}}} + S_{\text{gen}} = \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1 \stackrel{\text{Eq. 0}}{=} m_2 s_2$$

Therefore, the total entropy generated during this process is

$$S_{\text{gen}} = -m_i s_i + m_2 s_2 + \frac{Q_{\text{out}}}{T_{\text{b,out}}} = m_2 (s_2 - s_i) \stackrel{\text{Eq. 0}}{=} \frac{Q_{\text{out}}}{T_{\text{b,out}}} = \frac{Q_{\text{out}}}{T_{\text{surr}}} = \frac{1.2 \text{ kJ}}{290 \text{ K}} = 0.00415 \text{ kJ/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (290 \text{ K})(0.00415 \text{ kJ/K}) = \mathbf{1.2 \text{ kJ}}$$

**8-128** A heat engine operates between two tanks filled with air at different temperatures. The maximum work that can be produced and the final temperatures of the tanks are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of air is  $0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  (Table A-1). The constant volume specific heat of air at room temperature is  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$  (Table A-2).

**Analysis** For maximum power production, the entropy generation must be zero. We take the two tanks (the heat source and heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} = \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} = \Delta S_{\text{tank,source}} + \Delta S_{\text{tank,sink}} + \Delta S_{\text{heat engine}}$$

$$\Delta S_{\text{tank,source}} + \Delta S_{\text{tank,sink}} = 0$$

$$\left( mc_v \ln \frac{T_2}{T_1} + mR \ln \frac{v_2}{v_1} \right)_{\text{source}} + \left( mc_v \ln \frac{T_2}{T_1} + mR \ln \frac{v_2}{v_1} \right)_{\text{sink}} = 0$$

$$\ln \frac{T_2}{T_{1A}} \frac{T_2}{T_{1B}} = 0 \longrightarrow T_2^2 = T_{1A} T_{1B}$$

where  $T_{1A}$  and  $T_{1B}$  are the initial temperatures of the source and the sink, respectively, and  $T_2$  is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = \sqrt{T_{1A} T_{1B}} = \sqrt{(900 \text{ K})(300 \text{ K})} = \mathbf{519.6 \text{ K}}$$

The energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  for the source and sink can be expressed as follows:

*Source:*

$$-Q_{\text{source,out}} = \Delta U = mc_v(T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = mc_v(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_v(T_{1A} - T_2) = (30 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(900 - 519.6) \text{ K} = 8193 \text{ kJ}$$

*Sink:*

$$Q_{\text{sink,in}} = mc_v(T_2 - T_{1B}) = (30 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(519.6 - 300) \text{ K} = 4731 \text{ kJ}$$

Then the work produced in this case becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 8193 - 4731 = \mathbf{3463 \text{ kJ}}$$

Therefore, a maximum of 3463 kJ of work can be produced during this process.

**8-129** A heat engine operates between two constant-pressure cylinders filled with air at different temperatures. The maximum work that can be produced and the final temperatures of the cylinders are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of air is  $0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  (Table A-1). The constant pressure specific heat of air at room temperature is  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2).

**Analysis** For maximum power production, the entropy generation must be zero. We take the two cylinders (the heat source and heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} = \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} = \Delta S_{\text{cylinder,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}}$$

$$\Delta S_{\text{cylinder,source}} + \Delta S_{\text{cylinder,sink}} = 0$$

$$\left( mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{source}} + 0 + \left( mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{sink}} = 0$$

$$\ln \frac{T_2}{T_{1A}} \frac{T_2}{T_{1B}} = 0 \longrightarrow T_2^2 = T_{1A} T_{1B}$$

where  $T_{1A}$  and  $T_{1B}$  are the initial temperatures of the source and the sink, respectively, and  $T_2$  is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = \sqrt{T_{1A} T_{1B}} = \sqrt{(900 \text{ K})(300 \text{ K})} = \mathbf{519.6 \text{ K}}$$

The energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  for the source and sink can be expressed as follows:

*Source:*

$$-Q_{\text{source,out}} + W_{b,\text{in}} = \Delta U \rightarrow Q_{\text{source,out}} = \Delta H = mc_p (T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_p (T_{1A} - T_2) = (30 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(900 - 519.6) \text{ K} = 11,469 \text{ kJ}$$

*Sink:*

$$Q_{\text{sink,in}} - W_{b,\text{out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p (T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p (T_2 - T_{1B}) = (30 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(519.6 - 300) \text{ K} = 6621 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 11,469 - 6621 = \mathbf{4847 \text{ kJ}}$$

Therefore, a maximum of 4847 kJ of work can be produced during this process

**8-130** A heat engine operates between a nitrogen tank and an argon cylinder at different temperatures. The maximum work that can be produced and the final temperatures are to be determined.

**Assumptions** Nitrogen and argon are ideal gases with constant specific heats at room temperature.

**Properties** The constant volume specific heat of nitrogen at room temperature is  $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$ . The constant pressure specific heat of argon at room temperature is  $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$  (Table A-2).

**Analysis** For maximum power production, the entropy generation must be zero. We take the tank, the cylinder (the heat source and the heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} \overset{\approx 0}{=} \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} \overset{\approx 0}{=} \Delta S_{\text{tank,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}} \overset{\approx 0}{=}$$

$$(\Delta S)_{\text{source}} + (\Delta S)_{\text{sink}} = 0$$

$$\left( mc_v \ln \frac{T_2}{T_1} - mR \ln \frac{v_2}{v_1} \right)_{\text{source}}^{\approx 0} + 0 + \left( mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{sink}}^{\approx 0} = 0$$

Substituting,

$$(20 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K}) \ln \frac{T_2}{1000 \text{ K}} + (10 \text{ kg})(0.5203 \text{ kJ/kg}\cdot\text{K}) \ln \frac{T_2}{300 \text{ K}} = 0$$

Solving for  $T_2$  yields

$$T_2 = \mathbf{731.8 \text{ K}}$$

where  $T_2$  is the common final temperature of the tanks for maximum power production.

The energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  for the source and sink can be expressed as follows:

*Source:*

$$-Q_{\text{source,out}} = \Delta U = mc_v(T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = mc_v(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_v(T_{1A} - T_2) = (20 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K})(1000 - 731.8)\text{K} = 3985 \text{ kJ}$$

*Sink:*

$$Q_{\text{sink,in}} - W_{\text{b,out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p(T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p(T_2 - T_{1A}) = (10 \text{ kg})(0.5203 \text{ kJ/kg}\cdot\text{K})(731.8 - 300)\text{K} = 2247 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 3985 - 2247 = \mathbf{1739 \text{ kJ}}$$

Therefore, a maximum of 1739 kJ of work can be produced during this process

**8-131** A rigid tank containing nitrogen is considered. Heat is now transferred to the nitrogen from a reservoir and nitrogen is allowed to escape until the mass of nitrogen becomes one-half of its initial mass. The change in the nitrogen's work potential is to be determined.

**Assumptions 1** This is an unsteady process since the conditions within the device are changing during the process. **2** Kinetic and potential energies are negligible. **3** There are no work interactions involved. **4** Nitrogen is an ideal gas with constant specific heats.

**Properties** The properties of nitrogen at room temperature are  $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The initial and final masses in the tank are

$$m_1 = \frac{P_1 V}{RT_1} = \frac{(1000 \text{ kPa})(0.100 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 1.150 \text{ kg}$$

$$m_2 = m_e = \frac{m_1}{2} = \frac{1.150 \text{ kg}}{2} = 0.575 \text{ kg}$$

The final temperature in the tank is

$$T_2 = \frac{P_2 V}{m_2 R} = \frac{(1000 \text{ kPa})(0.100 \text{ m}^3)}{(0.575 \text{ kg})(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})} = 586 \text{ K}$$

We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy  $h$  and internal energy  $u$ , respectively, the mass and energy balances for this uniform-flow system can be expressed as

**Mass balance:**

$$m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_2$$

**Energy balance:**

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$Q_{\text{in}} - m_e h_e = m_2 u_2 - m_1 u_1$$

$$Q_{\text{out}} = m_e h_e + m_2 u_2 - m_1 u_1$$

Using the average of the initial and final temperatures for the exiting nitrogen,

$T_e = 0.5(T_1 + T_2) = 0.5((293 + 586) = 439.5 \text{ K}$  this energy balance equation becomes

$$\begin{aligned} Q_{\text{out}} &= m_e h_e + m_2 u_2 - m_1 u_1 \\ &= m_e c_p T_e + m_2 c_v T_2 - m_1 c_v T_1 \\ &= (0.575)(1.039)(439.5) + (0.575)(0.743)(586) - (1.150)(0.743)(293) \\ &= 262.6 \text{ kJ} \end{aligned}$$

The work potential associated with this process is equal to the exergy destroyed during the process. The exergy destruction during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ . The entropy generation  $S_{\text{gen}}$  in this case is determined from an entropy balance on the system:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\frac{Q_{\text{in}}}{T_R} - m_e s_e + S_{\text{gen}} = \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1$$

$$S_{\text{gen}} = m_2 s_2 - m_1 s_1 + m_e s_e - \frac{Q_{\text{in}}}{T_R}$$

Noting that pressures are same, rearranging and substituting gives

$$\begin{aligned} S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e - \frac{Q_{\text{in}}}{T_R} \\ &= m_2 c_p \ln T_2 - m_1 c_p \ln T_1 + m_e c_p \ln T_e - \frac{Q_{\text{in}}}{T_R} \\ &= (0.575)(1.039) \ln(586) - (1.150)(1.039) \ln(293) + (0.575)(1.039) \ln(439.5) - \frac{262.6}{673} \\ &= 0.2661 \text{ kJ/K} \end{aligned}$$

Then,

$$W_{\text{rev}} = X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(0.2661 \text{ kJ/K}) = \mathbf{78.0 \text{ kJ}}$$

### Alternative More Accurate Solution

This problem may also be solved by considering the variation of gas temperature at the outlet of the tank. The mass and energy balances are

$$\begin{aligned} \dot{m}_e &= -\frac{dm}{dt} \\ \dot{Q} &= \frac{d(mu)}{dt} - h \frac{dm}{dt} = \frac{c_v d(mT)}{dt} - c_p T \frac{dm}{dt} \end{aligned}$$

Combining these expressions and replacing  $T$  in the last term gives

$$\dot{Q} = c_v \frac{d(mT)}{dt} - \frac{c_p P V}{Rm} \frac{dm}{dt}$$

Integrating this over the time required to release one-half the mass produces

$$Q = c_v (m_2 T_2 - m_1 T_1) - \frac{c_p P V}{R} \ln \frac{m_2}{m_1}$$

The reduced combined first and second law becomes

$$\dot{W}_{\text{rev}} = \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

when the mass balance is substituted and the entropy generation is set to zero (for maximum work production). Expanding the system time derivative gives

$$\begin{aligned}
\dot{W}_{\text{rev}} &= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - \frac{d(mu - T_0 ms)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - \frac{d(mu)}{dt} + T_0 m \frac{ds}{dt} + T_0 s \frac{dm}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - \frac{d(mu)}{dt} + h \frac{dm}{dt} + m \frac{T_0}{T} \frac{dh}{dt}
\end{aligned}$$

Substituting  $\dot{Q}$  from the first law,

$$\begin{aligned}
\dot{W}_{\text{rev}} &= \left[ \frac{d(mu)}{dt} - h \frac{dm}{dt} \right] \left( 1 - \frac{T_0}{T_R} \right) - \left[ \frac{d(mu)}{dt} - h \frac{dm}{dt} \right] + m \frac{T_0}{T} \frac{dh}{dt} \\
&= - \frac{T_0}{T_R} \left[ \frac{d(mu)}{dt} - h \frac{dm}{dt} - m \frac{dh}{dt} \right] \\
&= - \frac{T_0}{T_R} \left[ c_v \frac{d(mT)}{dt} - c_p T \frac{dm}{dt} - m c_p \frac{dT}{dt} \right]
\end{aligned}$$

At any time,

$$T = \frac{P\mathcal{V}}{mR}$$

which further reduces this result to

$$\dot{W}_{\text{rev}} = \frac{T_0}{T_R} c_p \frac{P\mathcal{V}}{mR} \frac{dm}{dt} + T_0 m \left( \frac{c_p}{T} \frac{dT}{dt} - \frac{R}{P} \frac{dP}{dt} \right)$$

When this is integrated over the time to complete the process, the result is

$$\begin{aligned}
W_{\text{rev}} &= \frac{T_0}{T_R} \frac{c_p P\mathcal{V}}{R} \ln \frac{m_2}{m_1} + T_0 \frac{c_p P\mathcal{V}}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \\
&= \frac{293}{673} \frac{(1.039)(1000)(0.100)}{0.2968} \ln \frac{1}{2} + (293) \frac{(1.039)(1000)(0.100)}{0.2968} \left( \frac{1}{293} - \frac{1}{586} \right) \\
&= \mathbf{69.4 \text{ kJ}}
\end{aligned}$$

**8-132** A rigid tank containing nitrogen is considered. Nitrogen is allowed to escape until the mass of nitrogen becomes one-half of its initial mass. The change in the nitrogen's work potential is to be determined.

**Assumptions 1** This is an unsteady process since the conditions within the device are changing during the process. **2** Kinetic and potential energies are negligible. **3** There are no work interactions involved. **4** Nitrogen is an ideal gas with constant specific heats.

**Properties** The properties of nitrogen at room temperature are  $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 1.4$ , and  $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The initial and final masses in the tank are

$$m_1 = \frac{P_1 V}{RT_1} = \frac{(1000 \text{ kPa})(0.100 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 1.150 \text{ kg}$$

$$m_2 = m_e = \frac{m_1}{2} = \frac{1.150 \text{ kg}}{2} = 0.575 \text{ kg}$$

We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy  $h$  and internal energy  $u$ , respectively, the mass and energy balances for this uniform-flow system can be expressed as

*Mass balance:*

$$m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_2$$

*Energy balance:*

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$-m_e h_e = m_2 u_2 - m_1 u_1$$

Using the average of the initial and final temperatures for the exiting nitrogen, this energy balance equation becomes

$$\begin{aligned} -m_e h_e &= m_2 u_2 - m_1 u_1 \\ -m_e c_p T_e &= m_2 c_v T_2 - m_1 c_v T_1 \\ -(0.575)(1.039)(0.5)(293 + T_2) &= (0.575)(0.743)T_2 - (1.150)(0.743)(293) \end{aligned}$$

Solving for the final temperature, we get

$$T_2 = 224.3 \text{ K}$$

The final pressure in the tank is

$$P_2 = \frac{m_2 R T_2}{V} = \frac{(0.575 \text{ kg})(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(224.3 \text{ K})}{0.100 \text{ m}^3} = 382.8 \text{ kPa}$$

The average temperature and pressure for the exiting nitrogen is

$$T_e = 0.5(T_1 + T_2) = 0.5(293 + 224.3) = 258.7 \text{ K}$$

$$P_e = 0.5(T_1 + T_2) = 0.5(1000 + 382.8) = 691.4 \text{ kPa}$$

The work potential associated with this process is equal to the exergy destroyed during the process. The exergy destruction during a process can be determined from an exergy balance or directly from its

definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ . The entropy generation  $S_{\text{gen}}$  in this case is determined from an entropy balance on the system:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$-m_e s_e + S_{\text{gen}} = \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1$$

$$S_{\text{gen}} = m_2 s_2 - m_1 s_1 + m_e s_e$$

Rearranging and substituting gives

$$\begin{aligned} S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e \\ &= m_2 (c_p \ln T_2 - R \ln P_2) - m_1 (c_p \ln T_1 - R \ln P_1) + m_e (c_p \ln T_e - R \ln P_e) \\ &= (0.575)[1.039 \ln(224.3) - (0.2968) \ln(382.8)] - (1.15)[1.039 \ln(293) - (0.2968) \ln(1000)] \\ &\quad + (0.575)[1.039 \ln(258.7) - (0.2968) \ln(691.4)] \\ &= 2.2188 - 4.4292 + 2.2032 = -0.007152 \text{ kJ/K} \end{aligned}$$

Then,

$$W_{\text{rev}} = X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(-0.007152 \text{ kJ/K}) = \mathbf{-2.10 \text{ kJ}}$$

The entropy generation cannot be negative for a thermodynamically possible process. This result is probably due to using average temperature and pressure values for the exiting gas and using constant specific heats for nitrogen. This sensitivity occurs because the entropy generation is very small in this process.

### Alternative More Accurate Solution

This problem may also be solved by considering the variation of gas temperature and pressure at the outlet of the tank. The mass balance in this case is

$$\dot{m}_e = -\frac{dm}{dt}$$

which when combined with the reduced first law gives

$$\frac{d(mu)}{dt} = h \frac{dm}{dt}$$

Using the specific heats and the ideal gas equation of state reduces this to

$$c_v \frac{V}{R} \frac{dP}{dt} = c_p T \frac{dm}{dt}$$

which upon rearrangement and an additional use of ideal gas equation of state becomes

$$\frac{1}{P} \frac{dP}{dt} = \frac{c_p}{c_v} \frac{1}{m} \frac{dm}{dt}$$

When this is integrated, the result is

$$P_2 = P_1 \left( \frac{m_2}{m_1} \right)^k = 1000 \left( \frac{1}{2} \right)^{1.4} = 378.9 \text{ kPa}$$

The final temperature is then

$$T_2 = \frac{P_2 V}{m_2 R} = \frac{(378.9 \text{ kPa})(0.100 \text{ m}^3)}{(0.575 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 222.0 \text{ K}$$

The process is then one of

$$\frac{m^k}{P} = \text{const} \quad \text{or} \quad \frac{m^{k-1}}{T} = \text{const}$$

The reduced combined first and second law becomes

$$\dot{W}_{\text{rev}} = -\frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

when the mass balance is substituted and the entropy generation is set to zero (for maximum work production). Replacing the enthalpy term with the first law result and canceling the common  $dU/dt$  term reduces this to

$$\dot{W}_{\text{rev}} = T_0 \frac{d(ms)}{dt} - T_0 s \frac{dm}{dt}$$

Expanding the first derivative and canceling the common terms further reduces this to

$$\dot{W}_{\text{rev}} = T_0 m \frac{ds}{dt}$$

Letting  $a = P_1 / m_1^k$  and  $b = T_1 / m_1^{k-1}$ , the pressure and temperature of the nitrogen in the system are related to the mass by

$$P = am^k \quad \text{and} \quad T = bm^{k-1}$$

according to the first law. Then,

$$dP = akm^{k-1} dm \quad \text{and} \quad dT = b(k-1)m^{k-2} dm$$

The entropy change relation then becomes

$$ds = c_p \frac{dT}{T} - R \frac{dP}{P} = [(k-1)c_p - Rk] \frac{dm}{m}$$

Now, multiplying the combined first and second laws by  $dt$  and integrating the result gives

$$\begin{aligned} W_{\text{rev}} &= T_0 \int_1^2 m ds = T_0 \int_1^2 m ds [(k-1)c_p - Rk] \frac{dm}{m} \\ &= T_0 [(k-1)c_p - Rk] (m_2 - m_1) \\ &= (293) [(1.4-1)(1.039) - (0.2968)(1.4)] (0.575 - 1.15) \\ &= \mathbf{-0.0135 \text{ kJ}} \end{aligned}$$

Once again the entropy generation is negative, which cannot be the case for a thermodynamically possible process. This is probably due to using constant specific heats for nitrogen. This sensitivity occurs because the entropy generation is very small in this process.

**8-133** A system consisting of a compressor, a storage tank, and a turbine as shown in the figure is considered. The change in the exergy of the air in the tank and the work required to compress the air as the tank was being filled are to be determined.

**Assumptions** 1 Changes in the kinetic and potential energies are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ ,  $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$ ,  $k = 1.4$  (Table A-2a).

**Analysis** The initial mass of air in the tank is

$$m_{\text{initial}} = \frac{P_{\text{initial}} \mathcal{V}}{RT_{\text{initial}}} = \frac{(100 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 0.5946 \times 10^6 \text{ kg}$$

and the final mass in the tank is

$$m_{\text{final}} = \frac{P_{\text{final}} \mathcal{V}}{RT_{\text{final}}} = \frac{(600 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 3.568 \times 10^6 \text{ kg}$$

Since the compressor operates as an isentropic device,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k}$$

The conservation of mass applied to the tank gives

$$\frac{dm}{dt} = \dot{m}_{\text{in}}$$

while the first law gives

$$\dot{Q} = \frac{d(mu)}{dt} - h \frac{dm}{dt}$$

Employing the ideal gas equation of state and using constant specific heats, expands this result to

$$\dot{Q} = \frac{\mathcal{V} c_v}{R} \frac{dP}{dt} - c_p T_2 \frac{\mathcal{V}}{RT} \frac{dP}{dt}$$

Using the temperature relation across the compressor and multiplying by  $dt$  puts this result in the form

$$\dot{Q} dt = \frac{\mathcal{V} c_v}{R} dP - c_p T_1 \left( \frac{P}{P_1} \right)^{(k-1)/k} \frac{\mathcal{V}}{RT} dP$$

When this integrated, it yields ( $i$  and  $f$  stand for initial and final states)

$$\begin{aligned} Q &= \frac{\mathcal{V} c_v}{R} (P_f - P_i) - \frac{k}{2k-1} \frac{c_p \mathcal{V}}{R} \left[ P_f \left( \frac{P_f}{P_i} \right)^{(k-1)/k} - P_i \right] \\ &= \frac{(5 \times 10^5)(0.718)}{0.287} (600 - 100) - \frac{1.4}{2(1.4) - 1} \frac{(1.005)(5 \times 10^5)}{0.287} \left[ 600 \left( \frac{600}{100} \right)^{0.4/1.4} - 100 \right] \\ &= -6.017 \times 10^8 \text{ kJ} \end{aligned}$$

The negative result shows that heat is transferred from the tank. Applying the first law to the tank and compressor gives

$$(\dot{Q} - \dot{W}_{\text{out}})dt = d(mu) - h_1 dm$$

which integrates to

$$Q - W_{\text{out}} = (m_f u_f - m_i u_i) - h_1 (m_f - m_i)$$

Upon rearrangement,

$$\begin{aligned} W_{\text{out}} &= Q + (c_p - c_v)T(m_f - m_i) \\ &= -6.017 \times 10^8 + (1.005 - 0.718)(293)[(3.568 - 0.5946) \times 10^6] \\ &= \mathbf{-3.516 \times 10^8 \text{ kJ}} \end{aligned}$$

The negative sign shows that work is done on the compressor. When the combined first and second laws is reduced to fit the compressor and tank system and the mass balance incorporated, the result is

$$\dot{W}_{\text{rev}} = \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

which when integrated over the process becomes

$$\begin{aligned} W_{\text{rev}} &= Q \left( 1 - \frac{T_0}{T_R} \right) + m_i [(u_i - h_1) - T_0 (s_i - s_1)] - m_f [(u_f - h_1) - T_0 (s_f - s_1)] \\ &= -6.017 \times 10^8 \left( 1 - \frac{293}{293} \right) + 0.5946 \times 10^6 [(0.718 - 1.005)293] \\ &\quad - 3.568 \times 10^6 [(0.718 - 1.005)293] \left[ (0.718 - 1.005)293 + 293(0.287) \ln \frac{600}{100} \right] \\ &= \mathbf{-2.876 \times 10^8 \text{ kJ}} \end{aligned}$$

This is the exergy change of the air stored in the tank.

**8-134** The air stored in the tank of the system shown in the figure is released through the isentropic turbine. The work produced and the change in the exergy of the air in the tank are to be determined.

**Assumptions 1** Changes in the kinetic and potential energies are negligible. **4** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ ,  $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$ ,  $k = 1.4$  (Table A-2a).

**Analysis** The initial mass of air in the tank is

$$m_{\text{initial}} = \frac{P_{\text{initial}} \mathcal{V}}{RT_{\text{initial}}} = \frac{(600 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 3.568 \times 10^6 \text{ kg}$$

and the final mass in the tank is

$$m_{\text{final}} = \frac{P_{\text{final}} \mathcal{V}}{RT_{\text{final}}} = \frac{(100 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 0.5946 \times 10^6 \text{ kg}$$

The conservation of mass is

$$\frac{dm}{dt} = \dot{m}_{\text{in}}$$

while the first law gives

$$\dot{Q} = \frac{d(mu)}{dt} - h \frac{dm}{dt}$$

Employing the ideal gas equation of state and using constant specific heats, expands this result to

$$\begin{aligned} \dot{Q} &= \frac{\mathcal{V} c_v}{R} \frac{dP}{dt} - c_p T \frac{\mathcal{V}}{RT} \frac{dP}{dt} \\ &= \frac{c_v - c_p}{R} \mathcal{V} \frac{dP}{dt} \\ &= -\mathcal{V} \frac{dP}{dt} \end{aligned}$$

When this is integrated over the process, the result is ( $i$  and  $f$  stand for initial and final states)

$$Q = -\mathcal{V}(P_f - P_i) = -5 \times 10^5 (100 - 600) = 2.5 \times 10^8 \text{ kJ}$$

Applying the first law to the tank and compressor gives

$$(\dot{Q} - \dot{W}_{\text{out}})dt = d(mu) - hdm$$

which integrates to

$$\begin{aligned}
Q - W_{\text{out}} &= (m_f u_f - m_i u_i) + h(m_i - m_f) \\
-W_{\text{out}} &= -Q + m_f u_f - m_i u_i + h(m_i - m_f) \\
W_{\text{out}} &= Q - m_f u_f + m_i u_i - h(m_i - m_f) \\
&= Q - m_f c_v T + m_i c_p T - c_p T(m_i - m_f) \\
&= 2.5 \times 10^8 - (0.5946 \times 10^6)(0.718)(293) + (3.568 \times 10^6)(1.005)(293) \\
&\quad - (1.005)(293)(3.568 \times 10^6 - 0.5946 \times 10^6) \\
&= \mathbf{3.00 \times 10^8 \text{ kJ}}
\end{aligned}$$

This is the work output from the turbine. When the combined first and second laws is reduced to fit the turbine and tank system and the mass balance incorporated, the result is

$$\begin{aligned}
\dot{W}_{\text{rev}} &= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) - (u - T_0 s) \frac{dm}{dt} - m \frac{d(u - T_0 s)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T \frac{dm}{dt} + m T_0 \frac{ds}{dt} \\
&= \dot{Q} \left( 1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T \frac{dm}{dt} - \nu \frac{T_0}{T} (P_f - P_i)
\end{aligned}$$

where the last step uses entropy change equation. When this is integrated over the process it becomes

$$\begin{aligned}
W_{\text{rev}} &= Q \left( 1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T (m_f - m_i) - \nu \frac{T_0}{T} (P_f - P_i) \\
&= 3.00 \times 10^8 \left( 1 - \frac{293}{293} \right) + (1.005 - 0.718)(293)(0.5946 - 3.568) \times 10^6 - 5 \times 10^5 \frac{293}{293} (100 - 600) \\
&= 0 - 2.500 \times 10^8 - 2.5 \times 10^8 \\
&= \mathbf{-5.00 \times 10^8 \text{ kJ}}
\end{aligned}$$

This is the exergy change of the air in the storage tank.

**8-135** A heat engine operates between a tank and a cylinder filled with air at different temperatures. The maximum work that can be produced and the final temperatures are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The specific heats of air are  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$  and  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2).

**Analysis** For maximum power production, the entropy generation must be zero. We take the tank, the cylinder (the heat source and the heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} = \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} = \Delta S_{\text{tank,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}}$$

$$(\Delta S)_{\text{source}} + (\Delta S)_{\text{sink}} = 0$$

$$\left( m c_v \ln \frac{T_2}{T_{1A}} - m R \ln \frac{v_2}{v_1} \right)_{\text{source}} + 0 + \left( m c_p \ln \frac{T_2}{T_1} - m R \ln \frac{P_2}{P_1} \right)_{\text{sink}} = 0$$

$$\ln \frac{T_2}{T_{1A}} + \frac{c_p}{c_v} \ln \frac{T_2}{T_{1B}} = 0 \longrightarrow \frac{T_2}{T_{1A}} \left( \frac{T_2}{T_{1B}} \right)^k = 1 \longrightarrow T_2 = (T_{1A} T_{1B}^k)^{1/(k+1)}$$

where  $T_{1A}$  and  $T_{1B}$  are the initial temperatures of the source and the sink, respectively, and  $T_2$  is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = \left( (800 \text{ K})(290 \text{ K})^{1.4} \right)^{\frac{1}{2.4}} = \mathbf{442.6 \text{ K}}$$

*Source:*

$$-Q_{\text{source,out}} = \Delta U = m c_v (T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = m c_v (T_{1A} - T_2)$$

$$Q_{\text{source,out}} = m c_v (T_{1A} - T_2) = (20 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(800 - 442.6) \text{ K} = 5132 \text{ kJ}$$

*Sink:*

$$Q_{\text{sink,in}} - W_{\text{b,out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = m c_p (T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = m c_p (T_2 - T_{1A}) = (20 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(442.6 - 290) \text{ K} = 3068 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 5132 - 3068 = \mathbf{2064 \text{ kJ}}$$

Therefore, a maximum of 2064 kJ of work can be produced during this process.

**8-136** Using an incompressible substance as an example, it is to be demonstrated if closed system and flow exergies can be negative.

**Analysis** The availability of a closed system cannot be negative. However, the flow availability can be negative at low pressures. A closed system has zero availability at dead state, and positive availability at any other state since we can always produce work when there is a pressure or temperature differential.

To see that the flow availability can be negative, consider an incompressible substance. The flow availability can be written as

$$\begin{aligned}\psi &= h - h_0 + T_0(s - s_0) \\ &= (u - u_0) + v(P - P_0) + T_0(s - s_0) \\ &= \xi + v(P - P_0)\end{aligned}$$

The closed system availability  $\xi$  is always positive or zero, and the flow availability can be negative when  $P \ll P_0$ .

**8-137** A relation for the second-law efficiency of a heat engine operating between a heat source and a heat sink at specified temperatures is to be obtained.

**Analysis** The second-law efficiency is defined as the ratio of the availability recovered to availability supplied during a process. The work  $W$  produced is the availability recovered. The decrease in the availability of the heat supplied  $Q_H$  is the availability supplied or invested.

Therefore,

$$\eta_{II} = \frac{W}{\left(1 - \frac{T_0}{T_H}\right)Q_H - \left(1 - \frac{T_0}{T_L}\right)(Q_H - W)}$$

Note that the first term in the denominator is the availability of heat supplied to the heat engine whereas the second term is the availability of the heat rejected by the heat engine. The difference between the two is the availability consumed during the process.

**8-138E** Large brass plates are heated in an oven at a rate of 300/min. The rate of heat transfer to the plates in the oven and the rate of exergy destruction associated with this heat transfer process are to be determined.

**Assumptions** 1 The thermal properties of the plates are constant. 2 The changes in kinetic and potential energies are negligible. 3 The environment temperature is 75°F.

**Properties** The density and specific heat of the brass are given to be  $\rho = 532.5 \text{ lbm/ft}^3$  and  $c_p = 0.091 \text{ Btu/lbm} \cdot ^\circ\text{F}$ .

**Analysis** We take the plate to be the system. The energy balance for this closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} = \Delta U_{\text{plate}} = m(u_2 - u_1) = mc(T_2 - T_1)$$

The mass of each plate and the amount of heat transfer to each plate is

$$m = \rho V = \rho LA = (532.5 \text{ lbm/ft}^3)[(1.2 / 12 \text{ ft})(2 \text{ ft})(2 \text{ ft})] = 213 \text{ lbm}$$

$$Q_{\text{in}} = mc(T_2 - T_1) = (213 \text{ lbm/plate})(0.091 \text{ Btu/lbm} \cdot ^\circ\text{F})(1000 - 75)^\circ\text{F} = 17,930 \text{ Btu/plate}$$

Then the total rate of heat transfer to the plates becomes

$$\dot{Q}_{\text{total}} = \dot{n}_{\text{plate}} Q_{\text{in, per plate}} = (300 \text{ plates/min}) \times (17,930 \text{ Btu/plate}) = \mathbf{5,379,000 \text{ Btu/min} = 89,650 \text{ Btu/s}}$$

We again take a single plate as the system. The entropy generated during this process can be determined by applying an entropy balance on an *extended system* that includes the plate and its immediate surroundings so that the boundary temperature of the extended system is at 1300°F at all times:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\frac{Q_{\text{in}}}{T_b} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}}$$

where

$$\Delta S_{\text{system}} = m(s_2 - s_1) = mc_{\text{avg}} \ln \frac{T_2}{T_1} = (213 \text{ lbm})(0.091 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{(1000 + 460) \text{ R}}{(75 + 460) \text{ R}} = 19.46 \text{ Btu/R}$$

Substituting,

$$S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}} = -\frac{17,930 \text{ Btu}}{1300 + 460 \text{ R}} + 19.46 \text{ Btu/R} = 9.272 \text{ Btu/R (per plate)}$$

Then the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = S_{\text{gen}} \dot{n}_{\text{plate}} = (9.272 \text{ Btu/R} \cdot \text{plate})(300 \text{ plates/min}) = 2781 \text{ Btu/min} \cdot \text{R} = 46.35 \text{ Btu/s} \cdot \text{R}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (535 \text{ R})(46.35 \text{ Btu/s} \cdot \text{R}) = \mathbf{24,797 \text{ Btu/s}}$$

**8-139** Long cylindrical steel rods are heat-treated in an oven. The rate of heat transfer to the rods in the oven and the rate of exergy destruction associated with this heat transfer process are to be determined.

**Assumptions** **1** The thermal properties of the rods are constant. **2** The changes in kinetic and potential energies are negligible. **3** The environment temperature is 30°C.

**Properties** The density and specific heat of the steel rods are given to be  $\rho = 7833 \text{ kg/m}^3$  and  $c_p = 0.465 \text{ kJ/kg} \cdot ^\circ\text{C}$ .

**Analysis** Noting that the rods enter the oven at a velocity of 3 m/min and exit at the same velocity, we can say that a 3-m long section of the rod is heated in the oven in 1 min. Then the mass of the rod heated in 1 minute is

$$m = \rho V = \rho LA = \rho L(\pi D^2 / 4) = (7833 \text{ kg/m}^3)(3 \text{ m})[\pi(0.1 \text{ m})^2 / 4] = 184.6 \text{ kg}$$

We take the 3-m section of the rod in the oven as the system. The energy balance for this closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} = \Delta U_{\text{rod}} = m(u_2 - u_1) = mc(T_2 - T_1)$$

Substituting,

$$Q_{\text{in}} = mc(T_2 - T_1) = (184.6 \text{ kg})(0.465 \text{ kJ/kg} \cdot ^\circ\text{C})(700 - 30)^\circ\text{C} = 57,512 \text{ kJ}$$

Noting that this much heat is transferred in 1 min, the rate of heat transfer to the rod becomes

$$\dot{Q}_{\text{in}} = Q_{\text{in}} / \Delta t = (57,512 \text{ kJ}) / (1 \text{ min}) = 57,512 \text{ kJ/min} = \mathbf{958.5 \text{ kW}}$$

We again take the 3-m long section of the rod as the system. The entropy generated during this process can be determined by applying an entropy balance on an *extended system* that includes the rod and its immediate surroundings so that the boundary temperature of the extended system is at 900°C at all times:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\frac{Q_{\text{in}}}{T_b} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}}$$

where

$$\Delta S_{\text{system}} = m(s_2 - s_1) = mc_{\text{avg}} \ln \frac{T_2}{T_1} = (184.6 \text{ kg})(0.465 \text{ kJ/kg} \cdot \text{K}) \ln \frac{700 + 273}{30 + 273} = 100.1 \text{ kJ/K}$$

Substituting,

$$S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}} = -\frac{57,512 \text{ kJ}}{(900 + 273) \text{ K}} + 100.1 \text{ kJ/K} = 51.1 \text{ kJ/K}$$

Noting that this much entropy is generated in 1 min, the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = \frac{S_{\text{gen}}}{\Delta t} = \frac{51.1 \text{ kJ/K}}{1 \text{ min}} = 51.1 \text{ kJ/min} \cdot \text{K} = 0.852 \text{ kW/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(0.852 \text{ kW/K}) = \mathbf{254 \text{ kW}}$$

**8-140** Steam is condensed by cooling water in the condenser of a power plant. The rate of condensation of steam and the rate of exergy destruction are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. 3 Changes in the kinetic and potential energies of fluid streams are negligible. 4 Fluid properties are constant.

**Properties** The enthalpy and entropy of vaporization of water at 60°C are  $h_{fg}=2357.7$  kJ/kg and  $s_{fg}=7.0769$  kJ/kg.K (Table A-4). The specific heat of water at room temperature is  $c_p=4.18$  kJ/kg.°C (Table A-3).

**Analysis** (a) We take the cold water tubes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{in} - \dot{E}_{out}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{system}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \overset{\approx 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta ke \cong \Delta pe \cong 0)$$

$$\dot{Q}_{in} = \dot{m}C_p(T_2 - T_1)$$

Then the heat transfer rate to the cooling water in the condenser becomes

$$\begin{aligned} \dot{Q} &= [\dot{m}C_p(T_{out} - T_{in})]_{\text{cooling water}} \\ &= (140 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C} - 15^\circ\text{C}) = 5852 \text{ kJ/s} \end{aligned}$$

The rate of condensation of steam is determined to be

$$\dot{Q} = (\dot{m}h_{fg})_{\text{steam}} \longrightarrow \dot{m}_{\text{steam}} = \frac{\dot{Q}}{h_{fg}} = \frac{5852 \text{ kJ/s}}{2357.7 \text{ kJ/kg}} = \mathbf{2.482 \text{ kg/s}}$$

(b) The rate of entropy generation within the condenser during this process can be determined by applying the rate form of the entropy balance on the entire condenser. Noting that the condenser is well-insulated and thus heat transfer is negligible, the entropy balance for this steady-flow system can be expressed as

$$\underbrace{\dot{S}_{in} - \dot{S}_{out}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{gen}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{system}}_{\text{Rate of change of entropy}} \overset{\approx 0 \text{ (steady)}}{=}$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{gen} = 0 \quad (\text{since } \dot{Q} = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{steam}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{steam}} s_4 + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{steam}}(s_4 - s_3)$$

Noting that water is an incompressible substance and steam changes from saturated vapor to saturated liquid, the rate of entropy generation is determined to be

$$\begin{aligned} \dot{S}_{gen} &= \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{steam}}(s_f - s_g) = \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} - \dot{m}_{\text{steam}} s_{fg} \\ &= (140 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{25 + 273}{15 + 273} - (2.482 \text{ kg/s})(7.0769 \text{ kJ/kg} \cdot \text{K}) = 2.409 \text{ kW/K} \end{aligned}$$

Then the exergy destroyed can be determined directly from its definition  $X_{\text{destroyed}} = T_0 \dot{S}_{gen}$  to be

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{gen} = (288 \text{ K})(2.409 \text{ kW/K}) = \mathbf{694 \text{ kW}}$$

**8-141** Water is heated in a heat exchanger by geothermal water. The rate of heat transfer to the water and the rate of exergy destruction within the heat exchanger are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. 3 Changes in the kinetic and potential energies of fluid streams are negligible. 4 Fluid properties are constant. 5 The environment temperature is 25°C.

**Properties** The specific heats of water and geothermal fluid are given to be 4.18 and 4.31 kJ/kg·°C, respectively.

**Analysis** (a) We take the cold water tubes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

$$\dot{Q}_{\text{in}} = \dot{m}c_p(T_2 - T_1)$$

Then the rate of heat transfer to the cold water in the heat exchanger becomes

$$\dot{Q}_{\text{in, water}} = [\dot{m}c_p(T_{\text{out}} - T_{\text{in}})]_{\text{water}} = (0.4 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(60^\circ\text{C} - 25^\circ\text{C}) = \mathbf{58.52 \text{ kW}}$$

Noting that heat transfer to the cold water is equal to the heat loss from the geothermal water, the outlet temperature of the geothermal water is determined from

$$\dot{Q}_{\text{out}} = [\dot{m}c_p(T_{\text{in}} - T_{\text{out}})]_{\text{geo}} \longrightarrow T_{\text{out}} = T_{\text{in}} - \frac{\dot{Q}_{\text{out}}}{\dot{m}c_p} = 140^\circ\text{C} - \frac{58.52 \text{ kW}}{(0.3 \text{ kg/s})(4.31 \text{ kJ/kg} \cdot ^\circ\text{C})} = 94.7^\circ\text{C}$$

(b) The rate of entropy generation within the heat exchanger is determined by applying the rate form of the entropy balance on the entire heat exchanger:

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{\text{gen}} = 0 \quad (\text{since } \dot{Q} = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{geo}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{geo}} s_4 + \dot{S}_{\text{gen}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{geo}}(s_4 - s_3)$$

Noting that both fresh and geothermal water are incompressible substances, the rate of entropy generation is determined to be

$$\dot{S}_{\text{gen}} = \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{geo}} c_p \ln \frac{T_4}{T_3}$$

$$= (0.4 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{60 + 273}{25 + 273} + (0.3 \text{ kg/s})(4.31 \text{ kJ/kg} \cdot \text{K}) \ln \frac{94.7 + 273}{140 + 273} = 0.0356 \text{ kW/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$ ,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(0.0356 \text{ kW/K}) = \mathbf{10.61 \text{ kW}}$$

**8-142** A regenerator is considered to save heat during the cooling of milk in a dairy plant. The amounts of fuel and money such a generator will save per year and the rate of exergy destruction within the regenerator are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The properties of the milk are constant. 5 The environment temperature is 18°C.

**Properties** The average density and specific heat of milk can be taken to be  $\rho_{\text{milk}} \cong \rho_{\text{water}} = 1 \text{ kg/L}$  and  $c_{p,\text{milk}} = 3.79 \text{ kJ/kg} \cdot ^\circ\text{C}$  (Table A-3).

**Analysis** The mass flow rate of the milk is

$$\dot{m}_{\text{milk}} = \rho \dot{V}_{\text{milk}} = (1 \text{ kg/L})(12 \text{ L/s}) = 12 \text{ kg/s} = 43,200 \text{ kg/h}$$

Taking the pasteurizing section as the system, the energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \overset{\text{no (steady)}}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{milk}} c_p (T_2 - T_1)$$

Therefore, to heat the milk from 4 to 72°C as being done currently, heat must be transferred to the milk at a rate of

$$\dot{Q}_{\text{current}} = [\dot{m} c_p (T_{\text{pasteurization}} - T_{\text{refrigeration}})]_{\text{milk}} = (12 \text{ kg/s})(3.79 \text{ kJ/kg} \cdot ^\circ\text{C})(72 - 4)^\circ\text{C} = 3093 \text{ kJ/s}$$

The proposed regenerator has an effectiveness of  $\varepsilon = 0.82$ , and thus it will save 82 percent of this energy. Therefore,

$$\dot{Q}_{\text{saved}} = \varepsilon \dot{Q}_{\text{current}} = (0.82)(3093 \text{ kJ/s}) = 2536 \text{ kJ/s}$$

Noting that the boiler has an efficiency of  $\eta_{\text{boiler}} = 0.82$ , the energy savings above correspond to fuel savings of

$$\text{Fuel Saved} = \frac{\dot{Q}_{\text{saved}}}{\eta_{\text{boiler}}} = \frac{(2536 \text{ kJ/s})}{(0.82)} \frac{(1 \text{ therm})}{(105,500 \text{ kJ})} = 0.02931 \text{ therm/s}$$

Noting that 1 year = 365×24=8760 h and unit cost of natural gas is \$1.04/therm, the annual fuel and money savings will be

$$\text{Fuel Saved} = (0.02931 \text{ therms/s})(8760 \times 3600 \text{ s}) = \mathbf{924,450 \text{ therms/yr}}$$

$$\text{Money saved} = (\text{Fuel saved})(\text{Unit cost of fuel}) = (924,450 \text{ therm/yr})(\$1.04/\text{therm}) = \mathbf{\$961,430/\text{yr}}$$

The rate of entropy generation during this process is determined by applying the rate form of the entropy balance on an *extended system* that includes the regenerator and the immediate surroundings so that the boundary temperature is the surroundings temperature, which we take to be the cold water temperature of 18°C.:

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \overset{\text{no (steady)}}{=} 0 \rightarrow \dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

Disregarding entropy transfer associated with fuel flow, the only significant difference between the two cases is the reduction in the entropy transfer to water due to the reduction in heat transfer to water, and is determined to be

$$\dot{S}_{\text{gen, reduction}} = \dot{S}_{\text{out, reduction}} = \frac{\dot{Q}_{\text{out, reduction}}}{T_{\text{surr}}} = \frac{\dot{Q}_{\text{saved}}}{T_{\text{surr}}} = \frac{2536 \text{ kJ/s}}{18 + 273} = 8.715 \text{ kW/K}$$

$$S_{\text{gen, reduction}} = \dot{S}_{\text{gen, reduction}} \Delta t = (8.715 \text{ kJ/s} \cdot \text{K})(8760 \times 3600 \text{ s/year}) = 2.75 \times 10^8 \text{ kJ/K (per year)}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ ,

$$X_{\text{destroyed, reduction}} = T_0 S_{\text{gen, reduction}} = (291 \text{ K})(2.75 \times 10^8 \text{ kJ/K}) = \mathbf{8.00 \times 10^{10} \text{ kJ (per year)}}$$

**8-143** Exhaust gases are expanded in a turbine, which is not well-insulated. The actual and reversible power outputs, the exergy destroyed, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and the specific heat of air at the average temperature of  $(750+630)/2 = 690^\circ\text{C}$  is  $c_p = 1.134 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-2).

**Analysis** (a) The enthalpy and entropy changes of air across the turbine are

$$\Delta h = c_p (T_1 - T_2) = (1.134 \text{ kJ/kg}\cdot^\circ\text{C})(750 - 630)^\circ\text{C} = 136.08 \text{ kJ/kg}$$

$$\begin{aligned} \Delta s &= c_p \ln \frac{T_1}{T_2} - R \ln \frac{P_1}{P_2} \\ &= (1.134 \text{ kJ/kg}\cdot\text{K}) \ln \frac{(750 + 273) \text{ K}}{(630 + 273) \text{ K}} - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{1200 \text{ kPa}}{500 \text{ kPa}} \\ &= -0.005354 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

The actual and reversible power outputs from the turbine are

$$\dot{W}_a = \dot{m}\Delta h - \dot{Q}_{\text{out}} = (3.4 \text{ kg/s})(136.08 \text{ kJ/kg}) - 30 \text{ kW} = \mathbf{432.7 \text{ kW}}$$

$$\dot{W}_{\text{rev}} = \dot{m}(\Delta h - T_0 \Delta s) = (3.4 \text{ kg/s})(136.08 \text{ kJ/kg}) - (25 + 273 \text{ K})(-0.005354 \text{ kJ/kg}\cdot\text{K}) = \mathbf{516.9 \text{ kW}}$$

(b) The exergy destroyed in the turbine is

$$\dot{X}_{\text{dest}} = \dot{W}_{\text{rev}} - \dot{W}_a = 516.9 - 432.7 = \mathbf{84.2 \text{ kW}}$$

(c) The second-law efficiency is

$$\eta_{\text{II}} = \frac{\dot{W}_a}{\dot{W}_{\text{rev}}} = \frac{432.7 \text{ kW}}{516.9 \text{ kW}} = \mathbf{0.837}$$

**8-144** Refrigerant-134a is compressed in an adiabatic compressor, whose second-law efficiency is given. The actual work input, the isentropic efficiency, and the exergy destruction are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The properties of the refrigerant at the inlet of the compressor are (Tables A-11 through A-13)

$$T_{\text{sat}@160 \text{ kPa}} = -15.60^\circ\text{C}$$

$$\left. \begin{array}{l} P_1 = 160 \text{ kPa} \\ T_1 = (-15.60 + 3)^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 243.60 \text{ kJ/kg} \\ s_1 = 0.95153 \text{ kJ/kg}\cdot\text{K} \end{array}$$

The enthalpy at the exit for if the process was isentropic is

$$\left. \begin{array}{l} P_2 = 1 \text{ MPa} \\ s_2 = s_1 = 0.95153 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{2s} = 282.41 \text{ kJ/kg}$$

The expressions for actual and reversible works are

$$w_a = h_2 - h_1 = (h_2 - 243.60) \text{ kJ/kg}$$

$$w_{\text{rev}} = h_2 - h_1 - T_0(s_2 - s_1) = (h_2 - 243.60) \text{ kJ/kg} - (25 + 273 \text{ K})(s_2 - 0.95153) \text{ kJ/kg}\cdot\text{K}$$

Substituting these into the expression for the second-law efficiency

$$\eta_{\text{II}} = \frac{w_{\text{rev}}}{w_a} \longrightarrow 0.80 = \frac{h_2 - 243.60 - (298)(s_2 - 0.95153)}{h_2 - 243.60}$$

The exit pressure is given (1 MPa). We need one more property to fix the exit state. By a trial-error approach or using EES, we obtain the exit temperature to be  $60^\circ\text{C}$ . The corresponding enthalpy and entropy values satisfying this equation are

$$h_2 = 293.36 \text{ kJ/kg}$$

$$s_2 = 0.98492 \text{ kJ/kg}\cdot\text{K}$$

Then,

$$w_a = h_2 - h_1 = 293.36 - 243.60 = \mathbf{49.76 \text{ kJ/kg}}$$

$$w_{\text{rev}} = h_2 - h_1 - T_0(s_2 - s_1) = (293.36 - 243.60) \text{ kJ/kg} - (25 + 273 \text{ K})(0.98492 - 0.9515) \text{ kJ/kg}\cdot\text{K} = 39.81 \text{ kJ/kg}$$

(b) The isentropic efficiency is determined from its definition

$$\eta_s = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{(282.41 - 243.60) \text{ kJ/kg}}{(293.36 - 243.60) \text{ kJ/kg}} = \mathbf{0.780}$$

(b) The exergy destroyed in the compressor is

$$x_{\text{dest}} = w_a - w_{\text{rev}} = 49.76 - 39.81 = \mathbf{9.95 \text{ kJ/kg}}$$

**8-145** The isentropic efficiency of a water pump is specified. The actual power output, the rate of frictional heating, the exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Using saturated liquid properties at the given temperature for the inlet state (Table A-4)

$$\left. \begin{array}{l} T_1 = 30^\circ\text{C} \\ x_1 = 0 \end{array} \right\} \begin{array}{l} h_1 = 125.82 \text{ kJ/kg} \\ s_1 = 0.4367 \text{ kJ/kg}\cdot\text{K} \\ \nu_1 = 0.001004 \text{ m}^3/\text{kg} \end{array}$$

The power input if the process was isentropic is

$$\dot{W}_s = \dot{m} \nu_1 (P_2 - P_1) = (1.35 \text{ kg/s})(0.001004 \text{ m}^3/\text{kg})(4000 - 100) \text{ kPa} = 5.288 \text{ kW}$$

Given the isentropic efficiency, the actual power may be determined to be

$$\dot{W}_a = \frac{\dot{W}_s}{\eta_s} = \frac{5.288 \text{ kW}}{0.70} = \mathbf{7.554 \text{ kW}}$$

(b) The difference between the actual and isentropic works is the frictional heating in the pump

$$\dot{Q}_{\text{frictional}} = \dot{W}_a - \dot{W}_s = 7.554 - 5.288 = \mathbf{2.266 \text{ kW}}$$

(c) The enthalpy at the exit of the pump for the actual process can be determined from

$$\dot{W}_a = \dot{m}(h_2 - h_1) \longrightarrow 7.554 \text{ kW} = (1.35 \text{ kg/s})(h_2 - 125.82) \text{ kJ/kg} \longrightarrow h_2 = 131.42 \text{ kJ/kg}$$

The entropy at the exit is

$$\left. \begin{array}{l} P_2 = 4 \text{ MPa} \\ h_2 = 131.42 \text{ kJ/kg} \end{array} \right\} s_2 = 0.4423 \text{ kJ/kg}\cdot\text{K}$$

The reversible power and the exergy destruction are

$$\begin{aligned} \dot{W}_{\text{rev}} &= \dot{m}[h_2 - h_1 - T_0(s_2 - s_1)] \\ &= (1.35 \text{ kg/s})[(131.42 - 125.82) \text{ kJ/kg} - (20 + 273 \text{ K})(0.4423 - 0.4367) \text{ kJ/kg}\cdot\text{K}] = 5.362 \text{ kW} \end{aligned}$$

$$\dot{X}_{\text{dest}} = \dot{W}_a - \dot{W}_{\text{rev}} = 7.554 - 5.362 = \mathbf{2.193 \text{ kW}}$$

(d) The second-law efficiency is

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_a} = \frac{5.362 \text{ kW}}{7.554 \text{ kW}} = \mathbf{0.710}$$

**8-146** Argon gas is expanded adiabatically in an expansion valve. The exergy of argon at the inlet, the exergy destruction, and the second-law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are zero. 3 Argon is an ideal gas with constant specific heats.

**Properties** The properties of argon gas are  $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 0.5203 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-2).

**Analysis** (a) The exergy of the argon at the inlet is

$$\begin{aligned}
 x_1 &= h_1 - h_0 - T_0(s_1 - s_0) \\
 &= c_p(T_1 - T_0) - T_0 \left[ c_p \ln \frac{T_1}{T_0} - R \ln \frac{P_1}{P_0} \right] \\
 &= (0.5203 \text{ kJ/kg}\cdot\text{K})(100 - 25)^\circ\text{C} - (298 \text{ K}) \left[ (0.5203 \text{ kJ/kg}\cdot\text{K}) \ln \frac{373 \text{ K}}{298 \text{ K}} - (0.2081 \text{ kJ/kg}\cdot\text{K}) \ln \frac{3500 \text{ kPa}}{100 \text{ kPa}} \right] \\
 &= \mathbf{224.7 \text{ kJ/kg}}
 \end{aligned}$$

(b) Noting that the temperature remains constant in a throttling process, the exergy destruction is determined from

$$\begin{aligned}
 x_{\text{dest}} &= T_0 s_{\text{gen}} \\
 &= T_0(s_2 - s_1) \\
 &= T_0 \left( -R \ln \frac{P_1}{P_0} \right) = (298 \text{ K}) \left[ - (0.2081 \text{ kJ/kg}\cdot\text{K}) \ln \left( \frac{500 \text{ kPa}}{3500 \text{ kPa}} \right) \right] \\
 &= \mathbf{120.7 \text{ kJ/kg}}
 \end{aligned}$$

(c) The second-law efficiency is

$$\eta_{\text{II}} = \frac{x_1 - x_{\text{dest}}}{x_1} = \frac{(224.7 - 120.7) \text{ kJ/kg}}{224.7 \text{ kJ/kg}} = \mathbf{0.463}$$

**8-147** Heat is lost from the air flowing in a diffuser. The exit temperature, the rate of exergy destruction, and the second law efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Nitrogen is an ideal gas with variable specific heats.

**Properties** The gas constant of nitrogen is  $R = 0.2968 \text{ kJ/kg} \cdot \text{K}$ .

**Analysis** (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure. At the inlet of the diffuser and at the dead state, we have

$$\left. \begin{array}{l} T_1 = 15^\circ\text{C} = 423 \text{ K} \\ P_1 = 100 \text{ kPa} \end{array} \right\} \begin{array}{l} h_1 = 130.08 \text{ kJ/kg} \\ s_1 = 7.2006 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} T_1 = 300 \text{ K} \\ P_1 = 100 \text{ kPa} \end{array} \right\} \begin{array}{l} h_0 = 1.93 \text{ kJ/kg} \\ s_0 = 6.8426 \text{ kJ/kg} \cdot \text{K} \end{array}$$

An energy balance on the diffuser gives

$$\begin{aligned} h_1 + \frac{V_1^2}{2} &= h_2 + \frac{V_2^2}{2} + q_{\text{out}} \\ 130.08 \text{ kJ/kg} + \frac{(180 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) &= h_2 + \frac{(25 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) + 4.5 \text{ kJ/kg} \\ \longrightarrow h_2 &= 141.47 \text{ kJ/kg} \end{aligned}$$

The corresponding properties at the exit of the diffuser are

$$\left. \begin{array}{l} h_2 = 141.47 \text{ kJ/kg} \\ P_2 = 110 \text{ kPa} \end{array} \right\} \begin{array}{l} T_2 = \mathbf{160.9^\circ\text{C}} = 433.9 \text{ K} \\ s_2 = 7.1989 \text{ kJ/kg} \cdot \text{K} \end{array}$$

(b) The mass flow rate of the nitrogen is determined to be

$$\dot{m} = \rho_2 A_2 V_2 = \frac{P_2}{RT_2} A_2 V_2 = \frac{110 \text{ kPa}}{(0.2968 \text{ kJ/kg} \cdot \text{K})(433.9 \text{ K})} (0.06 \text{ m}^2)(25 \text{ m/s}) = 1.281 \text{ kg/s}$$

The exergy destruction in the nozzle is the exergy difference between the inlet and exit of the diffuser

$$\begin{aligned} \dot{X}_{\text{dest}} &= \dot{m} \left[ h_1 - h_2 + \frac{V_1^2 - V_2^2}{2} - T_0 (s_1 - s_2) \right] \\ &= (1.281 \text{ kg/s}) \left[ (130.08 - 141.47) \text{ kJ/kg} + \frac{(180 \text{ m/s})^2 - (25 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right. \\ &\quad \left. - (300 \text{ K})(7.2006 - 7.1989) \text{ kJ/kg} \cdot \text{K} \right] = \mathbf{5.11 \text{ kW}} \end{aligned}$$

(c) The second-law efficiency for this device may be defined as the exergy output divided by the exergy input:

$$\begin{aligned} \dot{X}_1 &= \dot{m} \left[ h_1 - h_0 + \frac{V_1^2}{2} - T_0 (s_1 - s_0) \right] \\ &= (1.281 \text{ kg/s}) \left[ (130.08 - 1.93) \text{ kJ/kg} + \frac{(180 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) - (300 \text{ K})(7.2006 - 6.8426) \text{ kJ/kg} \cdot \text{K} \right] \\ &= 47.35 \text{ kW} \\ \eta_{\text{II}} &= \frac{\dot{X}_2}{\dot{X}_1} = 1 - \frac{\dot{X}_{\text{dest}}}{\dot{X}_1} = 1 - \frac{5.11 \text{ kW}}{47.35 \text{ kW}} = \mathbf{0.892} \end{aligned}$$

## Fundamentals of Engineering (FE) Exam Problems

**8-148** Heat is lost through a plane wall steadily at a rate of 800 W. If the inner and outer surface temperatures of the wall are 20°C and 5°C, respectively, and the environment temperature is 0°C, the rate of exergy destruction within the wall is

- (a) 40 W                      (b) 17,500 W                      (c) 765 W                      (d) 32,800 W                      (e) 0 W

*Answer* (a) 40 W

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Q=800 "W"
T1=20 "C"
T2=5 "C"
To=0 "C"
"Entropy balance S_in - S_out + S_gen= DS_system for the wall for steady operation gives"
Q/(T1+273)-Q/(T2+273)+S_gen=0 "W/K"
X_dest=(To+273)*S_gen "W"
```

"Some Wrong Solutions with Common Mistakes:"

```
Q/T1-Q/T2+Sgen1=0; W1_Xdest=(To+273)*Sgen1 "Using C instead of K in Sgen"
Sgen2=Q/((T1+T2)/2); W2_Xdest=(To+273)*Sgen2 "Using avegage temperature in C for Sgen"
Sgen3=Q/((T1+T2)/2+273); W3_Xdest=(To+273)*Sgen3 "Using avegage temperature in K"
W4_Xdest=To*S_gen "Using C for To"
```

**8-149** Liquid water enters an adiabatic piping system at 15°C at a rate of 5 kg/s. It is observed that the water temperature rises by 0.5°C in the pipe due to friction. If the environment temperature is also 15°C, the rate of exergy destruction in the pipe is

- (a) 8.36 kW                      (b) 10.4 kW                      (c) 197 kW                      (d) 265 kW                      (e) 2410 kW

*Answer* (b) 10.4 kW

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Cp=4.18 "kJ/kg.K"
m=5 "kg/s"
T1=15 "C"
T2=15.5 "C"
To=15 "C"
S_gen=m*Cp*ln((T2+273)/(T1+273)) "kW/K"
X_dest=(To+273)*S_gen "kW"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Xdest=(To+273)*m*Cp*ln(T2/T1) "Using deg. C in Sgen"
W2_Xdest=To*m*Cp*ln(T2/T1) "Using deg. C in Sgen and To"
W3_Xdest=(To+273)*Cp*ln(T2/T1) "Not using mass flow rate with deg. C"
W4_Xdest=(To+273)*Cp*ln((T2+273)/(T1+273)) "Not using mass flow rate with K"
```

**8-150** A heat engine receives heat from a source at 1500 K at a rate of 600 kJ/s and rejects the waste heat to a sink at 300 K. If the power output of the engine is 400 kW, the second-law efficiency of this heat engine is

- (a) 42%                      (b) 53%                      (c) 83%                      (d) 67%                      (e) 80%

*Answer* (c) 83%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Qin=600 "kJ/s"
W=400 "kW"
TL=300 "K"
TH=1500 "K"
Eta_rev=1-TL/TH
Eta_th=W/Qin
Eta_II=Eta_th/Eta_rev
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta_II=Eta_th1/Eta_rev; Eta_th1=1-W/Qin "Using wrong relation for thermal efficiency"
W2_Eta_II=Eta_th "Taking second-law efficiency to be thermal efficiency"
W3_Eta_II=Eta_rev "Taking second-law efficiency to be reversible efficiency"
W4_Eta_II=Eta_th*Eta_rev "Multiplying thermal and reversible efficiencies instead of dividing"
```

**8-151** A water reservoir contains 100 tons of water at an average elevation of 60 m. The maximum amount of electric power that can be generated from this water is

- (a) 8 kWh                      (b) 16 kWh                      (c) 1630 kWh                      (d) 16,300 kWh                      (e) 58,800 kWh

*Answer* (b) 16 kWh

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
m=100000 "kg"
h=60 "m"
g=9.81 "m/s^2"
"Maximum power is simply the potential energy change,"
W_max=m*g*h/1000 "kJ"
W_max_kWh=W_max/3600 "kWh"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Wmax =m*g*h/3600 "Not using the conversion factor 1000"
W2_Wmax =m*g*h/1000 "Obtaining the result in kJ instead of kWh"
W3_Wmax =m*g*h*3.6/1000 "Using wrong conversion factor"
W4_Wmax =m*h/3600 "Not using g and the factor 1000 in calculations"
```

**8-152** A house is maintained at 25°C in winter by electric resistance heaters. If the outdoor temperature is 2°C, the second-law efficiency of the resistance heaters is

- (a) 0%                      (b) 7.7%                      (c) 8.7%                      (d) 13%                      (e) 100%

*Answer* (b) 7.7%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
TL=2+273 "K"
TH=25+273 "K"
To=TL
COP_rev=TH/(TH-TL)
COP=1
Eta_II=COP/COP_rev
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta_II=COP/COP_rev1; COP_rev1=TL/(TH-TL) "Using wrong relation for COP_rev"
W2_Eta_II=1-(TL-273)/(TH-273) "Taking second-law efficiency to be reversible thermal efficiency with C for temp"
W3_Eta_II=COP_rev "Taking second-law efficiency to be reversible COP"
W4_Eta_II=COP_rev2/COP; COP_rev2=(TL-273)/(TH-TL) "Using C in COP_rev relation instead of K, and reversing"
```

**8-153** A 10-kg solid whose specific heat is 2.8 kJ/kg.°C is at a uniform temperature of -10°C. For an environment temperature of 25°C, the exergy content of this solid is

- (a) Less than zero      (b) 0 kJ      (c) 22.3 kJ      (d) 62.5 kJ      (e) 980 kJ

*Answer* (d) 62.5 kJ

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
m=10 "kg"
Cp=2.8 "kJ/kg.K"
T1=-10+273 "K"
To=25+273 "K"
"Exergy content of a fixed mass is x1=u1-u0-To*(s1-s0)+Po*(v1-v0)"
ex=m*(Cp*(T1-To)-To*Cp*ln(T1/To))
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_ex=m*Cp*(To-T1) "Taking the energy content as the exergy content"
W2_ex=m*(Cp*(T1-To)+To*Cp*ln(T1/To)) "Using + for the second term instead of -"
W3_ex=Cp*(T1-To)-To*Cp*ln(T1/To) "Using exergy content per unit mass"
W4_ex=0 "Taking the exergy content to be zero"
```

**8-154** Keeping the limitations imposed by the second-law of thermodynamics in mind, choose the wrong statement below:

- (a) A heat engine cannot have a thermal efficiency of 100%.  
 (b) For all reversible processes, the second-law efficiency is 100%.  
 (c) The second-law efficiency of a heat engine cannot be greater than its thermal efficiency.  
 (d) The second-law efficiency of a process is 100% if no entropy is generated during that process.  
 (e) The coefficient of performance of a refrigerator can be greater than 1.

*Answer* (c) The second-law efficiency of a heat engine cannot be greater than its thermal efficiency.

**8-155** A furnace can supply heat steadily at a 1600 K at a rate of 800 kJ/s. The maximum amount of power that can be produced by using the heat supplied by this furnace in an environment at 300 K is

- (a) 150 kW                      (b) 210 kW                      (c) 325 kW                      (d) 650 kW                      (e) 984 kW

*Answer* (d) 650 kW

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Q_in=800 "kJ/s"
TL=300 "K"
TH=1600 "K"
W_max=Q_in*(1-TL/TH) "kW"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Wmax=W_max/2 "Taking half of Wmax"
W2_Wmax=Q_in/(1-TL/TH) "Dividing by efficiency instead of multiplying by it"
W3_Wmax =Q_in*TL/TH "Using wrong relation"
W4_Wmax=Q_in "Assuming entire heat input is converted to work"
```

**8-156** Air is throttled from 50°C and 800 kPa to a pressure of 200 kPa at a rate of 0.5 kg/s in an environment at 25°C. The change in kinetic energy is negligible, and no heat transfer occurs during the process. The power potential wasted during this process is

- (a) 0                              (b) 0.20 kW                      (c) 47 kW                      (d) 59 kW                      (e) 119 kW

*Answer* (d) 59 kW

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
R=0.287 "kJ/kg.K"

-W3_Dx=h2-h1-To*(s2-s1) "Using C for To instead of K"
-W4_Dx=(h2+(T2+273)*s2)-(h1+(T1+273)*s1) "Using wrong relations for exergy"
```

## 8- 158 ... 8- 162 Design and Essay Problems

## Chapter 9

# GAS POWER CYCLES

### Actual and Ideal Cycles, Carnot cycle, Air-Standard Assumptions

**9-1C** The Carnot cycle is not suitable as an ideal cycle for all power producing devices because it cannot be approximated using the hardware of actual power producing devices.

**9-2C** It is less than the thermal efficiency of a Carnot cycle.

**9-3C** It represents the net work on both diagrams.

**9-4C** The cold air standard assumptions involves the additional assumption that air can be treated as an ideal gas with constant specific heats at room temperature.

**9-5C** Under the air standard assumptions, the combustion process is modeled as a heat addition process, and the exhaust process as a heat rejection process.

**9-6C** The air standard assumptions are: (1) the working fluid is air which behaves as an ideal gas, (2) all the processes are internally reversible, (3) the combustion process is replaced by the heat addition process, and (4) the exhaust process is replaced by the heat rejection process which returns the working fluid to its original state.

**9-7C** The clearance volume is the minimum volume formed in the cylinder whereas the displacement volume is the volume displaced by the piston as the piston moves between the top dead center and the bottom dead center.

**9-8C** It is the ratio of the maximum to minimum volumes in the cylinder.

**9-9C** The MEP is the fictitious pressure which, if acted on the piston during the entire power stroke, would produce the same amount of net work as that produced during the actual cycle.

**9-10C** Yes.

**9-11C** Assuming no accumulation of carbon deposits on the piston face, the compression ratio will remain the same (otherwise it will increase). The mean effective pressure, on the other hand, will decrease as a car gets older as a result of wear and tear.

**9-12C** The SI and CI engines differ from each other in the way combustion is initiated; by a spark in SI engines, and by compressing the air above the self-ignition temperature of the fuel in CI engines.

**9-13C** Stroke is the distance between the TDC and the BDC, bore is the diameter of the cylinder, TDC is the position of the piston when it forms the smallest volume in the cylinder, and clearance volume is the minimum volume formed in the cylinder.

**9-14** The temperatures of the energy reservoirs of an ideal gas power cycle are given. It is to be determined if this cycle can have a thermal efficiency greater than 55 percent.

**Analysis** The maximum efficiency any engine using the specified reservoirs can have is

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{(17 + 273) \text{ K}}{(627 + 273) \text{ K}} = \mathbf{0.678}$$

Therefore, an efficiency of 55 percent is possible.

**9-15** The four processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $\nu$  and  $T$ - $s$  diagrams, and the net work output and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis** (b) The properties of air at various states are

$$T_1 = 300\text{ K} \longrightarrow \begin{aligned} h_1 &= 300.19 \text{ kJ/kg} \\ P_{r_1} &= 1.386 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \frac{800 \text{ kPa}}{100 \text{ kPa}} (1.386) = 11.088 \longrightarrow \begin{aligned} u_2 &= 389.22 \text{ kJ/kg} \\ T_2 &= 539.8 \text{ K} \end{aligned}$$

$$T_3 = 1800 \text{ K} \longrightarrow \begin{aligned} u_3 &= 1487.2 \text{ kJ/kg} \\ P_{r_3} &= 1310 \end{aligned}$$

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \frac{1800 \text{ K}}{539.8 \text{ K}} (800 \text{ kPa}) = 2668 \text{ kPa}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \frac{100 \text{ kPa}}{2668 \text{ kPa}} (1310) = 49.10 \longrightarrow h_4 = 828.1 \text{ kJ/kg}$$

From energy balances,

$$q_{\text{in}} = u_3 - u_2 = 1487.2 - 389.2 = 1098.0 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 828.1 - 300.19 = 527.9 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1098.0 - 527.9 = \mathbf{570.1 \text{ kJ/kg}}$$

(c) Then the thermal efficiency becomes

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{570.1 \text{ kJ/kg}}{1098.0 \text{ kJ/kg}} = \mathbf{51.9\%}$$

**9-16 EES** Problem 9-15 is reconsidered. The effect of the maximum temperature of the cycle on the net work output and thermal efficiency is to be investigated. Also,  $T$ - $s$  and  $P$ - $v$  diagrams for the cycle are to be plotted.

**Analysis** Using EES, the problem is solved as follows:

**"Input Data"**

$T[1]=300$  [K]  
 $P[1]=100$  [kPa]  
 $P[2]=800$  [kPa]

| 2500      | 53.58       | 1775                   | 951.2             |

**9-17** The four processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the maximum temperature in the cycle and the thermal efficiency are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis (b)** From the ideal gas isentropic relations and energy balance,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{1000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 579.2 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2)$$

$$2800 \text{ kJ/kg} = (1.005 \text{ kJ/kg}\cdot\text{K})(T_3 - 579.2) \longrightarrow T_{\text{max}} = T_3 = \mathbf{3360 \text{ K}}$$

$$(c) \quad \frac{P_3 v_3}{T_3} = \frac{P_4 v_4}{T_4} \longrightarrow T_4 = \frac{P_4}{P_3} T_3 = \frac{100 \text{ kPa}}{1000 \text{ kPa}} (3360 \text{ K}) = 336 \text{ K}$$

$$q_{\text{out}} = q_{34, \text{out}} + q_{41, \text{out}} = (u_3 - u_4) + (h_4 - h_1)$$

$$= c_v (T_3 - T_4) + c_p (T_4 - T_1)$$

$$= (0.718 \text{ kJ/kg}\cdot\text{K})(3360 - 336) \text{ K} + (1.005 \text{ kJ/kg}\cdot\text{K})(336 - 300) \text{ K}$$

$$= 2212 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2212 \text{ kJ/kg}}{2800 \text{ kJ/kg}} = \mathbf{21.0\%}$$

**Discussion** The assumption of constant specific heats at room temperature is not realistic in this case the temperature changes involved are too large.

**9-18E** The four processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the total heat input and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17E.

**Analysis** (b) The properties of air at various states are

$$T_1 = 540 \text{ R} \longrightarrow u_1 = 92.04 \text{ Btu/lbm}, \quad h_1 = 129.06 \text{ Btu/lbm}$$

$$q_{\text{in},12} = u_2 - u_1 \longrightarrow u_2 = u_1 + q_{\text{in},12} = 92.04 + 300 = 392.04 \text{ Btu/lbm}$$

$$T_2 = 2116 \text{ R}, \quad h_2 = 537.1 \text{ Btu/lbm}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{2116 \text{ R}}{540 \text{ R}} (14.7 \text{ psia}) = 57.6 \text{ psia}$$

$$T_3 = 3200 \text{ R} \longrightarrow h_3 = 849.48 \text{ Btu/lbm}$$

$$P_{r_3} = 1242$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \frac{14.7 \text{ psia}}{57.6 \text{ psia}} (1242) = 317.0 \longrightarrow h_4 = 593.22 \text{ Btu/lbm}$$

From energy balance,

$$q_{23,\text{in}} = h_3 - h_2 = 849.48 - 537.1 = 312.38 \text{ Btu/lbm}$$

$$q_{\text{in}} = q_{12,\text{in}} + q_{23,\text{in}} = 300 + 312.38 = \mathbf{612.38 \text{ Btu/lbm}}$$

$$q_{\text{out}} = h_4 - h_1 = 593.22 - 129.06 = 464.16 \text{ Btu/lbm}$$

(c) Then the thermal efficiency becomes

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{464.16 \text{ Btu/lbm}}{612.38 \text{ Btu/lbm}} = \mathbf{24.2\%}$$

**9-19E** The four processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the total heat input and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 0.240$  Btu/lbm·R,  $c_v = 0.171$  Btu/lbm·R, and  $k = 1.4$  (Table A-2E).

**Analysis** (b)

$$q_{in,12} = u_2 - u_1 = c_v(T_2 - T_1)$$

$$300 \text{ Btu/lbm} = (0.171 \text{ Btu/lbm} \cdot \text{R})(T_2 - 540) \text{ R}$$

$$T_2 = 2294 \text{ R}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{2294 \text{ R}}{540 \text{ R}} (14.7 \text{ psia}) = 62.46 \text{ psia}$$

$$q_{in,23} = h_3 - h_2 = c_p(T_3 - T_2) = (0.24 \text{ Btu/lbm} \cdot \text{R})(3200 - 2294) \text{ R} = 217.4 \text{ Btu/lbm}$$

Process 3-4 is isentropic:

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (3200 \text{ R}) \left( \frac{14.7 \text{ psia}}{62.46 \text{ psia}} \right)^{0.4/1.4} = 2117 \text{ R}$$

$$q_{in} = q_{in,12} + q_{in,23} = 300 + 217.4 = \mathbf{517.4 \text{ Btu/lbm}}$$

$$q_{out} = h_4 - h_1 = c_p(T_4 - T_1) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2117 - 540) = 378.5 \text{ Btu/lbm}$$

$$(c) \quad \eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{378.5 \text{ Btu/lbm}}{517.4 \text{ Btu/lbm}} = \mathbf{26.8\%}$$

**9-20** The three processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the heat rejected and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (b)

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{1000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 579.2 \text{ K}$$

$$Q_{\text{in}} = m(h_3 - h_2) = mc_p(T_3 - T_2)$$

$$2.76 \text{ kJ} = (0.004 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(T_3 - 579.2) \longrightarrow T_3 = 1266 \text{ K}$$

Process 3-1 is a straight line on the  $P$ - $v$  diagram, thus the  $w_{31}$  is simply the area under the process curve,

$$w_{31} = \text{area} = \frac{P_3 + P_1}{2} (v_1 - v_3) = \frac{P_3 + P_1}{2} \left( \frac{RT_1}{P_1} - \frac{RT_3}{P_3} \right)$$

$$= \left( \frac{1000 + 100 \text{ kPa}}{2} \right) \left( \frac{300 \text{ K}}{100 \text{ kPa}} - \frac{1266 \text{ K}}{1000 \text{ kPa}} \right) (0.287 \text{ kJ/kg}\cdot\text{K})$$

$$= 273.7 \text{ kJ/kg}$$

Energy balance for process 3-1 gives

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \longrightarrow -Q_{31,\text{out}} - W_{31,\text{out}} = m(u_1 - u_3)$$

$$Q_{31,\text{out}} = -mw_{31,\text{out}} - mc_v(T_1 - T_3) = -m[w_{31,\text{out}} + c_v(T_1 - T_3)]$$

$$= -(0.004 \text{ kg})[273.7 + (0.718 \text{ kJ/kg}\cdot\text{K})(300 - 1266)\text{K}] = \mathbf{1.679 \text{ kJ}}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}} = 1 - \frac{1.679 \text{ kJ}}{2.76 \text{ kJ}} = \mathbf{39.2\%}$$

**9-21** The three processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the net work per cycle and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis** (b) The properties of air at various states are

$$T_1 = 290 \text{ K} \longrightarrow \begin{aligned} u_1 &= 206.91 \text{ kJ/kg} \\ h_1 &= 290.16 \text{ kJ/kg} \end{aligned}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow T_2 = \frac{P_2}{P_1} T_1 = \frac{380 \text{ kPa}}{95 \text{ kPa}} (290 \text{ K}) = 1160 \text{ K}$$

$$\longrightarrow u_2 = 897.91 \text{ kJ/kg}, P_{r_2} = 207.2$$

$$P_{r_3} = \frac{P_3}{P_2} P_{r_2} = \frac{95 \text{ kPa}}{380 \text{ kPa}} (207.2) = 51.8 \longrightarrow h_3 = 840.38 \text{ kJ/kg}$$

$$Q_{\text{in}} = m(u_2 - u_1) = (0.003 \text{ kg})(897.91 - 206.91) \text{ kJ/kg} = 2.073 \text{ kJ}$$

$$Q_{\text{out}} = m(h_3 - h_1) = (0.003 \text{ kg})(840.38 - 290.16) \text{ kJ/kg} = 1.651 \text{ kJ}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 2.073 - 1.651 = \mathbf{0.422 \text{ kJ}}$$

$$(c) \quad \eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{0.422 \text{ kJ}}{2.073 \text{ kJ}} = \mathbf{20.4\%}$$

**9-22** The three processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the net work per cycle and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (b) From the isentropic relations and energy balance,

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow T_2 = \frac{P_2}{P_1} T_1 = \frac{380 \text{ kPa}}{95 \text{ kPa}} (290 \text{ K}) = 1160 \text{ K}$$

$$T_3 = T_2 \left( \frac{P_3}{P_2} \right)^{(k-1)/k} = (1160 \text{ K}) \left( \frac{95 \text{ kPa}}{380 \text{ kPa}} \right)^{0.4/1.4} = 780.6 \text{ K}$$

$$\begin{aligned} Q_{\text{in}} &= m(u_2 - u_1) = mc_v(T_2 - T_1) \\ &= (0.003 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(1160 - 290)\text{K} = 1.87 \text{ kJ} \end{aligned}$$

$$\begin{aligned} Q_{\text{out}} &= m(h_3 - h_1) = mc_p(T_3 - T_1) \\ &= (0.003 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(780.6 - 290)\text{K} = 1.48 \text{ kJ} \end{aligned}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 1.87 - 1.48 = \mathbf{0.39 \text{ kJ}}$$

$$(c) \quad \eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{0.39 \text{ kJ}}{1.87 \text{ kJ}} = \mathbf{20.9\%}$$

**9-23** A Carnot cycle with the specified temperature limits is considered. The net work output per cycle is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** The minimum pressure in the cycle is  $P_3$  and the maximum pressure is  $P_1$ . Then,

$$\frac{T_2}{T_3} = \left( \frac{P_2}{P_3} \right)^{(k-1)/k}$$

or

$$P_2 = P_3 \left( \frac{T_2}{T_3} \right)^{k/(k-1)} = (20 \text{ kPa}) \left( \frac{900 \text{ K}}{300 \text{ K}} \right)^{1.4/0.4} = 935.3 \text{ kPa}$$

The heat input is determined from

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{935.3 \text{ kPa}}{2000 \text{ kPa}} = 0.2181 \text{ kJ/kg}\cdot\text{K}$$

$$Q_{\text{in}} = m T_H (s_2 - s_1) = (0.003 \text{ kg})(900 \text{ K})(0.2181 \text{ kJ/kg}\cdot\text{K}) = 0.5889 \text{ kJ}$$

Then,

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{900 \text{ K}} = 66.7\%$$

$$W_{\text{net,out}} = \eta_{\text{th}} Q_{\text{in}} = (0.667)(0.5889 \text{ kJ}) = \mathbf{0.393 \text{ kJ}}$$

**9-24** A Carnot cycle executed in a closed system with air as the working fluid is considered. The minimum pressure in the cycle, the heat rejection from the cycle, the thermal efficiency of the cycle, and the second-law efficiency of an actual cycle operating between the same temperature limits are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperatures are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2).

**Analysis** (a) The minimum temperature is determined from

$$w_{\text{net}} = (s_2 - s_1)(T_H - T_L) \longrightarrow 100 \text{ kJ/kg} = (0.25 \text{ kJ/kg}\cdot\text{K})(750 - T_L)\text{K} \longrightarrow T_L = 350 \text{ K}$$

The pressure at state 4 is determined from

$$\frac{T_1}{T_4} = \left(\frac{P_1}{P_4}\right)^{(k-1)/k}$$

or

$$P_1 = P_4 \left(\frac{T_1}{T_4}\right)^{k/(k-1)}$$

$$800 \text{ kPa} = P_4 \left(\frac{750 \text{ K}}{350 \text{ K}}\right)^{1.4/0.4} \longrightarrow P_4 = 110.1 \text{ kPa}$$

The minimum pressure in the cycle is determined from

$$\Delta s_{12} = -\Delta s_{34} = c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3}$$

$$-0.25 \text{ kJ/kg}\cdot\text{K} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{110.1 \text{ kPa}}{P_3} \longrightarrow P_3 = 46.1 \text{ kPa}$$

(b) The heat rejection from the cycle is

$$q_{\text{out}} = T_L \Delta s_{12} = (350 \text{ K})(0.25 \text{ kJ/kg}\cdot\text{K}) = 87.5 \text{ kJ/kg}$$

(c) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{350 \text{ K}}{750 \text{ K}} = 0.533$$

(d) The power output for the Carnot cycle is

$$\dot{W}_{\text{Carnot}} = \dot{m} w_{\text{net}} = (90 \text{ kg/s})(100 \text{ kJ/kg}) = 9000 \text{ kW}$$

Then, the second-law efficiency of the actual cycle becomes

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{actual}}}{\dot{W}_{\text{Carnot}}} = \frac{5200 \text{ kW}}{9000 \text{ kW}} = 0.578$$

**9-25** An ideal gas Carnot cycle with air as the working fluid is considered. The maximum temperature of the low-temperature energy reservoir, the cycle's thermal efficiency, and the amount of heat that must be supplied per cycle are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The temperature of the low-temperature reservoir can be found by applying the isentropic expansion process relation

$$T_1 = T_2 \left( \frac{v_2}{v_1} \right)^{k-1} = (1027 + 273 \text{ K}) \left( \frac{1}{12} \right)^{1.4-1} = \mathbf{481.1 \text{ K}}$$

Since the Carnot engine is completely reversible, its efficiency is

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{481.1 \text{ K}}{(1027 + 273) \text{ K}} = \mathbf{0.630}$$

The work output per cycle is

$$W_{\text{net}} = \frac{\dot{W}_{\text{net}}}{\dot{n}} = \frac{500 \text{ kJ/s}}{1500 \text{ cycle/min}} \left( \frac{60 \text{ s}}{1 \text{ min}} \right) = 20 \text{ kJ/cycle}$$

According to the definition of the cycle efficiency,

$$\eta_{\text{th,Carnot}} = \frac{W_{\text{net}}}{Q_{\text{in}}} \rightarrow Q_{\text{in}} = \frac{W_{\text{net}}}{\eta_{\text{th,Carnot}}} = \frac{20 \text{ kJ/cycle}}{0.63} = \mathbf{31.75 \text{ kJ/cycle}}$$

**9-26E** The temperatures of the energy reservoirs of an ideal gas Carnot cycle are given. The heat supplied and the work produced per cycle are to be determined.

**Analysis** According to the thermodynamic definition of temperature,

$$Q_H = Q_L \frac{T_H}{T_L} = (100 \text{ Btu}) \frac{(1240 + 460) \text{ R}}{(40 + 460) \text{ R}} = \mathbf{340 \text{ Btu/cycle}}$$

Applying the first law to the cycle gives

$$W_{\text{net}} = Q_H - Q_L = 340 - 100 = \mathbf{240 \text{ Btu/cycle}}$$

## Otto Cycle

**9-27C** The four processes that make up the Otto cycle are (1) isentropic compression, (2)  $v = \text{constant}$  heat addition, (3) isentropic expansion, and (4)  $v = \text{constant}$  heat rejection.

**9-28C** The ideal Otto cycle involves external irreversibilities, and thus it has a lower thermal efficiency.

**9-29C** For actual four-stroke engines, the rpm is twice the number of thermodynamic cycles; for two-stroke engines, it is equal to the number of thermodynamic cycles.

**9-30C** They are analyzed as closed system processes because no mass crosses the system boundaries during any of the processes.

**9-31C** It increases with both of them.

**9-32C** Because high compression ratios cause engine knock.

**9-33C** The thermal efficiency will be the highest for argon because it has the highest specific heat ratio,  $k = 1.667$ .

**9-34C** The fuel is injected into the cylinder in both engines, but it is ignited with a spark plug in gasoline engines.

**9-35** An ideal Otto cycle is considered. The thermal efficiency and the rate of heat input are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The definition of cycle thermal efficiency reduces to

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{12^{1.4-1}} = \mathbf{0.630}$$

The rate of heat addition is then

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{200 \text{ kW}}{0.630} = \mathbf{318 \text{ kW}}$$

**9-36** An ideal Otto cycle is considered. The thermal efficiency and the rate of heat input are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The definition of cycle thermal efficiency reduces to

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{10^{1.4-1}} = \mathbf{0.602}$$

The rate of heat addition is then

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{200 \text{ kW}}{0.602} = \mathbf{332 \text{ kW}}$$

**9-37E** An Otto cycle with non-isentropic compression and expansion processes is considered. The thermal efficiency, the heat addition, and the mean effective pressure are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-1E),  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$ ,  $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** We begin by determining the temperatures of the cycle states using the process equations and component efficiencies. The ideal temperature at the end of the compression is then

$$T_{2s} = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (520 \text{ R})(8)^{1.4-1} = 1195 \text{ R}$$

With the isentropic compression efficiency, the actual temperature at the end of the compression is

$$\eta = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta} = (520 \text{ R}) + \frac{(1195 - 520) \text{ R}}{0.85} = 1314 \text{ R}$$

Similarly for the expansion,

$$T_{4s} = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{1}{r} \right)^{k-1} = (2300 + 460 \text{ R}) \left( \frac{1}{8} \right)^{1.4-1} = 1201 \text{ R}$$

$$\eta = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta(T_3 - T_{4s}) = (2760 \text{ R}) - (0.95)(2760 - 1201) \text{ R} = 1279 \text{ R}$$

The specific heat addition is that of process 2-3,

$$q_{\text{in}} = c_v(T_3 - T_2) = (0.171 \text{ Btu/lbm} \cdot \text{R})(2760 - 1314) \text{ R} = \mathbf{247.3 \text{ Btu/lbm}}$$

The net work production is the difference between the work produced by the expansion and that used by the compression,

$$\begin{aligned} w_{\text{net}} &= c_v(T_3 - T_4) - c_v(T_2 - T_1) \\ &= (0.171 \text{ Btu/lbm} \cdot \text{R})(2760 - 1279) \text{ R} - (0.171 \text{ Btu/lbm} \cdot \text{R})(1314 - 520) \text{ R} \\ &= 117.5 \text{ Btu/lbm} \end{aligned}$$

The thermal efficiency of this cycle is then

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{117.5 \text{ Btu/lbm}}{247.3 \text{ Btu/lbm}} = \mathbf{0.475}$$

At the beginning of compression, the maximum specific volume of this cycle is

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(520 \text{ R})}{13 \text{ psia}} = 14.82 \text{ ft}^3/\text{lbm}$$

while the minimum specific volume of the cycle occurs at the end of the compression

$$v_2 = \frac{v_1}{r} = \frac{14.82 \text{ ft}^3/\text{lbm}}{8} = 1.852 \text{ ft}^3/\text{lbm}$$

The engine's mean effective pressure is then

$$\text{MEP} = \frac{w_{\text{net}}}{v_1 - v_2} = \frac{117.5 \text{ Btu/lbm}}{(14.82 - 1.852) \text{ ft}^3/\text{lbm}} \left( \frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) = \mathbf{49.0 \text{ psia}}$$

**9-38** An ideal Otto cycle with air as the working fluid has a compression ratio of 9.5. The highest pressure and temperature in the cycle, the amount of heat transferred, the thermal efficiency, and the mean effective pressure are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (308 \text{ K})(9.5)^{0.4} = 757.9 \text{ K}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{v_1}{v_2} \frac{T_2}{T_1} P_1 = (9.5) \left( \frac{757.9 \text{ K}}{308 \text{ K}} \right) (100 \text{ kPa}) = 2338 \text{ kPa}$$

Process 3-4: isentropic expansion.

$$T_3 = T_4 \left( \frac{v_4}{v_3} \right)^{k-1} = (800 \text{ K})(9.5)^{0.4} = \mathbf{1969 \text{ K}}$$

Process 2-3:  $v = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \left( \frac{1969 \text{ K}}{757.9 \text{ K}} \right) (2338 \text{ kPa}) = \mathbf{6072 \text{ kPa}}$$

$$(b) \quad m = \frac{P_1 v_1}{RT_1} = \frac{(100 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(308 \text{ K})} = 6.788 \times 10^{-4} \text{ kg}$$

$$Q_{\text{in}} = m(u_3 - u_2) = mc_v(T_3 - T_2) = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(1969 - 757.9) \text{ K} = \mathbf{0.590 \text{ kJ}}$$

(c) Process 4-1:  $v = \text{constant}$  heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) = -(6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(800 - 308) \text{ K} = \mathbf{0.240 \text{ kJ}}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 0.590 - 0.240 = 0.350 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net, out}}}{Q_{\text{in}}} = \frac{0.350 \text{ kJ}}{0.590 \text{ kJ}} = \mathbf{59.4\%}$$

$$(d) \quad v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{W_{\text{net, out}}}{v_1 - v_2} = \frac{W_{\text{net, out}}}{v_1(1 - 1/r)} = \frac{0.350 \text{ kJ}}{(0.0006 \text{ m}^3)(1 - 1/9.5)} \left( \frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{652 \text{ kPa}}$$

**9-39** An Otto cycle with air as the working fluid has a compression ratio of 9.5. The highest pressure and temperature in the cycle, the amount of heat transferred, the thermal efficiency, and the mean effective pressure are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2**

Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ ,  $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$ ,  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (308 \text{ K})(9.5)^{0.4} = 757.9 \text{ K}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{v_1}{v_2} \frac{T_2}{T_1} P_1 = (9.5) \left( \frac{757.9 \text{ K}}{308 \text{ K}} \right) (100 \text{ kPa}) = 2338 \text{ kPa}$$

Process 3-4: polytropic expansion.

$$m = \frac{P_1 v_1}{RT_1} = \frac{(100 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(308 \text{ K})} = 6.788 \times 10^{-4} \text{ kg}$$

$$T_3 = T_4 \left( \frac{v_4}{v_3} \right)^{n-1} = (800 \text{ K})(9.5)^{0.35} = 1759 \text{ K}$$

$$W_{34} = \frac{mR(T_4 - T_3)}{1 - n} = \frac{(6.788 \times 10^{-4} \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(800 - 1759) \text{ K}}{1 - 1.35} = 0.5338 \text{ kJ}$$

Then energy balance for process 3-4 gives

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$Q_{34,\text{in}} - W_{34,\text{out}} = m(u_4 - u_3)$$

$$Q_{34,\text{in}} = m(u_4 - u_3) + W_{34,\text{out}} = mc_v(T_4 - T_3) + W_{34,\text{out}}$$

$$Q_{34,\text{in}} = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(800 - 1759) \text{ K} + 0.5338 \text{ kJ} = 0.0664 \text{ kJ}$$

That is, 0.066 kJ of heat is added to the air during the expansion process (This is not realistic, and probably is due to assuming constant specific heats at room temperature).

(b) Process 2-3:  $v = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \left( \frac{1759 \text{ K}}{757.9 \text{ K}} \right) (2338 \text{ kPa}) = 5426 \text{ kPa}$$

$$Q_{23,\text{in}} = m(u_3 - u_2) = mc_v(T_3 - T_2)$$

$$Q_{23,\text{in}} = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(1759 - 757.9) \text{ K} = 0.4879 \text{ kJ}$$

Therefore,  $Q_{\text{in}} = Q_{23,\text{in}} + Q_{34,\text{in}} = 0.4879 + 0.0664 = 0.5543 \text{ kJ}$

(c) Process 4-1:  $v = \text{constant}$  heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(800 - 308) \text{ K} = 0.2398 \text{ kJ}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 0.5543 - 0.2398 = 0.3145 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{0.3145 \text{ kJ}}{0.5543 \text{ kJ}} = 56.7\%$$

$$(d) \quad v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{W_{\text{net,out}}}{v_1 - v_2} = \frac{W_{\text{net,out}}}{v_1(1 - 1/r)} = \frac{0.3145 \text{ kJ}}{(0.0006 \text{ m}^3)(1 - 1/9.5)} \left( \frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = 586 \text{ kPa}$$

**9-40E** An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The amount of heat transferred to the air during the heat addition process, the thermal efficiency, and the thermal efficiency of a Carnot cycle operating between the same temperature limits are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17E.

**Analysis** (a) Process 1-2: isentropic compression.

$$T_1 = 540\text{R} \longrightarrow \begin{matrix} u_1 = 92.04 \text{ Btu/lbm} \\ v_{r_1} = 144.32 \end{matrix}$$

$$v_{r_2} = \frac{v_2}{v_1} v_{r_2} = \frac{1}{r} v_{r_2} = \frac{1}{8} (144.32) = 18.04 \longrightarrow u_2 = 211.28 \text{ Btu/lbm}$$

Process 2-3:  $v = \text{constant}$  heat addition.

$$T_3 = 2400\text{R} \longrightarrow \begin{matrix} u_3 = 452.70 \text{ Btu/lbm} \\ v_{r_3} = 2.419 \end{matrix}$$

$$q_{in} = u_3 - u_2 = 452.70 - 211.28 = \mathbf{241.42 \text{ Btu/lbm}}$$

(b) Process 3-4: isentropic expansion.

$$v_{r_4} = \frac{v_4}{v_3} v_{r_3} = r v_{r_3} = (8)(2.419) = 19.35 \longrightarrow u_4 = 205.54 \text{ Btu/lbm}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$q_{out} = u_4 - u_1 = 205.54 - 92.04 = 113.50 \text{ Btu/lbm}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{113.50 \text{ Btu/lbm}}{241.42 \text{ Btu/lbm}} = \mathbf{53.0\%}$$

$$(c) \quad \eta_{th,C} = 1 - \frac{T_L}{T_H} = 1 - \frac{540 \text{ R}}{2400 \text{ R}} = \mathbf{77.5\%}$$

**9-41E** An ideal Otto cycle with argon as the working fluid has a compression ratio of 8. The amount of heat transferred to the argon during the heat addition process, the thermal efficiency, and the thermal efficiency of a Carnot cycle operating between the same temperature limits are to be determined.

**Assumptions 1** The air-standard assumptions are applicable with argon as the working fluid. **2** Kinetic and potential energy changes are negligible. **3** Argon is an ideal gas with constant specific heats.

**Properties** The properties of argon are  $c_p = 0.1253$  Btu/lbm.R,  $c_v = 0.0756$  Btu/lbm.R, and  $k = 1.667$  (Table A-2E).

**Analysis** (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (540 \text{ R})(8)^{0.667} = 2161 \text{ R}$$

Process 2-3:  $v = \text{constant}$  heat addition.

$$\begin{aligned} q_{\text{in}} &= u_3 - u_2 = c_v (T_3 - T_2) \\ &= (0.0756 \text{ Btu/lbm.R})(2400 - 2161) \text{ R} \\ &= \mathbf{18.07 \text{ Btu/lbm}} \end{aligned}$$

(b) Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = (2400 \text{ R}) \left( \frac{1}{8} \right)^{0.667} = 600 \text{ R}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.0756 \text{ Btu/lbm.R})(600 - 540) \text{ R} = 4.536 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{4.536 \text{ Btu/lbm}}{18.07 \text{ Btu/lbm}} = \mathbf{74.9\%}$$

$$(c) \quad \eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{540 \text{ R}}{2400 \text{ R}} = \mathbf{77.5\%}$$

**9-42** A gasoline engine operates on an Otto cycle. The compression and expansion processes are modeled as polytropic. The temperature at the end of expansion process, the net work output, the thermal efficiency, the mean effective pressure, the engine speed for a given net power, and the specific fuel consumption are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at 850 K are  $c_p = 1.110 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.823 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.349$  (Table A-2b).

**Analysis** (a) Process 1-2: polytropic compression

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{n-1} = (333 \text{ K})(10)^{1.3-1} = 664.4 \text{ K}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^n = (100 \text{ kPa})(10)^{1.3} = 1995 \text{ kPa}$$

Process 2-3: constant volume heat addition

$$T_3 = T_2 \left( \frac{P_3}{P_2} \right) = (664.4 \text{ K}) \left( \frac{8000 \text{ kPa}}{1995 \text{ kPa}} \right) = 2664 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= u_3 - u_2 = c_v (T_3 - T_2) \\ &= (0.823 \text{ kJ/kg}\cdot\text{K})(2664 - 664.4) \text{ K} = 1646 \text{ kJ/kg} \end{aligned}$$

Process 3-4: polytropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{n-1} = (2664 \text{ K}) \left( \frac{1}{10} \right)^{1.3-1} = 1335 \text{ K}$$

$$P_4 = P_3 \left( \frac{v_3}{v_4} \right)^n = (8000 \text{ kPa}) \left( \frac{1}{10} \right)^{1.3} = 400.9 \text{ kPa}$$

Process 4-1: constant volume heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.823 \text{ kJ/kg}\cdot\text{K})(1335 - 333) \text{ K} = 824.8 \text{ kJ/kg}$$

(b) The net work output and the thermal efficiency are

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1646 - 824.8 = \mathbf{820.9 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{820.9 \text{ kJ/kg}}{1646 \text{ kJ/kg}} = \mathbf{0.499}$$

(c) The mean effective pressure is determined as follows

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(333 \text{ K})}{100 \text{ kPa}} = 0.9557 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{v_1 - v_2} = \frac{w_{\text{net,out}}}{v_1(1 - 1/r)} = \frac{820.9 \text{ kJ/kg}}{(0.9557 \text{ m}^3/\text{kg})(1 - 1/10)} \left( \frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{954.3 \text{ kPa}}$$

(d) The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{V_c + V_d}{V_c} \rightarrow 10 = \frac{V_c + 0.0022 \text{ m}^3}{V_c} \rightarrow V_c = 0.0002444 \text{ m}^3$$

$$V_1 = V_c + V_d = 0.0002444 + 0.0022 = 0.002444 \text{ m}^3$$

The total mass contained in the cylinder is

$$m_t = \frac{P_1 V_1}{R T_1} = \frac{(100 \text{ kPa})/0.002444 \text{ m}^3}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(333 \text{ K})} = 0.002558 \text{ kg}$$

The engine speed for a net power output of 70 kW is

$$\dot{n} = 2 \frac{\dot{W}_{\text{net}}}{m_t w_{\text{net}}} = (2 \text{ rev/cycle}) \frac{70 \text{ kJ/s}}{(0.002558 \text{ kg})(820.9 \text{ kJ/kg} \cdot \text{cycle})} \left( \frac{60 \text{ s}}{1 \text{ min}} \right) = \mathbf{4001 \text{ rev/min}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) The mass of fuel burned during one cycle is

$$\text{AF} = \frac{m_a}{m_f} = \frac{m_t - m_f}{m_f} \rightarrow 16 = \frac{(0.002558 \text{ kg}) - m_f}{m_f} \rightarrow m_f = 0.0001505 \text{ kg}$$

Finally, the specific fuel consumption is

$$\text{sfc} = \frac{m_f}{m_t w_{\text{net}}} = \frac{0.0001505 \text{ kg}}{(0.002558 \text{ kg})(820.9 \text{ kJ/kg})} \left( \frac{1000 \text{ g}}{1 \text{ kg}} \right) \left( \frac{3600 \text{ kJ}}{1 \text{ kWh}} \right) = \mathbf{258.0 \text{ g/kWh}}$$

**9-43E** The properties at various states of an ideal Otto cycle are given. The mean effective pressure is to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-1E),  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$ ,  $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** At the end of the compression, the temperature is

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (520 \text{ R})(9)^{1.4-1} = 1252 \text{ R}$$

while the air temperature at the end of the expansion is

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{1}{r} \right)^{k-1} = (1960 \text{ R}) \left( \frac{1}{9} \right)^{1.4-1} = 813.9 \text{ R}$$

Application of the first law to the compression and expansion processes gives

$$\begin{aligned} w_{\text{net}} &= c_v(T_3 - T_4) - c_v(T_2 - T_1) \\ &= (0.171 \text{ Btu/lbm} \cdot \text{R})(1960 - 813.9) \text{ R} - (0.171 \text{ Btu/lbm} \cdot \text{R})(1252 - 520) \text{ R} \\ &= 70.81 \text{ Btu/lbm} \end{aligned}$$

At the beginning of the compression, the specific volume is

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(520 \text{ R})}{14 \text{ psia}} = 13.76 \text{ ft}^3/\text{lbm}$$

while the specific volume at the end of the compression is

$$v_2 = \frac{v_1}{r} = \frac{13.76 \text{ ft}^3/\text{lbm}}{9} = 1.529 \text{ ft}^3/\text{lbm}$$

The engine's mean effective pressure is then

$$\text{MEP} = \frac{w_{\text{net}}}{v_1 - v_2} = \frac{70.81 \text{ Btu/lbm}}{(13.76 - 1.529) \text{ ft}^3/\text{lbm}} \left( \frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) = \mathbf{31.3 \text{ psia}}$$

**9-44E** The power produced by an ideal Otto cycle is given. The rate of heat addition and rejection are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$  (Table A-1E),  $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ ,  $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{9^{1.4-1}} = 0.5848$$

According to the definition of the thermal efficiency, the rate of heat addition to this cycle is

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{140 \text{ hp}}{0.5848} \left( \frac{2544.5 \text{ Btu/h}}{1 \text{ hp}} \right) = \mathbf{609,100 \text{ Btu/h}}$$

The rate of heat rejection is then

$$\dot{Q}_{\text{out}} = \dot{Q}_{\text{in}} - \dot{W}_{\text{net}} = 609,100 - (140 \times 2544.5 \text{ Btu/h}) = \mathbf{252,900 \text{ Btu/h}}$$

**9-45** The expressions for the maximum gas temperature and pressure of an ideal Otto cycle are to be determined when the compression ratio is doubled.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Analysis** The temperature at the end of the compression varies with the compression ratio as

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1}$$

since  $T_1$  is fixed. The temperature rise during the combustion remains constant since the amount of heat addition is fixed. Then, the maximum cycle temperature is given by

$$T_3 = q_{\text{in}} + T_2 = q_{\text{in}} + T_1 r^{k-1}$$

The smallest gas specific volume during the cycle is

$$v_3 = \frac{v_1}{r}$$

When this is combined with the maximum temperature, the maximum pressure is given by

$$P_3 = \frac{RT_3}{v_3} = \frac{Rr}{v_1} (q_{\text{in}} + T_1 r^{k-1})$$

**9-46** It is to be determined if the polytropic exponent to be used in an Otto cycle model will be greater than or less than the isentropic exponent.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Analysis** During a polytropic process,

$$P\nu^n = \text{constant}$$

$$TP^{(n-1)/n} = \text{constant}$$

and for an isentropic process,

$$P\nu^k = \text{constant}$$

$$TP^{(k-1)/k} = \text{constant}$$

If heat is lost during the expansion of the gas,

$$T_4 > T_{4s}$$

where  $T_{4s}$  is the temperature that would occur if the expansion were reversible and adiabatic ( $n=k$ ). This can only occur when

$$n \leq k$$

**9-47** An ideal Otto cycle is considered. The heat rejection, the net work production, the thermal efficiency, and the mean effective pressure are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The mass in this system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(90 \text{ kPa})(0.004 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})} = 0.004181 \text{ kg}$$

The two unknown temperatures are

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (300 \text{ K})(7)^{1.4-1} = 653.4 \text{ K}$$

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{1}{r} \right)^{k-1} = (1400 \text{ K}) \left( \frac{1}{7} \right)^{1.4-1} = 642.8 \text{ K}$$

Application of the first law to four cycle processes gives

$$W_{1-2} = mc_v(T_2 - T_1) = (0.004181 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(653.4 - 300)\text{K} = 1.061 \text{ kJ}$$

$$Q_{2-3} = mc_v(T_3 - T_2) = (0.004181 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(1400 - 653.4)\text{K} = 2.241 \text{ kJ}$$

$$W_{3-4} = mc_v(T_3 - T_4) = (0.004181 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(1400 - 642.8)\text{K} = 2.273 \text{ kJ}$$

$$Q_{4-1} = mc_v(T_4 - T_1) = (0.004181 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(642.8 - 300)\text{K} = \mathbf{1.029 \text{ kJ}}$$

The net work is

$$W_{\text{net}} = W_{3-4} - W_{1-2} = 2.273 - 1.061 = \mathbf{1.212 \text{ kJ}}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{1.212 \text{ kJ}}{2.241 \text{ kJ}} = \mathbf{0.541}$$

The minimum volume of the cycle occurs at the end of the compression

$$v_2 = \frac{v_1}{r} = \frac{0.004 \text{ m}^3}{7} = 0.0005714 \text{ m}^3$$

The engine's mean effective pressure is then

$$\text{MEP} = \frac{W_{\text{net}}}{v_1 - v_2} = \frac{1.212 \text{ kJ}}{(0.004 - 0.0005714) \text{ m}^3} \left( \frac{1 \text{ kPa}\cdot\text{m}^3}{1 \text{ kJ}} \right) = \mathbf{354 \text{ kPa}}$$

**9-48** The power produced by an ideal Otto cycle is given. The rate of heat addition is to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The compression ratio is

$$r = \frac{v_1}{v_2} = \frac{v_1}{0.15v_1} = 6.667$$

and the thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{6.667^{1.4-1}} = 0.5318$$

The rate at which heat must be added to this engine is then

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{90 \text{ hp}}{0.5318} \left( \frac{0.7457 \text{ kW}}{1 \text{ hp}} \right) = \mathbf{126.2 \text{ kW}}$$

## Diesel Cycle

**9-49C** A diesel engine differs from the gasoline engine in the way combustion is initiated. In diesel engines combustion is initiated by compressing the air above the self-ignition temperature of the fuel whereas it is initiated by a spark plug in a gasoline engine.

**9-50C** The Diesel cycle differs from the Otto cycle in the heat addition process only; it takes place at constant volume in the Otto cycle, but at constant pressure in the Diesel cycle.

**9-51C** The gasoline engine.

**9-52C** Diesel engines operate at high compression ratios because the diesel engines do not have the engine knock problem.

**9-53C** Cutoff ratio is the ratio of the cylinder volumes after and before the combustion process. As the cutoff ratio decreases, the efficiency of the diesel cycle increases.

**9-54** An expression for cutoff ratio of an ideal diesel cycle is to be developed.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Analysis** Employing the isentropic process equations,

$$T_2 = T_1 r^{k-1}$$

while the ideal gas law gives

$$T_3 = T_2 r_c = r_c r^{k-1} T_1$$

When the first law and the closed system work integral is applied to the constant pressure heat addition, the result is

$$q_{in} = c_p (T_3 - T_2) = c_p (r_c r^{k-1} T_1 - r^{k-1} T_1)$$

When this is solved for cutoff ratio, the result is

$$r_c = 1 + \frac{q_{in}}{c_p r_c r^{k-1} T_1}$$

**9-55** An ideal diesel cycle has a compression ratio of 18 and a cutoff ratio of 1.5. The maximum temperature of the air and the rate of heat addition are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** We begin by using the process types to fix the temperatures of the states.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (290 \text{ K})(18)^{1.4-1} = 921.5 \text{ K}$$

$$T_3 = T_2 \left( \frac{v_3}{v_2} \right) = T_2 r_c = (921.5 \text{ K})(1.5) = \mathbf{1382 \text{ K}}$$

Combining the first law as applied to the various processes with the process equations gives

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \frac{r_c^k - 1}{k(r_c - 1)} = 1 - \frac{1}{18^{1.4-1}} \frac{1.5^{1.4} - 1}{1.4(1.5 - 1)} = 0.6565$$

According to the definition of the thermal efficiency,

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{200 \text{ hp}}{0.6565} \left( \frac{0.7457 \text{ kW}}{1 \text{ hp}} \right) = \mathbf{227.2 \text{ kW}}$$

**9-56** A Diesel cycle with non-isentropic compression and expansion processes is considered. The maximum temperature of the air and the rate of heat addition are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** We begin by determining the temperatures of the cycle states using the process equations and component efficiencies. The ideal temperature at the end of the compression is then

$$T_{2s} = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (290 \text{ K})(18)^{1.4-1} = 921.5 \text{ K}$$

With the isentropic compression efficiency, the actual temperature at the end of the compression is

$$\eta = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta} = (290 \text{ K}) + \frac{(921.5 - 290) \text{ K}}{0.90} = 991.7 \text{ K}$$

The maximum temperature is

$$T_3 = T_2 \left( \frac{v_3}{v_2} \right) = T_2 r_c = (991.7 \text{ K})(1.5) = \mathbf{1488 \text{ K}}$$

For the isentropic expansion process,

$$T_{4s} = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{r_c}{r} \right)^{k-1} = (1488 \text{ K}) \left( \frac{1.5}{18} \right)^{1.4-1} = 550.7 \text{ K}$$

since

$$\left. \begin{aligned} r_c &= \frac{v_3}{v_2} \\ r &= \frac{v_4}{v_2} \end{aligned} \right\} \frac{r_c}{r} = \frac{v_3 / v_2}{v_4 / v_2} = \frac{v_3}{v_4}$$

The actual temperature at the end of expansion process is then

$$\eta = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta(T_3 - T_{4s}) = (1488 \text{ K}) - (0.95)(1488 - 550.7) \text{ K} = 597.6 \text{ K}$$

The net work production is the difference between the work produced by the expansion and that used by the compression,

$$\begin{aligned} w_{\text{net}} &= c_v(T_3 - T_4) - c_v(T_2 - T_1) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(1488 - 597.6) \text{ K} - (0.718 \text{ kJ/kg}\cdot\text{K})(991.7 - 290) \text{ K} \\ &= 135.5 \text{ kJ/kg} \end{aligned}$$

The heat addition occurs during process 2-3,

$$q_{\text{in}} = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(1488 - 991.7) \text{ K} = 498.8 \text{ kJ/kg}$$

The thermal efficiency of this cycle is then

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{135.5 \text{ kJ/kg}}{498.8 \text{ kJ/kg}} = 0.2717$$

According to the definition of the thermal efficiency,

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{200 \text{ hp}}{0.2717} \left( \frac{0.7457 \text{ kW}}{1 \text{ hp}} \right) = \mathbf{548.9 \text{ kW}}$$

**9-57** An ideal diesel cycle has a cutoff ratio of 1.2. The power produced is to be determined.

**Assumptions** **1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The specific volume of the air at the start of the compression is

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(288 \text{ K})}{95 \text{ kPa}} = 0.8701 \text{ m}^3/\text{kg}$$

The total air mass taken by all 8 cylinders when they are charged is

$$m = N_{\text{cyl}} \frac{\Delta V}{v_1} = N_{\text{cyl}} \frac{\pi B^2 S / 4}{v_1} = (8) \frac{\pi (0.10 \text{ m})^2 (0.12 \text{ m}) / 4}{0.8701 \text{ m}^3/\text{kg}} = 0.008665 \text{ kg}$$

The rate at which air is processed by the engine is determined from

$$\dot{m} = \frac{m\dot{n}}{N_{\text{rev}}} = \frac{(0.008665 \text{ kg/cycle})(1600/60 \text{ rev/s})}{2 \text{ rev/cycle}} = 0.1155 \text{ kg/s}$$

since there are two revolutions per cycle in a four-stroke engine. The compression ratio is

$$r = \frac{1}{0.05} = 20$$

At the end of the compression, the air temperature is

$$T_2 = T_1 r^{k-1} = (288 \text{ K})(20)^{1.4-1} = 954.6 \text{ K}$$

Application of the first law and work integral to the constant pressure heat addition gives

$$q_{\text{in}} = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg} \cdot \text{K})(2273 - 954.6) \text{ K} = 1325 \text{ kJ/kg}$$

while the thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \frac{r_c^k - 1}{k(r_c - 1)} = 1 - \frac{1}{20^{1.4-1}} \frac{1.2^{1.4} - 1}{1.4(1.2 - 1)} = 0.6867$$

The power produced by this engine is then

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m} w_{\text{net}} = \dot{m} \eta_{\text{th}} q_{\text{in}} \\ &= (0.1155 \text{ kg/s})(0.6867)(1325 \text{ kJ/kg}) \\ &= \mathbf{105.1 \text{ kW}} \end{aligned}$$

**9-58E** An ideal dual cycle has a compression ratio of 20 and cutoff ratio of 1.3. The thermal efficiency, amount of heat added, and the maximum gas pressure and temperature are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-1E),  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$ ,  $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working around the cycle, the germane properties at the various states are

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (530 \text{ R})(20)^{1.4-1} = 1757 \text{ R}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^k = P_1 r^k = (14 \text{ psia})(20)^{1.4} = 928 \text{ psia}$$

$$P_x = P_3 = r_p P_2 = (1.2)(928 \text{ psia}) = \mathbf{1114 \text{ psia}}$$

$$T_x = T_2 \left( \frac{P_x}{P_2} \right) = (1757 \text{ R}) \left( \frac{1114 \text{ psia}}{928 \text{ psia}} \right) = 2109 \text{ R}$$

$$T_3 = T_x \left( \frac{v_3}{v_x} \right) = T_x r_c = (2109 \text{ R})(1.3) = \mathbf{2742 \text{ R}}$$

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{r_c}{r} \right)^{k-1} = (2742 \text{ R}) \left( \frac{1.3}{20} \right)^{1.4-1} = 918.8 \text{ R}$$

Applying the first law and work expression to the heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ &= (0.171 \text{ Btu/lbm} \cdot \text{R})(2109 - 1757) \text{ R} + (0.240 \text{ Btu/lbm} \cdot \text{R})(2742 - 2109) \text{ R} \\ &= \mathbf{212.1 \text{ Btu/lbm}} \end{aligned}$$

The heat rejected is

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.171 \text{ Btu/lbm} \cdot \text{R})(918.8 - 530) \text{ R} = 66.48 \text{ Btu/lbm}$$

Then,

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{66.48 \text{ Btu/lbm}}{212.1 \text{ Btu/lbm}} = \mathbf{0.687}$$

**9-59E** An ideal dual cycle has a compression ratio of 12 and cutoff ratio of 1.3. The thermal efficiency, amount of heat added, and the maximum gas pressure and temperature are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$  (Table A-1E),  $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ ,  $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working around the cycle, the germane properties at the various states are

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (530 \text{ R})(12)^{1.4-1} = 1432 \text{ R}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^k = P_1 r^k = (14 \text{ psia})(12)^{1.4} = 453.9 \text{ psia}$$

$$P_x = P_3 = r_p P_2 = (1.2)(453.9 \text{ psia}) = \mathbf{544.7 \text{ psia}}$$

$$T_x = T_2 \left( \frac{P_x}{P_2} \right) = (1432 \text{ R}) \left( \frac{544.7 \text{ psia}}{453.9 \text{ psia}} \right) = 1718 \text{ R}$$

$$T_3 = T_x \left( \frac{v_3}{v_x} \right) = T_x r_c = (1718 \text{ R})(1.3) = \mathbf{2233 \text{ R}}$$

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{r_c}{r} \right)^{k-1} = (2233 \text{ R}) \left( \frac{1.3}{12} \right)^{1.4-1} = 917.9 \text{ R}$$

Applying the first law and work expression to the heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ &= (0.171 \text{ Btu/lbm}\cdot\text{R})(1718 - 1432) + (0.240 \text{ Btu/lbm}\cdot\text{R})(2233 - 1718) \\ &= \mathbf{172.5 \text{ Btu/lbm}} \end{aligned}$$

The heat rejected is

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.171 \text{ Btu/lbm}\cdot\text{R})(917.9 - 530) = 66.33 \text{ Btu/lbm}$$

Then,

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{66.33 \text{ Btu/lbm}}{172.5 \text{ Btu/lbm}} = \mathbf{0.615}$$

**9-60E** An air-standard Diesel cycle with a compression ratio of 18.2 is considered. The cutoff ratio, the heat rejection per unit mass, and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17E.

**Analysis** (a) Process 1-2: isentropic compression.

$$T_1 = 540 \text{ R} \longrightarrow \begin{matrix} u_1 = 92.04 \text{ Btu/lbm} \\ v_{r_1} = 144.32 \end{matrix}$$

$$v_{r_2} = \frac{v_2}{v_1} v_{r_1} = \frac{1}{r} v_{r_1} = \frac{1}{18.2} (144.32) = 7.93 \longrightarrow \begin{matrix} T_2 = 1623.6 \text{ R} \\ h_2 = 402.05 \text{ Btu/lbm} \end{matrix}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{3000 \text{ R}}{1623.6 \text{ R}} = \mathbf{1.848}$$

$$(b) \quad T_3 = 3000 \text{ R} \longrightarrow \begin{matrix} h_3 = 790.68 \text{ Btu/lbm} \\ v_{r_3} = 1.180 \end{matrix}$$

$$q_{\text{in}} = h_3 - h_2 = 790.68 - 402.05 = 388.63 \text{ Btu/lbm}$$

Process 3-4: isentropic expansion.

$$v_{r_4} = \frac{v_4}{v_3} v_{r_3} = \frac{v_4}{1.848 v_2} v_{r_3} = \frac{r}{1.848} v_{r_3} = \frac{18.2}{1.848} (1.180) = 11.621 \longrightarrow u_4 = 250.91 \text{ Btu/lbm}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 250.91 - 92.04 = \mathbf{158.87 \text{ Btu/lbm}}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{158.87 \text{ Btu/lbm}}{388.63 \text{ Btu/lbm}} = \mathbf{59.1\%}$$

**9-61E** An air-standard Diesel cycle with a compression ratio of 18.2 is considered. The cutoff ratio, the heat rejection per unit mass, and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 0.240$  Btu/lbm.R,  $c_v = 0.171$  Btu/lbm.R, and  $k = 1.4$  (Table A-2E).

**Analysis** (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (540 \text{ R})(18.2)^{0.4} = 1724 \text{ R}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{3000 \text{ R}}{1724 \text{ R}} = \mathbf{1.741}$$

$$(b) \quad q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (0.240 \text{ Btu/lbm.R})(3000 - 1724) \text{ R} = 306 \text{ Btu/lbm}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{1.741 v_2}{v_4} \right)^{k-1} = (3000 \text{ R}) \left( \frac{1.741}{18.2} \right)^{0.4} = 1173 \text{ R}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$\begin{aligned} q_{\text{out}} &= u_4 - u_1 = c_v (T_4 - T_1) \\ &= (0.171 \text{ Btu/lbm.R})(1173 - 540) \text{ R} = \mathbf{108 \text{ Btu/lbm}} \end{aligned}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{108 \text{ Btu/lbm}}{306 \text{ Btu/lbm}} = \mathbf{64.6\%}$$

**9-62** An ideal diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ ,  $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$ ,  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (293 \text{ K})(20)^{0.4} = 971.1 \text{ K}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{2.265 v_2}{v_4} \right)^{k-1} = T_3 \left( \frac{2.265}{r} \right)^{k-1} = (2200 \text{ K}) \left( \frac{2.265}{20} \right)^{0.4} = 920.6 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg} \cdot \text{K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg} \cdot \text{K})(920.6 - 293) \text{ K} = 450.6 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1235 - 450.6 = 784.4 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{784.4 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = 63.5\%$$

$$(b) \quad v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{v_1 - v_2} = \frac{w_{\text{net,out}}}{v_1 (1 - 1/r)} = \frac{784.4 \text{ kJ/kg}}{(0.885 \text{ m}^3/\text{kg})(1 - 1/20)} \left( \frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = 933 \text{ kPa}$$

**9-63** A diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (293 \text{ K})(20)^{0.4} = 971.1 \text{ K}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265$$

Process 3-4: polytropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{n-1} = T_3 \left( \frac{2.265 v_2}{v_4} \right)^{n-1} = T_3 \left( \frac{2.265}{r} \right)^{n-1} = (2200 \text{ K}) \left( \frac{2.265}{20} \right)^{0.35} = 1026 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(1026 - 293) \text{ K} = 526.3 \text{ kJ/kg}$$

Note that  $q_{\text{out}}$  in this case does not represent the entire heat rejected since some heat is also rejected during the polytropic process, which is determined from an energy balance on process 3-4:

$$w_{34, \text{out}} = \frac{R(T_4 - T_3)}{1 - n} = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(1026 - 2200) \text{ K}}{1 - 1.35} = 963 \text{ kJ/kg}$$

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$\begin{aligned} q_{34, \text{in}} - w_{34, \text{out}} &= u_4 - u_3 \longrightarrow q_{34, \text{in}} = w_{34, \text{out}} + c_v (T_4 - T_3) \\ &= 963 \text{ kJ/kg} + (0.718 \text{ kJ/kg}\cdot\text{K})(1026 - 2200) \text{ K} \\ &= 120.1 \text{ kJ/kg} \end{aligned}$$

which means that 120.1 kJ/kg of heat is transferred to the combustion gases during the expansion process. This is unrealistic since the gas is at a much higher temperature than the surroundings, and a hot gas loses heat during polytropic expansion. The cause of this unrealistic result is the constant specific heat assumption. If we were to use  $u$  data from the air table, we would obtain

$$q_{34, \text{in}} = w_{34, \text{out}} + (u_4 - u_3) = 963 + (781.3 - 1872.4) = -128.1 \text{ kJ/kg}$$

which is a heat loss as expected. Then  $q_{\text{out}}$  becomes

$$q_{\text{out}} = q_{34, \text{out}} + q_{41, \text{out}} = 128.1 + 526.3 = 654.4 \text{ kJ/kg}$$

and

$$w_{\text{net, out}} = q_{\text{in}} - q_{\text{out}} = 1235 - 654.4 = 580.6 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net, out}}}{q_{\text{in}}} = \frac{580.6 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = \mathbf{47.0\%}$$

$$(b) \quad v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net, out}}}{v_1 - v_2} = \frac{w_{\text{net, out}}}{v_1 (1 - 1/r)} = \frac{580.6 \text{ kJ/kg}}{(0.885 \text{ m}^3/\text{kg})(1 - 1/20)} \left( \frac{1 \text{ kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{691 \text{ kPa}}$$

**9-64 EES** Problem 9-63 is reconsidered. The effect of the compression ratio on the net work output, mean effective pressure, and thermal efficiency is to be investigated. Also,  $T$ - $s$  and  $P$ - $v$  diagrams for the cycle are to be plotted.

**Analysis** Using EES, the problem is solved as follows:

```

Procedure QTotal(q_12,q_23,q_34,q_41: q_in_total,q_out_total)
q_in_total = 0
q_out_total = 0
IF (q_12 > 0) THEN q_in_total = q_12 ELSE q_out_total = - q_12
If q_23 > 0 then q_in_total = q_in_total + q_23 else q_out_total = q_out_total - q_23
If q_34 > 0 then q_in_total = q_in_total + q_34 else q_out_total = q_out_total - q_34
If q_41 > 0 then q_in_total = q_in_total + q_41 else q_out_total = q_out_total - q_41
END

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (328 \text{ K})(17)^{0.4} = 1019 \text{ K}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow T_3 = \frac{v_3}{v_2} T_2 = 2.2 T_2 = (2.2)(1019 \text{ K}) = 2241 \text{ K}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{2.2 v_2}{v_4} \right)^{k-1} = T_3 \left( \frac{2.2}{r} \right)^{k-1} = (2241 \text{ K}) \left( \frac{2.2}{17} \right)^{0.4} = 989.2 \text{ K}$$

$$m = \frac{P_1 v_1}{RT_1} = \frac{(97 \text{ kPa})(0.0024 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(328 \text{ K})} = 2.391 \times 10^{-3} \text{ kg}$$

$$\begin{aligned} Q_{\text{in}} &= m(h_3 - h_2) = mc_p(T_3 - T_2) \\ &= (2.391 \times 10^{-3} \text{ kg})(1.039 \text{ kJ/kg}\cdot\text{K})(2241 - 1019) \text{ K} = 3.037 \text{ kJ} \end{aligned}$$

$$\begin{aligned} Q_{\text{out}} &= m(u_4 - u_1) = mc_v(T_4 - T_1) \\ &= (2.391 \times 10^{-3} \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K})(989.2 - 328) \text{ K} = 1.175 \text{ kJ} \end{aligned}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 3.037 - 1.175 = 1.863 \text{ kJ/rev}$$

$$\dot{W}_{\text{net,out}} = \dot{n} W_{\text{net,out}} = (1500/60 \text{ rev/s})(1.863 \text{ kJ/rev}) = \mathbf{46.6 \text{ kW}}$$

**Discussion** Note that for 2-stroke engines, 1 thermodynamic cycle is equivalent to 1 mechanical cycle (and thus revolutions).

**9-67** An ideal dual cycle has a compression ratio of 18 and cutoff ratio of 1.1. The power produced by the cycle is to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** We begin by fixing the temperatures at all states.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (291 \text{ K})(18)^{1.4-1} = 924.7 \text{ K}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^k = P_1 r^k = (90 \text{ kPa})(18)^{1.4} = 5148 \text{ kPa}$$

$$P_x = P_3 = r_p P_2 = (1.1)(5148 \text{ kPa}) = 5663 \text{ kPa}$$

$$T_x = T_2 \left( \frac{P_x}{P_2} \right) = (924.7 \text{ K}) \left( \frac{5663 \text{ kPa}}{5148 \text{ kPa}} \right) = 1017 \text{ K}$$

$$T_3 = r_c T_x = (1.1)(1017 \text{ K}) = 1119 \text{ K}$$

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{r_c}{r} \right)^{k-1} = (1119 \text{ K}) \left( \frac{1.1}{18} \right)^{1.4-1} = 365.8 \text{ K}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v(T_2 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(924.7 - 291) \text{ K} = 455.0 \text{ kJ/kg}$$

$$q_{x-3} = c_p(T_3 - T_x) = (1.005 \text{ kJ/kg}\cdot\text{K})(1119 - 1017) \text{ K} = 102.5 \text{ kJ/kg}$$

$$w_{x-3} = q_{x-3} - c_v(T_3 - T_x) = 102.5 - (0.718 \text{ kJ/kg}\cdot\text{K})(1119 - 1017) \text{ K} = 29.26 \text{ kJ/kg}$$

$$w_{3-4} = c_v(T_3 - T_4) = (0.718 \text{ kJ/kg}\cdot\text{K})(1119 - 365.8) \text{ K} = 540.8 \text{ kJ/kg}$$

The net work of the cycle is

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 540.8 + 29.26 - 455.0 = 115.1 \text{ kJ/kg}$$

The mass in the device is given by

$$m = \frac{P_1 v_1}{RT_1} = \frac{(90 \text{ kPa})(0.003 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(291 \text{ K})} = 0.003233 \text{ kg}$$

The net power produced by this engine is then

$$\dot{W}_{\text{net}} = m w_{\text{net}} \dot{n} = (0.003233 \text{ kg/cycle})(115.1 \text{ kJ/kg})(4000/60 \text{ cycle/s}) = \mathbf{24.8 \text{ kW}}$$

**9-68** A dual cycle with non-isentropic compression and expansion processes is considered. The power produced by the cycle is to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** We begin by fixing the temperatures at all states.

$$T_{2s} = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (291 \text{ K})(18)^{1.4-1} = 924.7 \text{ K}$$

$$\eta = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta} = (291 \text{ K}) + \frac{(924.7 - 291) \text{ K}}{0.85} = 1037 \text{ K}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^k = P_1 r^k = (90 \text{ kPa})(18)^{1.4} = 5148 \text{ kPa}$$

$$P_x = P_3 = r_p P_2 = (1.1)(5148 \text{ kPa}) = 5663 \text{ kPa}$$

$$T_x = T_2 \left( \frac{P_x}{P_2} \right) = (1037 \text{ K}) \left( \frac{5663 \text{ kPa}}{5148 \text{ kPa}} \right) = 1141 \text{ K}$$

$$T_3 = r_c T_x = (1.1)(1141 \text{ K}) = 1255 \text{ K}$$

$$T_{4s} = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{r_c}{r} \right)^{k-1} = (1255 \text{ K}) \left( \frac{1.1}{18} \right)^{1.4-1} = 410.3 \text{ K}$$

$$\eta = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta(T_3 - T_{4s}) = (1255 \text{ K}) - (0.90)(1255 - 410.3) \text{ K} = 494.8 \text{ K}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v(T_2 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(1037 - 291) \text{ K} = 535.6 \text{ kJ/kg}$$

$$q_{x-3} = c_p(T_3 - T_x) = (1.005 \text{ kJ/kg}\cdot\text{K})(1255 - 1141) \text{ K} = 114.6 \text{ kJ/kg}$$

$$w_{x-3} = q_{x-3} - c_v(T_3 - T_x) = 114.6 - (0.718 \text{ kJ/kg}\cdot\text{K})(1255 - 1141) \text{ K} = 32.75 \text{ kJ/kg}$$

$$w_{3-4} = c_v(T_3 - T_4) = (0.718 \text{ kJ/kg}\cdot\text{K})(1255 - 494.8) \text{ K} = 545.8 \text{ kJ/kg}$$

The net work of the cycle is

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 545.8 + 32.75 - 535.6 = 42.95 \text{ kJ/kg}$$

The mass in the device is given by

$$m = \frac{P_1 V_1}{RT_1} = \frac{(90 \text{ kPa})(0.003 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(291 \text{ K})} = 0.003233 \text{ kg}$$

The net power produced by this engine is then

$$\dot{W}_{\text{net}} = m w_{\text{net}} \dot{n} = (0.003233 \text{ kg/cycle})(42.95 \text{ kJ/kg})(4000/60 \text{ cycle/s}) = \mathbf{9.26 \text{ kW}}$$

**9-69E** An ideal dual cycle has a compression ratio of 15 and cutoff ratio of 1.4. The net work, heat addition, and the thermal efficiency are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-1E),  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$ ,  $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working around the cycle, the germane properties at the various states are

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (535 \text{ R})(15)^{1.4-1} = 1580 \text{ R}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^k = P_1 r^k = (14.2 \text{ psia})(15)^{1.4} = 629.2 \text{ psia}$$

$$P_x = P_3 = r_p P_2 = (1.1)(629.2 \text{ psia}) = 692.1 \text{ psia}$$

$$T_x = T_2 \left( \frac{P_x}{P_2} \right) = (1580 \text{ R}) \left( \frac{692.1 \text{ psia}}{629.2 \text{ psia}} \right) = 1738 \text{ R}$$

$$T_3 = T_x \left( \frac{v_3}{v_x} \right) = T_x r_c = (1738 \text{ R})(1.4) = 2433 \text{ R}$$

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{r_c}{r} \right)^{k-1} = (2433 \text{ R}) \left( \frac{1.4}{15} \right)^{1.4-1} = 942.2 \text{ R}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v (T_2 - T_1) = (0.171 \text{ Btu/lbm} \cdot \text{R})(1580 - 535) \text{ R} = 178.7 \text{ Btu/lbm}$$

$$q_{2-x} = c_v (T_x - T_2) = (0.171 \text{ Btu/lbm} \cdot \text{R})(1738 - 1580) \text{ R} = 27.02 \text{ Btu/lbm}$$

$$q_{x-3} = c_p (T_3 - T_x) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2433 - 1738) \text{ R} = 166.8 \text{ Btu/lbm}$$

$$w_{x-3} = q_{x-3} - c_v (T_3 - T_x) = 166.8 \text{ Btu/lbm} - (0.171 \text{ Btu/lbm} \cdot \text{R})(2433 - 1738) \text{ R} = 47.96 \text{ Btu/lbm}$$

$$w_{3-4} = c_v (T_3 - T_4) = (0.171 \text{ Btu/lbm} \cdot \text{R})(2433 - 942.2) \text{ R} = 254.9 \text{ Btu/lbm}$$

The net work of the cycle is

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 254.9 + 47.96 - 178.7 = \mathbf{124.2 \text{ Btu/lbm}}$$

and the net heat addition is

$$q_{\text{in}} = q_{2-x} + q_{x-3} = 27.02 + 166.8 = \mathbf{193.8 \text{ Btu/lbm}}$$

Hence, the thermal efficiency is

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{124.2 \text{ Btu/lbm}}{193.8 \text{ Btu/lbm}} = \mathbf{0.641}$$

**9-70** An expression for the thermal efficiency of a dual cycle is to be developed and the thermal efficiency for a given case is to be calculated.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2)

**Analysis** The thermal efficiency of a dual cycle may be expressed as

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_v(T_4 - T_1)}{c_v(T_x - T_2) + c_p(T_3 - T_x)}$$

By applying the isentropic process relations for ideal gases with constant specific heats to the processes 1-2 and 3-4, as well as the ideal gas equation of state, the temperatures may be eliminated from the thermal efficiency expression. This yields the result

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \left[ \frac{r_p r_c^k - 1}{k r_p (r_c - 1) + r_p - 1} \right]$$

where

$$r_p = \frac{P_x}{P_2} \quad \text{and} \quad r_c = \frac{v_3}{v_x}$$

When  $r_c = r_p$ , we obtain

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \left( \frac{r_p^{k+1} - 1}{k(r_p^2 - r_p) + r_p - 1} \right)$$

For the case  $r = 20$  and  $r_p = 2$ ,

$$\eta_{\text{th}} = 1 - \frac{1}{20^{1.4-1}} \left( \frac{2^{1.4+1} - 1}{1.4(2^2 - 2) + 2 - 1} \right) = \mathbf{0.660}$$

**9-71** An expression regarding the thermal efficiency of a dual cycle for a special case is to be obtained.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Analysis** The thermal efficiency of a dual cycle may be expressed as

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_v(T_4 - T_1)}{c_v(T_x - T_2) + c_p(T_3 - T_x)}$$

By applying the isentropic process relations for ideal gases with constant specific heats to the processes 1-2 and 3-4, as well as the ideal gas equation of state, the temperatures may be eliminated from the thermal efficiency expression. This yields the result

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \left[ \frac{r_p r_c^k - 1}{k r_p (r_c - 1) + r_p - 1} \right]$$

where

$$r_p = \frac{P_x}{P_2} \quad \text{and} \quad r_c = \frac{v_3}{v_x}$$

When  $r_c = r_p$ , we obtain

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \left( \frac{r_p^{k+1} - 1}{k(r_p^2 - r_p) + r_p - 1} \right)$$

Rearrangement of this result gives

$$\frac{r_p^{k+1} - 1}{k(r_p^2 - r_p) + r_p - 1} = (1 - \eta_{\text{th}}) r^{k-1}$$

**9-72** A six-cylinder compression ignition engine operates on the ideal Diesel cycle. The maximum temperature in the cycle, the cutoff ratio, the net work output per cycle, the thermal efficiency, the mean effective pressure, the net power output, and the specific fuel consumption are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at 850 K are  $c_p = 1.110$  kJ/kg·K,  $c_v = 0.823$  kJ/kg·K,  $R = 0.287$  kJ/kg·K, and  $k = 1.349$  (Table A-2b).

**Analysis** (a) Process 1-2: Isentropic compression

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (328 \text{ K})(17)^{1.349-1} = 881.7 \text{ K}$$

$$P_2 = P_1 \left( \frac{v_1}{v_2} \right)^k = (95 \text{ kPa})(17)^{1.349} = 4341 \text{ kPa}$$

The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{v_c + v_d}{v_c} \rightarrow 17 = \frac{v_c + 0.0045 \text{ m}^3}{v_c}$$

$$v_c = 0.0002813 \text{ m}^3$$

$$v_1 = v_c + v_d = 0.0002813 + 0.0045 = 0.004781 \text{ m}^3$$

The total mass contained in the cylinder is

$$m = \frac{P_1 v_1}{RT_1} = \frac{(95 \text{ kPa})(0.004781 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(328 \text{ K})} = 0.004825 \text{ kg}$$

The mass of fuel burned during one cycle is

$$AF = \frac{m_a}{m_f} = \frac{m - m_f}{m_f} \rightarrow 24 = \frac{(0.004825 \text{ kg}) - m_f}{m_f} \rightarrow m_f = 0.000193 \text{ kg}$$

Process 2-3: constant pressure heat addition

$$Q_{in} = m_f q_{HV} \eta_c = (0.000193 \text{ kg})(42,500 \text{ kJ/kg})(0.98) = 8.039 \text{ kJ}$$

$$Q_{in} = mc_v(T_3 - T_2) \rightarrow 8.039 \text{ kJ} = (0.004825 \text{ kg})(0.823 \text{ kJ/kg} \cdot \text{K})(T_3 - 881.7 \text{ K}) \rightarrow T_3 = \mathbf{2383 \text{ K}}$$

The cutoff ratio is

$$\beta = \frac{T_3}{T_2} = \frac{2383 \text{ K}}{881.7 \text{ K}} = \mathbf{2.7}$$

$$(b) \quad v_2 = \frac{v_1}{r} = \frac{0.004781 \text{ m}^3}{17} = 0.0002813 \text{ m}^3$$

$$v_3 = \beta v_2 = (2.7)(0.0002813 \text{ m}^3) = 0.00076 \text{ m}^3$$

$$v_4 = v_1$$

$$P_3 = P_2$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{V_3}{V_4} \right)^{k-1} = (2383 \text{ K}) \left( \frac{0.00076 \text{ m}^3}{0.004781 \text{ m}^3} \right)^{1.349-1} = 1254 \text{ K}$$

$$P_4 = P_3 \left( \frac{V_3}{V_4} \right)^k = (4341 \text{ kPa}) \left( \frac{0.00076 \text{ m}^3}{0.004781 \text{ m}^3} \right)^{1.349} = 363.2 \text{ kPa}$$

Process 4-1: constant volume heat rejection.

$$Q_{\text{out}} = mc_v (T_4 - T_1) = (0.004825 \text{ kg})(0.823 \text{ kJ/kg} \cdot \text{K})(1254 - 328) \text{ K} = 3.677 \text{ kJ}$$

The net work output and the thermal efficiency are

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 8.039 - 3.677 = \mathbf{4.361 \text{ kJ}}$$

$$\eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{4.361 \text{ kJ}}{8.039 \text{ kJ}} = \mathbf{0.543}$$

(c) The mean effective pressure is determined to be

$$\text{MEP} = \frac{W_{\text{net,out}}}{V_1 - V_2} = \frac{4.361 \text{ kJ}}{(0.004781 - 0.0002813) \text{ m}^3} \left( \frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = \mathbf{969.2 \text{ kPa}}$$

(d) The power for engine speed of 2000 rpm is

$$\dot{W}_{\text{net}} = W_{\text{net}} \frac{\dot{n}}{2} = (4.361 \text{ kJ/cycle}) \frac{2000 (\text{rev/min})}{(2 \text{ rev/cycle})} \left( \frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{72.7 \text{ kW}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) Finally, the specific fuel consumption is

$$\text{sfc} = \frac{m_f}{W_{\text{net}}} = \frac{0.000193 \text{ kg}}{4.361 \text{ kJ/kg}} \left( \frac{1000 \text{ g}}{1 \text{ kg}} \right) \left( \frac{3600 \text{ kJ}}{1 \text{ kWh}} \right) = \mathbf{159.3 \text{ g/kWh}}$$

## Stirling and Ericsson Cycles

**9-73C** The efficiencies of the Carnot and the Stirling cycles would be the same, the efficiency of the Otto cycle would be less.

**9-74C** The efficiencies of the Carnot and the Ericsson cycles would be the same, the efficiency of the Diesel cycle would be less.

**9-75C** The Stirling cycle.

**9-76C** The two isentropic processes of the Carnot cycle are replaced by two constant pressure regeneration processes in the Ericsson cycle.

**9-77** An ideal steady-flow Ericsson engine with air as the working fluid is considered. The maximum pressure in the cycle, the net work output, and the thermal efficiency of the cycle are to be determined.

**Assumptions** Air is an ideal gas.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1).

**Analysis** (a) The entropy change during process 3-4 is

$$s_4 - s_3 = -\frac{q_{34,\text{out}}}{T_0} = -\frac{150 \text{ kJ/kg}}{300 \text{ K}} = -0.5 \text{ kJ/kg} \cdot \text{K}$$

and

$$\begin{aligned} s_4 - s_3 &= c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} \\ &= -(0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{P_4}{120 \text{ kPa}} = -0.5 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

It yields  $P_4 = 685.2 \text{ kPa}$

(b) For reversible cycles,

$$\frac{q_{\text{out}}}{q_{\text{in}}} = \frac{T_L}{T_H} \longrightarrow q_{\text{in}} = \frac{T_H}{T_L} q_{\text{out}} = \frac{1200 \text{ K}}{300 \text{ K}} (150 \text{ kJ/kg}) = 600 \text{ kJ/kg}$$

Thus,

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 600 - 150 = 450 \text{ kJ/kg}$$

(c) The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{1200 \text{ K}} = 75.0\%$$

**9-78** An ideal Stirling engine with air as the working fluid operates between the specified temperature and pressure limits. The net work produced per cycle and the thermal efficiency of the cycle are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** Since the specific volume is constant during process 2-3,

$$P_2 = P_3 \frac{T_2}{T_3} = (100 \text{ kPa}) \left( \frac{800 \text{ K}}{300 \text{ K}} \right) = 266.7 \text{ kPa}$$

Heat is only added to the system during reversible process 1-2. Then,

$$\begin{aligned} s_2 - s_1 &= c_v \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= 0 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \left( \frac{266.7 \text{ kPa}}{2000 \text{ kPa}} \right) \\ &= 0.5782 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$q_{\text{in}} = T_1 (s_2 - s_1) = (800 \text{ K})(0.5782 \text{ kJ/kg}\cdot\text{K}) = 462.6 \text{ kJ/kg}$$

The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{800 \text{ K}} = \mathbf{0.625}$$

Then,

$$W_{\text{net}} = \eta_{\text{th}} m q_{\text{in}} = (0.625)(1 \text{ kg})(462.6 \text{ kJ/kg}) = \mathbf{289.1 \text{ kJ}}$$

**9-79** An ideal Stirling engine with air as the working fluid operates between the specified temperature and pressure limits. The power produced and the rate of heat input are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** Since the specific volume is constant during process 2-3,

$$P_2 = P_3 \frac{T_2}{T_3} = (100 \text{ kPa}) \left( \frac{800 \text{ K}}{300 \text{ K}} \right) = 266.7 \text{ kPa}$$

Heat is only added to the system during reversible process 1-2. Then,

$$\begin{aligned} s_2 - s_1 &= c_v \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= 0 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \left( \frac{266.7 \text{ kPa}}{2000 \text{ kPa}} \right) \\ &= 0.5782 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$q_{\text{in}} = T_1(s_2 - s_1) = (800 \text{ K})(0.5782 \text{ kJ/kg}\cdot\text{K}) = 462.6 \text{ kJ/kg}$$

The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{800 \text{ K}} = 0.625$$

Then,

$$W_{\text{net}} = \eta_{\text{th}} m q_{\text{in}} = (0.625)(1 \text{ kg})(462.6 \text{ kJ/kg}) = 289.1 \text{ kJ}$$

The rate at which heat is added to this engine is

$$\dot{Q}_{\text{in}} = m q_{\text{in}} \dot{n} = (1 \text{ kg/cycle})(462.6 \text{ kJ/kg})(500/60 \text{ cycle/s}) = \mathbf{3855 \text{ kW}}$$

while the power produced by the engine is

$$\dot{W}_{\text{net}} = W_{\text{net}} \dot{n} = (289.1 \text{ kJ/cycle})(500/60 \text{ cycle/s}) = \mathbf{2409 \text{ kW}}$$

**9-80E** An ideal Stirling engine with hydrogen as the working fluid operates between the specified temperature limits. The amount of external heat addition, external heat rejection, and heat transfer between the working fluid and regenerator per cycle are to be determined.

**Assumptions** Hydrogen is an ideal gas with constant specific heats.

**Properties** The properties of hydrogen at room temperature are  $R = 5.3224 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ ,  $R = 0.9851 \text{ Btu/lbm}\cdot\text{R}$ ,  $c_p = 3.43 \text{ Btu/lbm}\cdot\text{R}$ ,  $c_v = 2.44 \text{ Btu/lbm}\cdot\text{R}$ , and  $k = 1.404$  (Table A-2Ea).

**Analysis** The mass of the air contained in this engine is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(400 \text{ psia})(0.1 \text{ ft}^3)}{(5.3224 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(1100 \text{ R})} = 0.006832 \text{ lbm}$$

At the end of the compression, the pressure will be

$$P_2 = P_1 \frac{V_1}{V_2} = (400 \text{ psia}) \left( \frac{0.1 \text{ ft}^3}{1 \text{ ft}^3} \right) = 40 \text{ psia}$$

The entropy change is

$$\begin{aligned} s_2 - s_1 = s_3 - s_4 &= c_v \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= 0 - (0.9851 \text{ Btu/lbm}\cdot\text{R}) \ln \left( \frac{40 \text{ psia}}{400 \text{ psia}} \right) = 2.268 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

Since the processes are reversible,

$$Q_{\text{in}} = mT_1(s_2 - s_1) = (0.006832 \text{ lbm})(1100 \text{ R})(2.268 \text{ Btu/lbm}\cdot\text{R}) = \mathbf{17.0 \text{ Btu}}$$

$$Q_{\text{out}} = mT_3(s_4 - s_3) = (0.006832 \text{ lbm})(500 \text{ R})(2.268 \text{ Btu/lbm}\cdot\text{R}) = \mathbf{7.75 \text{ Btu}}$$

Applying the first law to the process where the gas passes through the regenerator gives

$$Q_{\text{regen}} = mc_v(T_1 - T_4) = (0.006832 \text{ lbm})(2.44 \text{ Btu/lbm}\cdot\text{R})(1100 - 500) \text{ R} = \mathbf{10.0 \text{ Btu}}$$

**9-81E** An ideal Stirling engine with air as the working fluid operates between specified pressure limits. The heat added to and rejected by this cycle, and the net work produced by the cycle are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ ,  $R = 0.06855 \text{ Btu}/\text{lbm}\cdot\text{R}$ ,  $c_p = 0.240 \text{ Btu}/\text{lbm}\cdot\text{R}$ ,  $c_v = 0.171 \text{ Btu}/\text{lbm}\cdot\text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** Applying the ideal gas equation to the isothermal process 3-4 gives

$$P_4 = P_3 \frac{v_3}{v_4} = (10 \text{ psia})(10) = 100 \text{ psia}$$

Since process 4-1 is a constant volume process,,

$$T_1 = T_4 \left( \frac{P_1}{P_4} \right) = (560 \text{ R}) \left( \frac{600 \text{ psia}}{100 \text{ psia}} \right) = 3360 \text{ R}$$

According to first law and work integral,

$$q_{\text{in}} = w_{1-2} = RT_1 \ln \frac{v_2}{v_1} = (0.06855 \text{ Btu}/\text{lbm}\cdot\text{R})(3360 \text{ R}) \ln(10) = \mathbf{530.3 \text{ Btu}/\text{lbm}}$$

and

$$q_{\text{out}} = w_{3-4} = RT_3 \ln \frac{v_4}{v_3} = (0.06855 \text{ Btu}/\text{lbm}\cdot\text{R})(560 \text{ R}) \ln \left( \frac{1}{10} \right) = \mathbf{88.4 \text{ Btu}/\text{lbm}}$$

The net work is then

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 530.3 - 88.4 = \mathbf{441.9 \text{ Btu}/\text{lbm}}$$

**9-82E** An ideal Stirling engine with air as the working fluid operates between specified pressure limits. The heat transfer in the regenerator is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ ,  $c_p = 0.240 \text{ Btu}/\text{lbm}\cdot\text{R}$ ,  $c_v = 0.171 \text{ Btu}/\text{lbm}\cdot\text{R}$ , and  $k = 1.4$  (Table A-2Ea).

**Analysis** Applying the ideal gas equation to the isothermal process 1-2 gives

$$P_2 = P_1 \frac{v_1}{v_2} = (600 \text{ psia}) \left( \frac{1}{10} \right) = 60 \text{ psia}$$

Since process 2-3 is a constant-volume process,

$$T_2 = T_3 \left( \frac{P_2}{P_3} \right) = (560 \text{ R}) \left( \frac{60 \text{ psia}}{10 \text{ psia}} \right) = 3360 \text{ R}$$

Application of the first law to process 2-3 gives

$$q_{\text{regen}} = c_v (T_2 - T_3) = (0.171 \text{ Btu}/\text{lbm}\cdot\text{R})(3360 - 560) \text{ R} = \mathbf{478.8 \text{ Btu}/\text{lbm}}$$

**9-83** An ideal Ericsson cycle operates between the specified temperature limits. The rate of heat addition is to be determined.

**Analysis** The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{280 \text{ K}}{900 \text{ K}} = 0.6889$$

According to the general definition of the thermal efficiency, the rate of heat addition is

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{500 \text{ kW}}{0.6889} = \mathbf{726 \text{ kW}}$$

**9-84** An ideal Ericsson cycle operates between the specified temperature limits. The power produced by the cycle is to be determined.

**Analysis** The power output is 500 kW when the cycle is repeated 2000 times per minute. Then the work per cycle is

$$W_{\text{net}} = \frac{\dot{W}_{\text{net}}}{\dot{n}} = \frac{500 \text{ kJ/s}}{(2000/60) \text{ cycle/s}} = 15 \text{ kJ/cycle}$$

When the cycle is repeated 3000 times per minute, the power output will be

$$\dot{W}_{\text{net}} = \dot{n} W_{\text{net}} = (3000/60 \text{ cycle/s})(15 \text{ kJ/cycle}) = \mathbf{750 \text{ kW}}$$

**Ideal and Actual Gas-Turbine (Brayton) Cycles**

**9-85C** In gas turbine engines a gas is compressed, and thus the compression work requirements are very large since the steady-flow work is proportional to the specific volume.

**9-86C** They are (1) isentropic compression (in a compressor), (2)  $P = \text{constant}$  heat addition, (3) isentropic expansion (in a turbine), and (4)  $P = \text{constant}$  heat rejection.

**9-87C** For fixed maximum and minimum temperatures, (a) the thermal efficiency increases with pressure ratio, (b) the net work first increases with pressure ratio, reaches a maximum, and then decreases.

**9-88C** Back work ratio is the ratio of the compressor (or pump) work input to the turbine work output. It is usually between 0.40 and 0.6 for gas turbine engines.

**9-89C** As a result of turbine and compressor inefficiencies, (a) the back work ratio increases, and (b) the thermal efficiency decreases.

**9-90E** A simple ideal Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the compressor exit, the back work ratio, and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17E.

**Analysis** (a) Noting that process 1-2 is isentropic,

$$T_1 = 520 \text{ R} \longrightarrow \begin{aligned} h_1 &= 124.27 \text{ Btu/lbm} \\ P_{r_1} &= 1.2147 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (10)(1.2147) = 12.147 \longrightarrow \begin{aligned} T_2 &= \mathbf{996.5 \text{ R}} \\ h_2 &= 240.11 \text{ Btu/lbm} \end{aligned}$$

(b) Process 3-4 is isentropic, and thus

$$T_3 = 2000 \text{ R} \longrightarrow \begin{aligned} h_3 &= 504.71 \text{ Btu/lbm} \\ P_{r_3} &= 174.0 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{10}\right)(174.0) = 17.4 \longrightarrow h_4 = 265.83 \text{ Btu/lbm}$$

$$w_{C,\text{in}} = h_2 - h_1 = 240.11 - 124.27 = 115.84 \text{ Btu/lbm}$$

$$w_{T,\text{out}} = h_3 - h_4 = 504.71 - 265.83 = 238.88 \text{ Btu/lbm}$$

Then the back-work ratio becomes

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{115.84 \text{ Btu/lbm}}{238.88 \text{ Btu/lbm}} = \mathbf{48.5\%}$$

$$(c) \quad q_{\text{in}} = h_3 - h_2 = 504.71 - 240.11 = 264.60 \text{ Btu/lbm}$$

$$w_{\text{net,out}} = w_{T,\text{out}} - w_{C,\text{in}} = 238.88 - 115.84 = 123.04 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{123.04 \text{ Btu/lbm}}{264.60 \text{ Btu/lbm}} = \mathbf{46.5\%}$$

**9-91 [Also solved by EES on enclosed CD]** A simple Brayton cycle with air as the working fluid has a pressure ratio of 8. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis** (a) Noting that process 1-2s is isentropic,

$$T_1 = 310 \text{ K} \longrightarrow \begin{aligned} h_1 &= 310.24 \text{ kJ/kg} \\ P_{r_1} &= 1.5546 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.5546) = 12.44 \longrightarrow h_{2s} = 562.58 \text{ kJ/kg} \text{ and } T_{2s} = 557.25 \text{ K}$$

$$\begin{aligned} \eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} &\longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} \\ &= 310.24 + \frac{562.58 - 310.24}{0.75} = 646.7 \text{ kJ/kg} \end{aligned}$$

$$T_3 = 1160 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1230.92 \text{ kJ/kg} \\ P_{r_3} &= 207.2 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{8}\right)(207.2) = 25.90 \longrightarrow h_{4s} = 692.19 \text{ kJ/kg} \text{ and } T_{4s} = 680.3 \text{ K}$$

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} &\longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1230.92 - (0.82)(1230.92 - 692.19) \\ &= 789.16 \text{ kJ/kg} \end{aligned}$$

Thus,

$$T_4 = 770.1 \text{ K}$$

$$(b) \quad q_{in} = h_3 - h_2 = 1230.92 - 646.7 = 584.2 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = 789.16 - 310.24 = 478.92 \text{ kJ/kg}$$

$$w_{net,out} = q_{in} - q_{out} = 584.2 - 478.92 = 105.3 \text{ kJ/kg}$$

$$(c) \quad \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{105.3 \text{ kJ/kg}}{584.2 \text{ kJ/kg}} = 18.0\%$$

**9-92 EES** Problem 9-91 is reconsidered. The mass flow rate, pressure ratio, turbine inlet temperature, and the isentropic efficiencies of the turbine and compressor are to be varied and a general solution for the problem by taking advantage of the diagram window method for supplying data to EES is to be developed.

**Analysis** Using EES, the problem is solved as follows:

"Input data - from diagram window"

```
{P_ratio = 8}
{T[1] = 310 [K]
P[1] = 100 [kPa]
T[3] = 1160 [K]
m_dot = 20 [kg/s]
Eta_c = 75/100
Eta_t = 82/100}

**9-93** A simple Brayton cycle with air as the working fluid has a pressure ratio of 8. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2).

**Analysis** (a) Using the compressor and turbine efficiency relations,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (310 \text{ K})(8)^{0.4/1.4} = 561.5 \text{ K}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1160 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 640.4 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 310 + \frac{561.5 - 310}{0.75} = 645.3 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

$$= 1160 - (0.82)(1160 - 640.4)$$

$$= 733.9 \text{ K}$$

$$(b) \quad q_{in} = h_3 - h_2 = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(1160 - 645.3)\text{K} = 517.3 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = c_p(T_4 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(733.9 - 310)\text{K} = 426.0 \text{ kJ/kg}$$

$$w_{net,out} = q_{in} - q_{out} = 517.3 - 426.0 = \mathbf{91.3 \text{ kJ/kg}}$$

$$(c) \quad \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{91.3 \text{ kJ/kg}}{517.3 \text{ kJ/kg}} = \mathbf{17.6\%}$$

**9-94** A simple ideal Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The net work and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** Using the isentropic relations for an ideal gas,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{2000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 706.1 \text{ K}$$

Similarly,

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left( \frac{100 \text{ kPa}}{2000 \text{ kPa}} \right)^{0.4/1.4} = 424.9 \text{ K}$$

Applying the first law to the constant-pressure heat addition process 2-3 produces

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg} \cdot \text{K})(1000 - 706.1) \text{ K} = 295.4 \text{ kJ/kg}$$

Similarly,

$$q_{\text{out}} = h_4 - h_1 = c_p (T_4 - T_1) = (1.005 \text{ kJ/kg} \cdot \text{K})(424.9 - 300) \text{ K} = 125.5 \text{ kJ/kg}$$

The net work production is then

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 295.4 - 125.5 = \mathbf{169.9 \text{ kJ/kg}}$$

and the thermal efficiency of this cycle is

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{169.9 \text{ kJ/kg}}{295.4 \text{ kJ/kg}} = \mathbf{0.575}$$

**9-95** A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The net work and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** Using the isentropic relations for an ideal gas,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{2000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 706.1 \text{ K}$$

For the expansion process,

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left( \frac{100 \text{ kPa}}{2000 \text{ kPa}} \right)^{0.4/1.4} = 424.9 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

$$= 1000 - (0.90)(1000 - 424.9)$$

$$= 482.4 \text{ K}$$

Applying the first law to the constant-pressure heat addition process 2-3 produces

$$Q_{in} = m(h_3 - h_2) = mc_p(T_3 - T_2) = (1 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(1000 - 706.1)\text{K} = 295.4 \text{ kJ}$$

Similarly,

$$Q_{out} = m(h_4 - h_1) = mc_p(T_4 - T_1) = (1 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(482.4 - 300)\text{K} = 183.3 \text{ kJ}$$

The net work production is then

$$W_{net} = Q_{in} - Q_{out} = 295.4 - 183.3 = \mathbf{112.1 \text{ kJ}}$$

and the thermal efficiency of this cycle is

$$\eta_{th} = \frac{W_{net}}{Q_{in}} = \frac{112.1 \text{ kJ}}{295.4 \text{ kJ}} = \mathbf{0.379}$$

**9-96** A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The net work and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** For the compression process,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{2000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 706.1 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p (T_{2s} - T_1)}{c_p (T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 300 + \frac{706.1 - 300}{0.80} = 807.6 \text{ K}$$

For the expansion process,

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left( \frac{100 \text{ kPa}}{2000 \text{ kPa}} \right)^{0.4/1.4} = 424.9 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p (T_3 - T_4)}{c_p (T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T (T_3 - T_{4s})$$

$$= 1000 - (0.90)(1000 - 424.9)$$

$$= 482.4 \text{ K}$$

Applying the first law to the constant-pressure heat addition process 2-3 produces

$$Q_{in} = m(h_3 - h_2) = mc_p (T_3 - T_2) = (1 \text{ kg})(1.005 \text{ kJ/kg} \cdot \text{K})(1000 - 807.6) \text{ K} = 193.4 \text{ kJ}$$

Similarly,

$$Q_{out} = m(h_4 - h_1) = mc_p (T_4 - T_1) = (1 \text{ kg})(1.005 \text{ kJ/kg} \cdot \text{K})(482.4 - 300) \text{ K} = 183.3 \text{ kJ}$$

The net work production is then

$$W_{net} = Q_{in} - Q_{out} = 193.4 - 183.3 = \mathbf{10.1 \text{ kJ}}$$

and the thermal efficiency of this cycle is

$$\eta_{th} = \frac{W_{net}}{Q_{in}} = \frac{10.1 \text{ kJ}}{193.4 \text{ kJ}} = \mathbf{0.0522}$$

**9-97** A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The net work and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** For the compression process,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{2000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 706.1 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p (T_{2s} - T_1)}{c_p (T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 300 + \frac{706.1 - 300}{0.80} = 807.6 \text{ K}$$

For the expansion process,

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left( \frac{100 \text{ kPa}}{1950 \text{ kPa}} \right)^{0.4/1.4} = 428.0 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p (T_3 - T_4)}{c_p (T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T (T_3 - T_{4s})$$

$$= 1000 - (0.90)(1000 - 428.0)$$

$$= 485.2 \text{ K}$$

Applying the first law to the constant-pressure heat addition process 2-3 produces

$$Q_{in} = m(h_3 - h_2) = mc_p (T_3 - T_2) = (1 \text{ kg})(1.005 \text{ kJ/kg} \cdot \text{K})(1000 - 807.6) \text{ K} = 193.4 \text{ kJ}$$

Similarly,

$$Q_{out} = m(h_4 - h_1) = mc_p (T_4 - T_1) = (1 \text{ kg})(1.005 \text{ kJ/kg} \cdot \text{K})(485.2 - 300) \text{ K} = 186.1 \text{ kJ}$$

The net work production is then

$$W_{net} = Q_{in} - Q_{out} = 193.4 - 186.1 = \mathbf{7.3 \text{ kJ}}$$

and the thermal efficiency of this cycle is

$$\eta_{th} = \frac{W_{net}}{Q_{in}} = \frac{7.3 \text{ kJ}}{193.4 \text{ kJ}} = \mathbf{0.0377}$$

**9-98** A gas turbine power plant that operates on the simple Brayton cycle with air as the working fluid has a specified pressure ratio. The required mass flow rate of air is to be determined for two cases.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2).

**Analysis** (a) Using the isentropic relations,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(12)^{0.4/1.4} = 610.2 \text{ K}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left( \frac{1}{12} \right)^{0.4/1.4} = 491.7 \text{ K}$$

$$w_{s,C,in} = h_{2s} - h_1 = c_p (T_{2s} - T_1) = (1.005 \text{ kJ/kg} \cdot \text{K})(610.2 - 300) \text{ K} = 311.75 \text{ kJ/kg}$$

$$w_{s,T,out} = h_3 - h_{4s} = c_p (T_3 - T_{4s}) = (1.005 \text{ kJ/kg} \cdot \text{K})(1000 - 491.7) \text{ K} = 510.84 \text{ kJ/kg}$$

$$w_{s,net,out} = w_{s,T,out} - w_{s,C,in} = 510.84 - 311.75 = 199.1 \text{ kJ/kg}$$

$$\dot{m}_s = \frac{\dot{W}_{net,out}}{w_{s,net,out}} = \frac{70,000 \text{ kJ/s}}{199.1 \text{ kJ/kg}} = \mathbf{352 \text{ kg/s}}$$

(b) The net work output is determined to be

$$w_{a,net,out} = w_{a,T,out} - w_{a,C,in} = \eta_T w_{s,T,out} - w_{s,C,in} / \eta_C$$

$$= (0.85)(510.84) - 311.75 / 0.85 = 67.5 \text{ kJ/kg}$$

$$\dot{m}_a = \frac{\dot{W}_{net,out}}{w_{a,net,out}} = \frac{70,000 \text{ kJ/s}}{67.5 \text{ kJ/kg}} = \mathbf{1037 \text{ kg/s}}$$

**9-99** A stationary gas-turbine power plant operates on a simple ideal Brayton cycle with air as the working fluid. The power delivered by this plant is to be determined assuming constant and variable specific heats.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas.

**Analysis** (a) Assuming constant specific heats,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (290 \text{ K})(8)^{0.4/1.4} = 525.3 \text{ K}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1100 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 607.2 \text{ K}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{c_p(T_4 - T_1)}{c_p(T_3 - T_2)} = 1 - \frac{T_4 - T_1}{T_3 - T_2} = 1 - \frac{607.2 - 290}{1100 - 525.3} = 0.448$$

$$\dot{W}_{net,out} = \eta_{th} \dot{Q}_{in} = (0.448)(35,000 \text{ kW}) = \mathbf{15,680 \text{ kW}}$$

(b) Assuming variable specific heats (Table A-17),

$$T_1 = 290 \text{ K} \longrightarrow \begin{aligned} h_1 &= 290.16 \text{ kJ/kg} \\ P_{r_1} &= 1.2311 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.2311) = 9.8488 \longrightarrow h_2 = 526.12 \text{ kJ/kg}$$

$$T_3 = 1100 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1161.07 \text{ kJ/kg} \\ P_{r_3} &= 167.1 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left( \frac{1}{8} \right) (167.1) = 20.89 \longrightarrow h_4 = 651.37 \text{ kJ/kg}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{h_4 - h_1}{h_3 - h_2} = 1 - \frac{651.37 - 290.16}{1161.07 - 526.11} = 0.431$$

$$\dot{W}_{net,out} = \eta_T \dot{Q}_{in} = (0.431)(35,000 \text{ kW}) = \mathbf{15,085 \text{ kW}}$$

**9-100** An actual gas-turbine power plant operates at specified conditions. The fraction of the turbine work output used to drive the compressor and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis** (a) Using the isentropic relations,

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$T_2 = 580 \text{ K} \longrightarrow h_2 = 586.04 \text{ kJ/kg}$$

$$r_p = \frac{P_2}{P_1} = \frac{700}{100} = 7$$

$$q_{\text{in}} = h_3 - h_2 \longrightarrow h_3 = 950 + 586.04 = 1536.04 \text{ kJ/kg}$$

$$\rightarrow P_{r_3} = 474.11$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{7}\right)(474.11) = 67.73 \longrightarrow h_{4s} = 905.83 \text{ kJ/kg}$$

$$w_{\text{C,in}} = h_2 - h_1 = 586.04 - 300.19 = 285.85 \text{ kJ/kg}$$

$$w_{\text{T,out}} = \eta_T (h_3 - h_{4s}) = (0.86)(1536.04 - 905.83) = 542.0 \text{ kJ/kg}$$

Thus,

$$r_{\text{bw}} = \frac{w_{\text{C,in}}}{w_{\text{T,out}}} = \frac{285.85 \text{ kJ/kg}}{542.0 \text{ kJ/kg}} = \mathbf{52.7\%}$$

$$(b) \quad w_{\text{net,out}} = w_{\text{T,out}} - w_{\text{C,in}} = 542.0 - 285.85 = 256.15 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{256.15 \text{ kJ/kg}}{950 \text{ kJ/kg}} = \mathbf{27.0\%}$$

**9-101** A gas-turbine power plant operates at specified conditions. The fraction of the turbine work output used to drive the compressor and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2).

**Analysis** (a) Using constant specific heats,

$$r_p = \frac{P_2}{P_1} = \frac{700}{100} = 7$$

$$\begin{aligned} q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) &\longrightarrow T_3 = T_2 + q_{\text{in}}/c_p \\ &= 580 \text{ K} + (950 \text{ kJ/kg})/(1.005 \text{ kJ/kg} \cdot \text{K}) \\ &= 1525.3 \text{ K} \end{aligned}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1525.3 \text{ K}) \left( \frac{1}{7} \right)^{0.4/1.4} = 874.8 \text{ K}$$

$$w_{C,\text{in}} = h_2 - h_1 = c_p (T_2 - T_1) = (1.005 \text{ kJ/kg} \cdot \text{K})(580 - 300) \text{ K} = 281.4 \text{ kJ/kg}$$

$$w_{T,\text{out}} = \eta_T (h_3 - h_{4s}) = \eta_T c_p (T_3 - T_{4s}) = (0.86)(1.005 \text{ kJ/kg} \cdot \text{K})(1525.3 - 874.8) \text{ K} = 562.2 \text{ kJ/kg}$$

Thus,

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{281.4 \text{ kJ/kg}}{562.2 \text{ kJ/kg}} = \mathbf{50.1\%}$$

(b)  $w_{\text{net,out}} = w_{T,\text{out}} - w_{C,\text{in}} = 562.2 - 281.4 = 280.8 \text{ kJ/kg}$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{280.8 \text{ kJ/kg}}{950 \text{ kJ/kg}} = \mathbf{29.6\%}$$

**9-102E** A simple ideal Brayton cycle with argon as the working fluid operates between the specified temperature and pressure limits. The rate of heat addition, the power produced, and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Argon is an ideal gas with constant specific heats.

**Properties** The properties of argon at room temperature are  $R = 0.2686 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-1E),  $c_p = 0.1253 \text{ Btu/lbm} \cdot \text{R}$  and  $k = 1.667$  (Table A-2Ea).

**Analysis** At the compressor inlet,

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.2686 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(540 \text{ R})}{15 \text{ psia}} = 9.670 \text{ ft}^3/\text{lbm}$$

$$\dot{m} = \frac{A_1 V_1}{\nu_1} = \frac{(3 \text{ ft}^2)(200 \text{ ft/s})}{9.670 \text{ ft}^3/\text{lbm}} = 62.05 \text{ lbm/s}$$

According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (540 \text{ R}) \left( \frac{150 \text{ psia}}{15 \text{ psia}} \right)^{0.667/1.667} = 1357 \text{ R}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1660 \text{ R}) \left( \frac{15 \text{ psia}}{150 \text{ psia}} \right)^{0.667/1.667} = 660.7 \text{ R}$$

Applying the first law to the constant-pressure heat addition process 2-3 gives

$$\dot{Q}_{\text{in}} = \dot{m} c_p (T_3 - T_2) = (62.05 \text{ lbm/s})(0.1253 \text{ Btu/lbm} \cdot \text{R})(1660 - 1357) \text{ R} = \mathbf{2356 \text{ Btu/s}}$$

The net power output is

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m} c_p (T_3 - T_4 + T_1 - T_2) \\ &= (62.05 \text{ lbm/s})(0.1253 \text{ Btu/lbm} \cdot \text{R})(1660 - 660.7 + 540 - 1357) \text{ R} \\ &= \mathbf{1417 \text{ Btu/s}} \end{aligned}$$

The thermal efficiency of this cycle is then

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1417 \text{ Btu/s}}{2356 \text{ Btu/s}} = \mathbf{0.601}$$

**9-103** An aircraft engine operates as a simple ideal Brayton cycle with air as the working fluid. The pressure ratio and the rate of heat input are given. The net power and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** For the isentropic compression process,

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(10)^{0.4/1.4} = 527.1 \text{ K}$$

The heat addition is

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{500 \text{ kW}}{1 \text{ kg/s}} = 500 \text{ kJ/kg}$$

Applying the first law to the heat addition process,

$$q_{\text{in}} = c_p (T_3 - T_2)$$

$$T_3 = T_2 + \frac{q_{\text{in}}}{c_p} = 527.1 \text{ K} + \frac{500 \text{ kJ/kg}}{1.005 \text{ kJ/kg} \cdot \text{K}} = 1025 \text{ K}$$

The temperature at the exit of the turbine is

$$T_4 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1025 \text{ K}) \left( \frac{1}{10} \right)^{0.4/1.4} = 530.9 \text{ K}$$

Applying the first law to the adiabatic turbine and the compressor produce

$$w_T = c_p (T_3 - T_4) = (1.005 \text{ kJ/kg} \cdot \text{K})(1025 - 530.9) \text{ K} = 496.6 \text{ kJ/kg}$$

$$w_C = c_p (T_2 - T_1) = (1.005 \text{ kJ/kg} \cdot \text{K})(527.1 - 273) \text{ K} = 255.4 \text{ kJ/kg}$$

The net power produced by the engine is then

$$\dot{W}_{\text{net}} = \dot{m}(w_T - w_C) = (1 \text{ kg/s})(496.6 - 255.4) \text{ kJ/kg} = \mathbf{241.2 \text{ kW}}$$

Finally the thermal efficiency is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{241.2 \text{ kW}}{500 \text{ kW}} = \mathbf{0.482}$$

**9-104** An aircraft engine operates as a simple ideal Brayton cycle with air as the working fluid. The pressure ratio and the rate of heat input are given. The net power and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** For the isentropic compression process,

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(15)^{0.4/1.4} = 591.8 \text{ K}$$

The heat addition is

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{500 \text{ kW}}{1 \text{ kg/s}} = 500 \text{ kJ/kg}$$

Applying the first law to the heat addition process,

$$q_{\text{in}} = c_p (T_3 - T_2)$$

$$T_3 = T_2 + \frac{q_{\text{in}}}{c_p} = 591.8 \text{ K} + \frac{500 \text{ kJ/kg}}{1.005 \text{ kJ/kg} \cdot \text{K}} = 1089 \text{ K}$$

The temperature at the exit of the turbine is

$$T_4 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1089 \text{ K}) \left( \frac{1}{15} \right)^{0.4/1.4} = 502.3 \text{ K}$$

Applying the first law to the adiabatic turbine and the compressor produce

$$w_T = c_p (T_3 - T_4) = (1.005 \text{ kJ/kg} \cdot \text{K})(1089 - 502.3) \text{ K} = 589.6 \text{ kJ/kg}$$

$$w_C = c_p (T_2 - T_1) = (1.005 \text{ kJ/kg} \cdot \text{K})(591.8 - 273) \text{ K} = 320.4 \text{ kJ/kg}$$

The net power produced by the engine is then

$$\dot{W}_{\text{net}} = \dot{m}(w_T - w_C) = (1 \text{ kg/s})(589.6 - 320.4) \text{ kJ/kg} = \mathbf{269.2 \text{ kW}}$$

Finally the thermal efficiency is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{269.2 \text{ kW}}{500 \text{ kW}} = \mathbf{0.538}$$

**9-105** A gas-turbine plant operates on the simple Brayton cycle. The net power output, the back work ratio, and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1).

**Analysis** (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Compression

$$T_1 = 30^\circ\text{C} \longrightarrow h_1 = 303.60 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_1 = 30^\circ\text{C} \\ P_1 = 100 \text{ kPa} \end{array} \right\} s_1 = 5.7159 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_2 = s_1 = 5.7159 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 617.37 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.82 = \frac{617.37 - 303.60}{h_2 - 303.60} \longrightarrow h_2 = 686.24 \text{ kJ/kg}$$

Process 3-4: Expansion

$$T_4 = 500^\circ\text{C} \longrightarrow h_4 = 792.62 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.88 = \frac{h_3 - 792.62}{h_3 - h_{4s}}$$

We cannot find the enthalpy at state 3 directly. However, using the following lines in EES together with the isentropic efficiency relation, we find  $h_3 = 1404.7 \text{ kJ/kg}$ ,  $T_3 = 1034^\circ\text{C}$ ,  $s_3 = 6.5699 \text{ kJ/kg} \cdot \text{K}$ . The solution by hand would require a trial-error approach.

$$h_3 = \text{enthalpy}(\text{Air}, T=T_3)$$

$$s_3 = \text{entropy}(\text{Air}, T=T_3, P=P_2)$$

$$h_{4s} = \text{enthalpy}(\text{Air}, P=P_1, s=s_3)$$

The mass flow rate is determined from

$$\dot{m} = \frac{P_1 \dot{V}_1}{RT_1} = \frac{(100 \text{ kPa})(150/60 \text{ m}^3/\text{s})}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(30 + 273 \text{ K})} = 2.875 \text{ kg/s}$$

The net power output is

$$\dot{W}_{C,\text{in}} = \dot{m}(h_2 - h_1) = (2.875 \text{ kg/s})(686.24 - 303.60) \text{ kJ/kg} = 1100 \text{ kW}$$

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (2.875 \text{ kg/s})(1404.7 - 792.62) \text{ kJ/kg} = 1759 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{T,\text{out}} - \dot{W}_{C,\text{in}} = 1759 - 1100 = \mathbf{659 \text{ kW}}$$

(b) The back work ratio is

$$r_{\text{bw}} = \frac{\dot{W}_{C,\text{in}}}{\dot{W}_{T,\text{out}}} = \frac{1100 \text{ kW}}{1759 \text{ kW}} = \mathbf{0.625}$$

(c) The rate of heat input and the thermal efficiency are

$$\dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (2.875 \text{ kg/s})(1404.7 - 686.24) \text{ kJ/kg} = 2065 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{659 \text{ kW}}{2065 \text{ kW}} = \mathbf{0.319}$$

## Brayton Cycle with Regeneration

**9-106C** Regeneration increases the thermal efficiency of a Brayton cycle by capturing some of the waste heat from the exhaust gases and preheating the air before it enters the combustion chamber.

**9-107C** Yes. At very high compression ratios, the gas temperature at the turbine exit may be lower than the temperature at the compressor exit. Therefore, if these two streams are brought into thermal contact in a regenerator, heat will flow to the exhaust gases instead of from the exhaust gases. As a result, the thermal efficiency will decrease.

**9-108C** The extent to which a regenerator approaches an ideal regenerator is called the effectiveness  $\varepsilon$ , and is defined as  $\varepsilon = q_{\text{regen, act}} / q_{\text{regen, max}}$ .

**9-109C** (b) turbine exit.

**9-110C** The steam injected increases the mass flow rate through the turbine and thus the power output. This, in turn, increases the thermal efficiency since  $\eta = W / Q_{\text{in}}$  and  $W$  increases while  $Q_{\text{in}}$  remains constant. Steam can be obtained by utilizing the hot exhaust gases.

**9-111** A Brayton cycle with regeneration produces 150 kW power. The rates of heat addition and rejection are to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (293 \text{ K})(8)^{0.4/1.4} = 530.8 \text{ K}$$

$$T_5 = T_4 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 592.3 \text{ K}$$

When the first law is applied to the heat exchanger, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 10 = 592.3 - 10 = 582.3 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - (T_3 - T_2) = 592.3 - (582.3 - 530.8) = 540.8 \text{ K}$$

Application of the first law to the turbine and compressor gives

$$\begin{aligned} w_{\text{net}} &= c_p (T_4 - T_5) - c_p (T_2 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 592.3) \text{ K} - (1.005 \text{ kJ/kg}\cdot\text{K})(530.8 - 293) \text{ K} \\ &= 244.1 \text{ kJ/kg} \end{aligned}$$

Then,

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150 \text{ kW}}{244.1 \text{ kJ/kg}} = 0.6145 \text{ kg/s}$$

Applying the first law to the combustion chamber produces

$$\dot{Q}_{\text{in}} = \dot{m} c_p (T_4 - T_3) = (0.6145 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 582.3) \text{ K} = \mathbf{303.0 \text{ kW}}$$

Similarly,

$$\dot{Q}_{\text{out}} = \dot{m} c_p (T_6 - T_1) = (0.6145 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(540.8 - 293) \text{ K} = \mathbf{153.0 \text{ kW}}$$

**9-112** A Brayton cycle with regeneration produces 150 kW power. The rates of heat addition and rejection are to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** For the compression and expansion processes we have

$$T_{2s} = T_1 r_p^{(k-1)/k} = (293 \text{ K})(8)^{0.4/1.4} = 530.8 \text{ K}$$

$$\eta_C = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 293 + \frac{530.8 - 293}{0.87} = 566.3 \text{ K}$$

$$T_{5s} = T_4 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 592.3 \text{ K}$$

$$\eta_T = \frac{c_p(T_4 - T_5)}{c_p(T_4 - T_{5s})} \longrightarrow T_5 = T_4 - \eta_T(T_4 - T_{5s})$$

$$= 1073 - (0.93)(1073 - 592.3)$$

$$= 625.9 \text{ K}$$

When the first law is applied to the heat exchanger, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 10 = 625.9 - 10 = 615.9 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - (T_3 - T_2) = 625.9 - (615.9 - 566.3) = 576.3 \text{ K}$$

Application of the first law to the turbine and compressor gives

$$w_{\text{net}} = c_p(T_4 - T_5) - c_p(T_2 - T_1)$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 625.9) \text{ K} - (1.005 \text{ kJ/kg}\cdot\text{K})(566.3 - 293) \text{ K}$$

$$= 174.7 \text{ kJ/kg}$$

Then,

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150 \text{ kW}}{174.7 \text{ kJ/kg}} = 0.8586 \text{ kg/s}$$

Applying the first law to the combustion chamber produces

$$\dot{Q}_{\text{in}} = \dot{m} c_p(T_4 - T_3) = (0.8586 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 615.9) \text{ K} = \mathbf{394.4 \text{ kW}}$$

Similarly,

$$\dot{Q}_{\text{out}} = \dot{m} c_p(T_6 - T_1) = (0.8586 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(576.3 - 293) \text{ K} = \mathbf{244.5 \text{ kW}}$$

**9-113** A Brayton cycle with regeneration is considered. The thermal efficiencies of the cycle for parallel-flow and counter-flow arrangements of the regenerator are to be compared.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (293 \text{ K})(7)^{0.4/1.4} = 510.9 \text{ K}$$

$$T_5 = T_4 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1000 \text{ K}) \left( \frac{1}{7} \right)^{0.4/1.4} = 573.5 \text{ K}$$

When the first law is applied to the heat exchanger as originally arranged, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 6 = 573.5 - 6 = 567.5 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - T_3 + T_2 = 573.5 - 567.5 + 510.9 = 516.9 \text{ K}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{516.9 - 293}{1000 - 567.5} = \mathbf{0.482}$$

For the rearranged version of this cycle,

$$T_3 = T_6 - 6$$

An energy balance on the heat exchanger gives

$$T_3 - T_2 = T_5 - T_6$$

The solution of these two equations is

$$T_3 = 539.2 \text{ K}$$

$$T_6 = 545.2 \text{ K}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{545.2 - 293}{1000 - 539.2} = \mathbf{0.453}$$

**9-114E** An ideal Brayton cycle with regeneration has a pressure ratio of 8. The thermal efficiency of the cycle is to be determined with and without regenerator cases.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (510 \text{ R})(8)^{0.4/1.4} = 923.8 \text{ R}$$

$$T_5 = T_4 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1960 \text{ R}) \left( \frac{1}{8} \right)^{0.4/1.4} = 1082 \text{ R}$$

The regenerator is ideal (i.e., the effectiveness is 100%) and thus,

$$T_3 = T_5 = 1082 \text{ R}$$

$$T_6 = T_2 = 923.8 \text{ R}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{923.8 - 510}{1960 - 1082} = \mathbf{0.529}$$

The solution without a regenerator is as follows:

$$T_2 = T_1 r_p^{(k-1)/k} = (510 \text{ R})(8)^{0.4/1.4} = 923.8 \text{ R}$$

$$T_4 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1960 \text{ R}) \left( \frac{1}{8} \right)^{0.4/1.4} = 1082 \text{ R}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_4 - T_1}{T_3 - T_2} = 1 - \frac{1082 - 510}{1960 - 923.8} = \mathbf{0.448}$$

**9-115** An expression for the thermal efficiency of an ideal Brayton cycle with an ideal regenerator is to be developed.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

**Analysis** The expressions for the isentropic compression and expansion processes are

$$T_2 = T_1 r_p^{(k-1)/k}$$

$$T_4 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k}$$

For an ideal regenerator,

$$T_5 = T_4$$

$$T_6 = T_2$$

The thermal efficiency of the cycle is

$$\begin{aligned} \eta_{\text{th}} &= 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{T_1}{T_3} \frac{(T_6 / T_1) - 1}{1 - (T_5 / T_3)} \\ &= 1 - \frac{T_1}{T_3} \frac{(T_2 / T_1) - 1}{1 - (T_4 / T_3)} \\ &= 1 - \frac{T_1}{T_3} \frac{r_p^{(k-1)/k} - 1}{1 - r_p^{-(k-1)/k}} \\ &= 1 - \frac{T_1}{T_3} r_p^{(k-1)/k} \end{aligned}$$

**9-116E** A car is powered by a gas turbine with a pressure ratio of 4. The thermal efficiency of the car and the mass flow rate of air for a net power output of 95 hp are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 The ambient air is 540 R and 14.5 psia. 4 The effectiveness of the regenerator is 0.9, and the isentropic efficiencies for both the compressor and the turbine are 80%. 5 The combustion gases can be treated as air.

**Properties** The properties of air at the compressor and turbine inlet temperatures can be obtained from Table A-17E.

**Analysis** The gas turbine cycle with regeneration can be analyzed as follows:

$$T_1 = 540 \text{ R} \longrightarrow h_1 = 129.06 \text{ Btu/lbm}$$

$$P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (4)(1.386) = 5.544 \longrightarrow h_{2s} = 192.0 \text{ Btu/lbm}$$

$$T_3 = 2160 \text{ R} \longrightarrow h_3 = 549.35 \text{ Btu/lbm}$$

$$P_{r_3} = 230.12$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{4}\right)(230.12) = 57.53 \longrightarrow h_{4s} = 372.2 \text{ Btu/lbm}$$

and

$$\eta_{\text{comp}} = \frac{h_{2s} - h_1}{h_2 - h_1} \rightarrow 0.80 = \frac{192.0 - 129.06}{h_2 - 129.06} \rightarrow h_2 = 207.74 \text{ Btu/lbm}$$

$$\eta_{\text{turb}} = \frac{h_3 - h_4}{h_3 - h_{4s}} \rightarrow 0.80 = \frac{549.35 - h_4}{549.35 - 372.2} \rightarrow h_4 = 407.63 \text{ Btu/lbm}$$

Then the thermal efficiency of the gas turbine cycle becomes

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = 0.9(407.63 - 207.74) = 179.9 \text{ Btu/lbm}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (549.35 - 207.74) - 179.9 = 161.7 \text{ Btu/lbm}$$

$$w_{\text{net,out}} = w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) = (549.35 - 407.63) - (207.74 - 129.06) = 63.0 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{63.0 \text{ Btu/lbm}}{161.7 \text{ Btu/lbm}} = 0.39 = \mathbf{39\%}$$

Finally, the mass flow rate of air through the turbine becomes

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{95 \text{ hp}}{63.0 \text{ Btu/lbm}} \left( \frac{0.7068 \text{ Btu/s}}{1 \text{ hp}} \right) = \mathbf{1.07 \text{ lbm/s}}$$

**9-117 [Also solved by EES on enclosed CD]** The thermal efficiency and power output of an actual gas turbine are given. The isentropic efficiency of the turbine and of the compressor, and the thermal efficiency of the gas turbine modified with a regenerator are to be determined.

**Assumptions** 1 Air is an ideal gas with variable specific heats. 2 Kinetic and potential energy changes are negligible. 3 The mass flow rates of air and of the combustion gases are the same, and the properties of combustion gases are the same as those of air.

**Properties** The properties of air are given in Table A-17.

**Analysis** The properties at various states are

$$T_1 = 20^\circ\text{C} = 293 \text{ K} \longrightarrow \begin{matrix} h_1 = 293.2 \text{ kJ/kg} \\ P_{r_1} = 1.2765 \end{matrix}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (14.7)(1.2765) = 18.765 \longrightarrow h_{2s} = 643.3 \text{ kJ/kg}$$

$$T_3 = 1288^\circ\text{C} = 1561 \text{ K} \longrightarrow \begin{matrix} h_3 = 1710.0 \text{ kJ/kg} \\ P_{r_3} = 712.5 \end{matrix}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{14.7}\right)(712.5) = 48.47 \longrightarrow h_{4s} = 825.23 \text{ kJ/kg}$$

The net work output and the heat input per unit mass are

$$w_{\text{net}} = \frac{\dot{W}_{\text{net}}}{\dot{m}} = \frac{159,000 \text{ kW}}{1,536,000 \text{ kg/h}} \left( \frac{3600 \text{ s}}{1 \text{ h}} \right) = 372.66 \text{ kJ/kg}$$

$$q_{\text{in}} = \frac{w_{\text{net}}}{\eta_{\text{th}}} = \frac{372.66 \text{ kJ/kg}}{0.359} = 1038.0 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 \rightarrow h_2 = h_3 - q_{\text{in}} = 1710 - 1038 = 672.0 \text{ kJ/kg}$$

$$q_{\text{out}} = q_{\text{in}} - w_{\text{net}} = 1038.0 - 372.66 = 665.34 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 \rightarrow h_4 = q_{\text{out}} + h_1 = 665.34 + 293.2 = 958.54 \text{ kJ/kg} \rightarrow T_4 = 650^\circ\text{C}$$

Then the compressor and turbine efficiencies become

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{1710 - 958.54}{1710 - 825.23} = \mathbf{0.849}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{643.3 - 293.2}{672 - 293.2} = \mathbf{0.924}$$

When a regenerator is added, the new heat input and the thermal efficiency become

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.80)(958.54 - 672.0) = 286.54 \text{ kJ/kg}$$

$$q_{\text{in,new}} = q_{\text{in}} - q_{\text{regen}} = 1038 - 286.54 = 751.46 \text{ kJ/kg}$$

$$\eta_{\text{th,new}} = \frac{w_{\text{net}}}{q_{\text{in,new}}} = \frac{372.66 \text{ kJ/kg}}{751.46 \text{ kJ/kg}} = \mathbf{0.496}$$

**Discussion** Note an 80% efficient regenerator would increase the thermal efficiency of this gas turbine from 35.9% to 49.6%.

**9-118 EES** Problem 9-117 is reconsidered. A solution that allows different isentropic efficiencies for the compressor and turbine is to be developed and the effect of the isentropic efficiencies on net work done and the heat supplied to the cycle is to be studied. Also, the  $T$ - $s$  diagram for the cycle is to be plotted.

**Analysis** Using EES, the problem is solved as follows:

"Input data"

$T[3] = 1288$  [C]  
 $Pratio = 14.7$   
 $T[1] = 20$  [C]  
 $P[1] = 100$  [kPa]  
 $\{T[4]=589$  [C] $\}$   
 $\{W\_dot\_net=159$  [MW] $\}$  "We omit the information about the cycle net work"  
 $m\_dot = 1536000$  [kg/h]\*Convert(kg/h,kg/s)  
 $\{Eta\_th\_noreg=0.359\}$  "We omit the information about the cycle efficiency."  
 $Eta\_reg = 0.80$   
 $Eta\_c = 0.892$  "Compressor isentropic efficiency"  
 $Eta\_t = 0.926$  "Turbine isentropic efficiency"

"Isentropic Compressor analysis"

**9-119** A Brayton cycle with regeneration using air as the working fluid is considered. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air are given in Table A-17.

**Analysis** (a) The properties of air at various states are

$$T_1 = 310 \text{ K} \longrightarrow \begin{matrix} h_1 = 310.24 \text{ kJ/kg} \\ P_{r_1} = 1.5546 \end{matrix}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (7)(1.5546) = 10.88 \longrightarrow h_{2s} = 541.26 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + (h_{2s} - h_1)/\eta_C = 310.24 + (541.26 - 310.24)/(0.75) = 618.26 \text{ kJ/kg}$$

$$T_3 = 1150 \text{ K} \longrightarrow \begin{matrix} h_3 = 1219.25 \text{ kJ/kg} \\ P_{r_3} = 200.15 \end{matrix}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{7}\right)(200.15) = 28.59 \longrightarrow h_{4s} = 711.80 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1219.25 - (0.82)(1219.25 - 711.80) = 803.14 \text{ kJ/kg}$$

Thus,

$$T_4 = \mathbf{782.8 \text{ K}}$$

$$\begin{aligned} (b) \quad w_{\text{net}} &= w_{T,\text{out}} - w_{C,\text{in}} = (h_3 - h_4) - (h_2 - h_1) \\ &= (1219.25 - 803.14) - (618.26 - 310.24) \\ &= \mathbf{108.09 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} (c) \quad \varepsilon &= \frac{h_5 - h_2}{h_4 - h_2} \longrightarrow h_5 = h_2 + \varepsilon(h_4 - h_2) \\ &= 618.26 + (0.65)(803.14 - 618.26) \\ &= \mathbf{738.43 \text{ kJ/kg}} \end{aligned}$$

Then,

$$q_{\text{in}} = h_3 - h_5 = 1219.25 - 738.43 = 480.82 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{108.09 \text{ kJ/kg}}{480.82 \text{ kJ/kg}} = \mathbf{22.5\%}$$

**9-120** A stationary gas-turbine power plant operating on an ideal regenerative Brayton cycle with air as the working fluid is considered. The power delivered by this plant is to be determined for two cases.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas. **3** Kinetic and potential energy changes are negligible.

**Properties** When assuming constant specific heats, the properties of air at room temperature are  $c_p = 1.005$  kJ/kg.K and  $k = 1.4$  (Table A-2a). When assuming variable specific heats, the properties of air are obtained from Table A-17.

**Analysis (a)** Assuming constant specific heats,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (290 \text{ K})(8)^{0.4/1.4} = 525.3 \text{ K}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1100 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 607.2 \text{ K}$$

$$\varepsilon = 100\% \longrightarrow T_5 = T_4 = 607.2 \text{ K and } T_6 = T_2 = 525.3 \text{ K}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_p(T_6 - T_1)}{c_p(T_3 - T_5)} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{525.3 - 290}{1100 - 607.2} = 0.5225$$

$$\dot{W}_{\text{net}} = \eta_T \dot{Q}_{\text{in}} = (0.5225)(75,000 \text{ kW}) = \mathbf{39,188 \text{ kW}}$$

**(b)** Assuming variable specific heats,

$$T_1 = 290 \text{ K} \longrightarrow \begin{aligned} h_1 &= 290.16 \text{ kJ/kg} \\ P_{r_1} &= 1.2311 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.2311) = 9.8488 \longrightarrow h_2 = 526.12 \text{ kJ/kg}$$

$$T_3 = 1100 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1161.07 \text{ kJ/kg} \\ P_{r_3} &= 167.1 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left( \frac{1}{8} \right) (167.1) = 20.89 \longrightarrow h_4 = 651.37 \text{ kJ/kg}$$

$$\varepsilon = 100\% \longrightarrow h_5 = h_4 = 651.37 \text{ kJ/kg and } h_6 = h_2 = 526.12 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{h_6 - h_1}{h_3 - h_5} = 1 - \frac{526.12 - 290.16}{1161.07 - 651.37} = 0.5371$$

$$\dot{W}_{\text{net}} = \eta_T \dot{Q}_{\text{in}} = (0.5371)(75,000 \text{ kW}) = \mathbf{40,283 \text{ kW}}$$

**9-121** A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air are given in Table A-17.

**Analysis** (a) The properties at various states are

$$r_p = P_2 / P_1 = 800 / 100 = 8$$

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$T_2 = 580 \text{ K} \longrightarrow h_2 = 586.04 \text{ kJ/kg}$$

$$T_3 = 1200 \text{ K} \longrightarrow h_3 = 1277.79 \text{ kJ/kg}$$

$$P_{r_3} = 238.0$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{8}\right)(238.0) = 29.75 \longrightarrow h_{4s} = 719.75 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} &\longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) \\ &= 1277.79 - (0.86)(1277.79 - 719.75) \\ &= 797.88 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.72)(797.88 - 586.04) = \mathbf{152.5 \text{ kJ/kg}}$$

$$\begin{aligned} (b) \quad w_{\text{net}} &= w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) \\ &= (1277.79 - 797.88) - (586.04 - 300.19) = 194.06 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (1277.79 - 586.04) - 152.52 = 539.23 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{194.06 \text{ kJ/kg}}{539.23 \text{ kJ/kg}} = \mathbf{36.0\%}$$

**9-122** A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** (a) Using the isentropic relations and turbine efficiency,

$$r_p = P_2 / P_1 = 800 / 100 = 8$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1200 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 662.5 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

$$= 1200 - (0.86)(1200 - 662.5)$$

$$= 737.8 \text{ K}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = \varepsilon c_p(T_4 - T_2) = (0.72)(1.005 \text{ kJ/kg}\cdot\text{K})(737.8 - 580) \text{ K} = \mathbf{114.2 \text{ kJ/kg}}$$

$$(b) \quad w_{\text{net}} = w_{\text{T,out}} - w_{\text{C,in}} = c_p(T_3 - T_4) - c_p(T_2 - T_1)$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})[(1200 - 737.8) - (580 - 300)] \text{ K} = 183.1 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = c_p(T_3 - T_2) - q_{\text{regen}}$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})(1200 - 580) \text{ K} - 114.2 = 508.9 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{183.1 \text{ kJ/kg}}{508.9 \text{ kJ/kg}} = \mathbf{36.0\%}$$

**9-123** A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

**Brayton Cycle with Intercooling, Reheating, and Regeneration**

**9-124C** As the number of compression and expansion stages are increased and regeneration is employed, the ideal Brayton cycle will approach the Ericsson cycle.

**9-125C** (a) decrease, (b) decrease, and (c) decrease.

**9-126C** (a) increase, (b) decrease, and (c) decrease.

**9-127C** (a) increase, (b) decrease, (c) decrease, and (d) increase.

**9-128C** (a) increase, (b) decrease, (c) increase, and (d) decrease.

**9-129C** Because the steady-flow work is proportional to the specific volume of the gas. Intercooling decreases the average specific volume of the gas during compression, and thus the compressor work. Reheating increases the average specific volume of the gas, and thus the turbine work output.

**9-130C** (c) The Carnot (or Ericsson) cycle efficiency.

**9-131** An ideal gas-turbine cycle with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency of the cycle are to be determined for the cases of with and without a regenerator.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air are given in Table A-17.

**Analysis (a)** The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine since this is an ideal cycle. Then,

$$T_1 = 300 \text{ K} \longrightarrow \begin{matrix} h_1 = 300.19 \text{ kJ/kg} \\ P_{r_1} = 1.386 \end{matrix}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_2 = h_4 = 411.26 \text{ kJ/kg}$$

$$T_5 = 1200 \text{ K} \longrightarrow \begin{matrix} h_5 = h_7 = 1277.79 \text{ kJ/kg} \\ P_{r_5} = 238 \end{matrix}$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_6 = h_8 = 946.36 \text{ kJ/kg}$$

$$w_{C,\text{in}} = 2(h_2 - h_1) = 2(411.26 - 300.19) = 222.14 \text{ kJ/kg}$$

$$w_{T,\text{out}} = 2(h_5 - h_6) = 2(1277.79 - 946.36) = 662.86 \text{ kJ/kg}$$

Thus,

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{222.14 \text{ kJ/kg}}{662.86 \text{ kJ/kg}} = \mathbf{33.5\%}$$

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) = (1277.79 - 411.26) + (1277.79 - 946.36) = 1197.96 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 662.86 - 222.14 = 440.72 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{440.72 \text{ kJ/kg}}{1197.96 \text{ kJ/kg}} = \mathbf{36.8\%}$$

(b) When a regenerator is used,  $r_{\text{bw}}$  remains the same. The thermal efficiency in this case becomes

$$q_{\text{regen}} = \varepsilon(h_8 - h_4) = (0.75)(946.36 - 411.26) = 401.33 \text{ kJ/kg}$$

$$q_{\text{in}} = q_{\text{in,old}} - q_{\text{regen}} = 1197.96 - 401.33 = 796.63 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{440.72 \text{ kJ/kg}}{796.63 \text{ kJ/kg}} = \mathbf{55.3\%}$$

**9-132** A gas-turbine cycle with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency of the cycle are to be determined for the cases of with and without a regenerator.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air are given in Table A-17.

**Analysis** (a) The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine. Then,

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_{2s} = h_{4s} = 411.26 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_4 = h_1 + (h_{2s} - h_1) / \eta_C$$

$$= 300.19 + (411.26 - 300.19) / (0.80)$$

$$= 439.03 \text{ kJ/kg}$$

$$T_5 = 1200 \text{ K} \longrightarrow h_5 = h_7 = 1277.79 \text{ kJ/kg}$$

$$P_{r_5} = 238$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_6 = h_8 = 946.36 \text{ kJ/kg}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_8 = h_5 - \eta_T (h_5 - h_{6s})$$

$$= 1277.79 - (0.85)(1277.79 - 946.36)$$

$$= 996.07 \text{ kJ/kg}$$

$$w_{C,\text{in}} = 2(h_2 - h_1) = 2(439.03 - 300.19) = 277.68 \text{ kJ/kg}$$

$$w_{T,\text{out}} = 2(h_5 - h_6) = 2(1277.79 - 996.07) = 563.44 \text{ kJ/kg}$$

Thus,

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{277.68 \text{ kJ/kg}}{563.44 \text{ kJ/kg}} = \mathbf{49.3\%}$$

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) = (1277.79 - 439.03) + (1277.79 - 996.07) = 1120.48 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 563.44 - 277.68 = 285.76 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{285.76 \text{ kJ/kg}}{1120.48 \text{ kJ/kg}} = \mathbf{25.5\%}$$

(b) When a regenerator is used,  $r_{\text{bw}}$  remains the same. The thermal efficiency in this case becomes

$$q_{\text{regen}} = \varepsilon(h_8 - h_4) = (0.75)(996.07 - 439.03) = 417.78 \text{ kJ/kg}$$

$$q_{\text{in}} = q_{\text{in,old}} - q_{\text{regen}} = 1120.48 - 417.78 = 702.70 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{285.76 \text{ kJ/kg}}{702.70 \text{ kJ/kg}} = \mathbf{40.7\%}$$

**9-133E** A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The mass flow rate of air and the rates of heat addition and rejection for a specified net power output are to be determined.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 0.24 \text{ Btu/lbm} \cdot \text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** According to the isentropic process expressions for an ideal gas,

$$T_2 = T_4 = T_1 r_p^{(k-1)/k} = (520 \text{ R})(3)^{0.4/1.4} = 711.7 \text{ R}$$

$$T_7 = T_9 = T_6 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1400 \text{ R}) \left( \frac{1}{3} \right)^{0.4/1.4} = 1023 \text{ R}$$

The regenerator is ideal (i.e., the effectiveness is 100%) and thus,

$$T_5 = T_7 = 1023 \text{ R}$$

$$T_{10} = T_2 = 711.7 \text{ R}$$

The net work output is determined as follows

$$w_{C,in} = 2c_p(T_2 - T_1) = 2(0.24 \text{ Btu/lbm} \cdot \text{R})(711.7 - 520) \text{ R} = 92.02 \text{ Btu/lbm}$$

$$w_{T,out} = 2c_p(T_6 - T_7) = 2(0.24 \text{ Btu/lbm} \cdot \text{R})(1400 - 1023) \text{ R} = 180.96 \text{ Btu/lbm}$$

$$w_{net} = w_{T,out} - w_{C,in} = 180.96 - 92.02 = 88.94 \text{ Btu/lbm}$$

The mass flow rate is then

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{1000 \text{ hp}}{88.94 \text{ Btu/lbm}} \left( \frac{0.7068 \text{ Btu/s}}{1 \text{ hp}} \right) = \mathbf{7.947 \text{ lbm/s}}$$

Applying the first law to the heat addition processes gives

$$\begin{aligned} \dot{Q}_{in} &= \dot{m}c_p(T_6 - T_5) + \dot{m}c_p(T_8 - T_7) \\ &= (7.947 \text{ lbm/s})(0.24 \text{ Btu/lbm} \cdot \text{R})(1400 - 1023 + 1400 - 1023) \text{ R} \\ &= \mathbf{1438 \text{ Btu/s}} \end{aligned}$$

Similarly,

$$\begin{aligned} \dot{Q}_{out} &= \dot{m}c_p(T_{10} - T_1) + \dot{m}c_p(T_2 - T_3) \\ &= (7.947 \text{ lbm/s})(0.24 \text{ Btu/lbm} \cdot \text{R})(711.7 - 520 + 711.7 - 520) \text{ R} \\ &= \mathbf{731 \text{ Btu/s}} \end{aligned}$$

**9-134E** A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The mass flow rate of air and the rates of heat addition and rejection for a specified net power output are to be determined.

**Assumptions** 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 0.24 \text{ Btu/lbm} \cdot \text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** For the compression and expansion processes, we have

$$T_{2s} = T_{4s} = T_1 r_p^{(k-1)/k} = (520 \text{ R})(3)^{0.4/1.4} = 711.7 \text{ R}$$

$$\eta_C = \frac{c_p (T_{2s} - T_1)}{c_p (T_2 - T_1)} \rightarrow T_2 = T_4 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 520 + \frac{711.7 - 520}{0.88} = 737.8 \text{ R}$$

$$T_{7s} = T_{9s} = T_6 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1400 \text{ R}) \left( \frac{1}{3} \right)^{0.4/1.4} = 1023 \text{ R}$$

$$\eta_T = \frac{c_p (T_6 - T_7)}{c_p (T_6 - T_{7s})} \rightarrow T_7 = T_9 = T_6 - \eta_T (T_6 - T_{7s})$$

$$= 1400 - (0.93)(1400 - 1023) = 1049 \text{ R}$$

The regenerator is ideal (i.e., the effectiveness is 100%) and thus,

$$T_5 = T_7 = 1049 \text{ R}$$

$$T_{10} = T_2 = 737.8 \text{ R}$$

The net work output is determined as follows

$$w_{C,in} = 2c_p (T_2 - T_1) = 2(0.24 \text{ Btu/lbm} \cdot \text{R})(737.8 - 520) \text{ R} = 104.54 \text{ Btu/lbm}$$

$$w_{T,out} = 2c_p (T_6 - T_7) = 2(0.24 \text{ Btu/lbm} \cdot \text{R})(1400 - 1049) \text{ R} = 168.48 \text{ Btu/lbm}$$

$$w_{net} = w_{T,out} - w_{C,in} = 168.48 - 104.54 = 63.94 \text{ Btu/lbm}$$

The mass flow rate is then

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{1000 \text{ hp}}{63.94 \text{ Btu/lbm}} \left( \frac{0.7068 \text{ Btu/s}}{1 \text{ hp}} \right) = 11.05 \text{ lbm/s}$$

The rate of heat addition is then

$$\dot{Q}_{in} = \dot{m}c_p (T_6 - T_5) + \dot{m}c_p (T_8 - T_7)$$

$$= (11.05 \text{ lbm/s})(0.24 \text{ Btu/lbm} \cdot \text{R})(1400 - 1049 + 1400 - 1049) \text{ R}$$

$$= \mathbf{1862 \text{ Btu/s}}$$

**9-135** A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The temperatures at various states are obtained as follows

$$T_2 = T_4 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

$$T_5 = T_4 + 20 = 430.9 + 20 = 450.9 \text{ K}$$

$$q_{\text{in}} = c_p (T_6 - T_5)$$

$$T_6 = T_5 + \frac{q_{\text{in}}}{c_p} = 450.9 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 749.4 \text{ K}$$

$$T_7 = T_6 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (749.4 \text{ K}) \left( \frac{1}{4} \right)^{0.4/1.4} = 504.3 \text{ K}$$

$$T_8 = T_7 + \frac{q_{\text{in}}}{c_p} = 504.3 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 802.8 \text{ K}$$

$$T_9 = T_8 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (802.8 \text{ K}) \left( \frac{1}{4} \right)^{0.4/1.4} = 540.2 \text{ K}$$

$$T_{10} = T_9 - 20 = 540.2 - 20 = 520.2 \text{ K}$$

The heat input is

$$q_{\text{in}} = 300 + 300 = 600 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p (T_{10} - T_1) + c_p (T_2 - T_3) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(520.2 - 290 + 430.9 - 290) \text{ K} \\ &= 373.0 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{373.0}{600} = \mathbf{0.378}$$

**9-136** A regenerative gas-turbine cycle with three stages of compression and three stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The temperatures at various states are obtained as follows

$$T_2 = T_4 = T_6 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

$$T_7 = T_6 + 20 = 430.9 + 20 = 450.9 \text{ K}$$

$$q_{\text{in}} = c_p (T_8 - T_7)$$

$$T_8 = T_7 + \frac{q_{\text{in}}}{c_p} = 450.9 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 749.4 \text{ K}$$

$$T_9 = T_8 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (749.4 \text{ K}) \left( \frac{1}{4} \right)^{0.4/1.4} = 504.3 \text{ K}$$

$$T_{10} = T_9 + \frac{q_{\text{in}}}{c_p} = 504.3 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 802.8 \text{ K}$$

$$T_{11} = T_{10} \left( \frac{1}{r_p} \right)^{(k-1)/k} = (802.8 \text{ K}) \left( \frac{1}{4} \right)^{0.4/1.4} = 540.2 \text{ K}$$

$$T_{12} = T_{11} + \frac{q_{\text{in}}}{c_p} = 540.2 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 838.7 \text{ K}$$

$$T_{13} = T_{12} \left( \frac{1}{r_p} \right)^{(k-1)/k} = (838.7 \text{ K}) \left( \frac{1}{4} \right)^{0.4/1.4} = 564.4 \text{ K}$$

$$T_{14} = T_{13} - 20 = 564.4 - 20 = 544.4 \text{ K}$$

The heat input is

$$q_{\text{in}} = 300 + 300 + 300 = 900 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p (T_{14} - T_1) + c_p (T_2 - T_3) + c_p (T_4 - T_5) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(544.4 - 290 + 430.9 - 290 + 430.9 - 290) \text{ K} \\ &= 538.9 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{538.9}{900} = \mathbf{0.401}$$

**9-137** A regenerative gas-turbine cycle with three stages of compression and three stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** Since all compressors share the same compression ratio and begin at the same temperature,

$$T_2 = T_4 = T_6 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

From the problem statement,

$$T_7 = T_{13} - 40$$

The relations for heat input and expansion processes are

$$q_{\text{in}} = c_p (T_8 - T_7) \longrightarrow T_8 = T_7 + \frac{q_{\text{in}}}{c_p}$$

$$T_9 = T_8 \left( \frac{1}{r_p} \right)^{(k-1)/k}$$

$$T_{10} = T_9 + \frac{q_{\text{in}}}{c_p}, \quad T_{11} = T_{10} \left( \frac{1}{r_p} \right)^{(k-1)/k}$$

$$T_{12} = T_{11} + \frac{q_{\text{in}}}{c_p}, \quad T_{13} = T_{12} \left( \frac{1}{r_p} \right)^{(k-1)/k}$$

The simultaneous solution of above equations using EES software gives the following results

$$T_7 = 556.7 \text{ K}, \quad T_8 = 855.2 \text{ K}, \quad T_9 = 575.5 \text{ K}$$

$$T_{10} = 874.0 \text{ K}, \quad T_{11} = 588.2 \text{ K}, \quad T_{12} = 886.7 \text{ K}, \quad T_{13} = 596.7 \text{ K}$$

From an energy balance on the regenerator,

$$T_7 - T_6 = T_{13} - T_{14}$$

$$(T_{13} - 40) - T_6 = T_{13} - T_{14} \longrightarrow T_{14} = T_6 + 40 = 430.9 + 40 = 470.9 \text{ K}$$

The heat input is

$$q_{\text{in}} = 300 + 300 + 300 = 900 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p (T_{14} - T_1) + c_p (T_2 - T_3) + c_p (T_4 - T_5) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(470.9 - 290 + 430.9 - 290 + 430.9 - 290) \text{ K} \\ &= 465.0 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{465.0}{900} = \mathbf{0.483}$$

## **Jet-Propulsion Cycles**

**9-138C** The power developed from the thrust of the engine is called the propulsive power. It is equal to thrust times the aircraft velocity.

**9-139C** The ratio of the propulsive power developed and the rate of heat input is called the propulsive efficiency. It is determined by calculating these two quantities separately, and taking their ratio.

**9-140C** It reduces the exit velocity, and thus the thrust.

**9-141E** A turboprop engine operating on an ideal cycle is considered. The thrust force generated is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$  (Table A-1E),  $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working across the two isentropic processes of the cycle yields

$$T_2 = T_1 r_p^{(k-1)/k} = (450 \text{ R})(10)^{0.4/1.4} = 868.8 \text{ R}$$

$$T_5 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1400 \text{ R}) \left( \frac{1}{10} \right)^{0.4/1.4} = 725.1 \text{ R}$$

Since the work produced by expansion 3-4 equals that used by compression 1-2, an energy balance gives

$$T_4 = T_3 - (T_2 - T_1) = 1400 - (868.8 - 450) = 981.2 \text{ R}$$

The excess enthalpy generated by expansion 4-5 is used to increase the kinetic energy of the flow through the propeller,

$$\dot{m}_e c_p (T_4 - T_5) = \dot{m}_p \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

which when solved for the velocity at which the air leaves the propeller gives

$$\begin{aligned} V_{\text{exit}} &= \left[ 2 \frac{\dot{m}_e}{\dot{m}_p} c_p (T_4 - T_5) + V_{\text{inlet}}^2 \right]^{1/2} \\ &= \left[ 2 \frac{1}{20} (0.24 \text{ Btu/lbm}\cdot\text{R})(981.2 - 725.1) \text{ R} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) + (600 \text{ ft/s})^2 \right]^{1/2} \\ &= 716.9 \text{ ft/s} \end{aligned}$$

The mass flow rate through the propeller is

$$\begin{aligned} \nu_1 &= \frac{RT}{P} = \frac{(0.3704 \text{ psia}\cdot\text{ft}^3)(450 \text{ R})}{8 \text{ psia}} = 20.84 \text{ ft}^3/\text{lbm} \\ \dot{m}_p &= \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi (10 \text{ ft})^2}{4} \frac{600 \text{ ft/s}}{20.84 \text{ ft}^3/\text{lbm}} = 2261 \text{ lbm/s} \end{aligned}$$

The thrust force generated by this propeller is then

$$F = \dot{m}_p (V_{\text{exit}} - V_{\text{inlet}}) = (2261 \text{ lbm/s})(716.9 - 600) \text{ ft/s} \left( \frac{1 \text{ lbf}}{32.174 \text{ lbm}\cdot\text{ft/s}^2} \right) = \mathbf{8215 \text{ lbf}}$$

**9-142E** A turboprop engine operating on an ideal cycle is considered. The thrust force generated is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$  (Table A-1E),  $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working across the two isentropic processes of the cycle yields

$$T_2 = T_1 r_p^{(k-1)/k} = (450 \text{ R})(10)^{0.4/1.4} = 868.8 \text{ R}$$

$$T_5 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1400 \text{ R}) \left( \frac{1}{10} \right)^{0.4/1.4} = 725.1 \text{ R}$$

Since the work produced by expansion 3-4 equals that used by compression 1-2, an energy balance gives

$$T_4 = T_3 - (T_2 - T_1) = 1400 - (868.8 - 450) = 981.2 \text{ R}$$

The mass flow rate through the propeller is

$$\nu_1 = \frac{RT}{P} = \frac{(0.3704 \text{ psia}\cdot\text{ft}^3)(450 \text{ R})}{8 \text{ psia}} = 20.84 \text{ ft}^3/\text{lbm}$$

$$\dot{m}_p = \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi (8 \text{ ft})^2}{4} \frac{600 \text{ ft/s}}{20.84 \text{ ft}^3/\text{lbm}} = 1447 \text{ lbm/s}$$

According to the previous problem,

$$\dot{m}_e = \frac{\dot{m}_p}{20} = \frac{2261 \text{ lbm/s}}{20} = 113.1 \text{ lbm/s}$$

The excess enthalpy generated by expansion 4-5 is used to increase the kinetic energy of the flow through the propeller,

$$\dot{m}_e c_p (T_4 - T_5) = \dot{m}_p \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

which when solved for the velocity at which the air leaves the propeller gives

$$\begin{aligned} V_{\text{exit}} &= \left[ 2 \frac{\dot{m}_e}{\dot{m}_p} c_p (T_4 - T_5) + V_{\text{inlet}}^2 \right]^{1/2} \\ &= \left[ 2 \frac{113.1 \text{ lbm/s}}{1447 \text{ lbm/s}} (0.24 \text{ Btu/lbm}\cdot\text{R})(981.2 - 725.1) \text{ R} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) + (600 \text{ ft/s})^2 \right]^{1/2} \\ &= 775.0 \text{ ft/s} \end{aligned}$$

The thrust force generated by this propeller is then

$$F = \dot{m}_p (V_{\text{exit}} - V_{\text{inlet}}) = (1447 \text{ lbm/s})(775 - 600) \text{ ft/s} \left( \frac{1 \text{ lbf}}{32.174 \text{ lbm}\cdot\text{ft/s}^2} \right) = \mathbf{7870 \text{ lbf}}$$

**9-143** A turbofan engine operating on an ideal cycle produces 50,000 N of thrust. The air temperature at the fan outlet needed to produce this thrust is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The total mass flow rate is

$$\nu_1 = \frac{RT}{P} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3)(253 \text{ K})}{50 \text{ kPa}} = 1.452 \text{ m}^3/\text{kg}$$

$$\dot{m} = \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi (2.5 \text{ m})^2}{4} \frac{200 \text{ m/s}}{1.452 \text{ m}^3/\text{kg}} = 676.1 \text{ kg/s}$$

Now,

$$\dot{m}_e = \frac{\dot{m}}{8} = \frac{676.1 \text{ kg/s}}{8} = 84.51 \text{ kg/s}$$

The mass flow rate through the fan is

$$\dot{m}_f = \dot{m} - \dot{m}_e = 676.1 - 84.51 = 591.6 \text{ kg/s}$$

In order to produce the specified thrust force, the velocity at the fan exit will be

$$F = \dot{m}_f (V_{\text{exit}} - V_{\text{inlet}})$$

$$V_{\text{exit}} = V_{\text{inlet}} + \frac{F}{\dot{m}_f} = (200 \text{ m/s}) + \frac{50,000 \text{ N}}{591.6 \text{ kg/s}} \left( \frac{1 \text{ kg} \cdot \text{m/s}^2}{1 \text{ N}} \right) = 284.5 \text{ m/s}$$

An energy balance on the stream passing through the fan gives

$$c_p (T_4 - T_5) = \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

$$T_5 = T_4 - \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2c_p}$$

$$= 253 \text{ K} - \frac{(284.5 \text{ m/s})^2 - (200 \text{ m/s})^2}{2(1.005 \text{ kJ/kg} \cdot \text{K})} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$= \mathbf{232.6 \text{ K}}$$

**9-144** A pure jet engine operating on an ideal cycle is considered. The velocity at the nozzle exit and the thrust produced are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** Working across the two isentropic processes of the cycle yields

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(10)^{0.4/1.4} = 527.1 \text{ K}$$

$$T_5 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (723 \text{ K}) \left( \frac{1}{10} \right)^{0.4/1.4} = 374.5 \text{ K}$$

Since the work produced by expansion 3-4 equals that used by compression 1-2, an energy balance gives

$$T_4 = T_3 - (T_2 - T_1) = 723 - (527.1 - 273) = 468.9 \text{ K}$$

The excess enthalpy generated by expansion 4-5 is used to increase the kinetic energy of the flow through the propeller,

$$c_p (T_4 - T_5) = \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

which when solved for the velocity at which the air leaves the propeller gives

$$\begin{aligned} V_{\text{exit}} &= \left[ 2c_p (T_4 - T_5) + V_{\text{inlet}}^2 \right]^{1/2} \\ &= \left[ 2(1.005 \text{ kJ/kg} \cdot \text{K})(468.9 - 374.5) \text{ K} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) + (300 \text{ m/s})^2 \right]^{1/2} \\ &= \mathbf{528.9 \text{ m/s}} \end{aligned}$$

The mass flow rate through the engine is

$$\begin{aligned} \nu_1 &= \frac{RT}{P} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3)(273 \text{ K})}{60 \text{ kPa}} = 1.306 \text{ m}^3/\text{kg} \\ \dot{m} &= \frac{AV_1}{\nu_1} = \frac{\pi D^2 V_1}{4 \nu_1} = \frac{\pi (2 \text{ m})^2}{4} \frac{300 \text{ m/s}}{1.306 \text{ m}^3/\text{kg}} = 721.7 \text{ kg/s} \end{aligned}$$

The thrust force generated is then

$$F = \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) = (721.7 \text{ kg/s})(528.9 - 300) \text{ m/s} \left( \frac{1 \text{ N}}{1 \text{ kg} \cdot \text{m/s}^2} \right) = \mathbf{165,200 \text{ N}}$$

**9-145** A turbojet aircraft flying at an altitude of 9150 m is operating on the ideal jet propulsion cycle. The velocity of exhaust gases, the propulsive power developed, and the rate of fuel consumption are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit. 5 The turbine work output is equal to the compressor work input.

**Properties** The properties of air at room temperature are  $c_p = 1.005$  kJ/kg·K and  $k = 1.4$  (Table A-2a).

**Analysis** (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of  $V_1 = 320$  m/s. Ideally, the air will leave the diffuser with a negligible velocity ( $V_2 \cong 0$ ).

Diffuser:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\phi 0} \text{ (steady)} \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_1 + V_1^2 / 2 &= h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \\ 0 &= c_p (T_2 - T_1) - V_1^2 / 2 \\ T_2 &= T_1 + \frac{V_1^2}{2c_p} = 241 \text{ K} + \frac{(320 \text{ m/s})^2}{2(1.005 \text{ kJ/kg} \cdot \text{K})} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 291.9 \text{ K} \\ P_2 &= P_1 \left( \frac{T_2}{T_1} \right)^{k/(k-1)} = (32 \text{ kPa}) \left( \frac{291.9 \text{ K}}{241 \text{ K}} \right)^{1.4/0.4} = 62.6 \text{ kPa}\end{aligned}$$

Compressor:

$$\begin{aligned}P_3 &= P_4 = (r_p)(P_2) = (12)(62.6 \text{ kPa}) = 751.2 \text{ kPa} \\ T_3 &= T_2 \left( \frac{P_3}{P_2} \right)^{(k-1)/k} = (291.9 \text{ K})(12)^{0.4/1.4} = 593.7 \text{ K}\end{aligned}$$

Turbine:

**9-149** Air enters a turbojet engine. The thrust produced by this turbojet engine is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with variable specific heats. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit.

**Properties** The properties of air are given in Table A-17.

**Analysis** We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of  $V_1 = 300$  m/s. Taking the entire engine as our control volume and writing the steady-flow energy balance yield

$$T_1 = 280 \text{ K} \longrightarrow h_1 = 280.13 \text{ kJ/kg}$$

$$T_2 = 700 \text{ K} \longrightarrow h_2 = 713.27 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \quad \phi^0 \text{ (steady)}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}(h_1 + V_1^2 / 2) = \dot{m}(h_2 + V_2^2 / 2)$$

$$\dot{Q}_{\text{in}} = \dot{m} \left( h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \right)$$

$$15,000 \text{ kJ/s} = (16 \text{ kg/s}) \left[ 713.27 - 280.13 + \frac{V_2^2 - (300 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right]$$

It gives

$$V_2 = 1048 \text{ m/s}$$

Thus,

$$F_p = \dot{m}(V_2 - V_1) = (16 \text{ kg/s})(1048 - 300) \text{ m/s} = \mathbf{11,968 \text{ N}}$$

## Second-Law Analysis of Gas Power Cycles

**9-150E** The exergy destruction associated with the heat rejection process of the Diesel cycle described in Prob. 9-60 and the exergy at the end of the expansion stroke are to be determined.

**Analysis** From Prob. 9-60E,  $q_{\text{out}} = 158.9 \text{ Btu/lbm}$ ,  $T_1 = 540 \text{ R}$ ,  $T_4 = 1420.6 \text{ R}$ , and  $\nu_4 = \nu_1$ . At  $T_{\text{avg}} = (T_4 + T_1)/2 = (1420.6 + 540)/2 = 980.3 \text{ R}$ , we have  $c_{\nu, \text{avg}} = 0.180 \text{ Btu/lbm} \cdot \text{R}$ . The entropy change during process 4-1 is

$$s_1 - s_4 = c_{\nu} \ln \frac{T_1}{T_4} + R \ln \frac{\nu_1}{\nu_4} \stackrel{\circ}{=} (0.180 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{540 \text{ R}}{1420.6 \text{ R}} = -0.1741 \text{ Btu/lbm} \cdot \text{R}$$

Thus,

$$x_{\text{destroyed}, 41} = T_0 \left( s_1 - s_4 + \frac{q_{R, 41}}{T_R} \right) = (540 \text{ R}) \left( -0.1741 \text{ Btu/lbm} \cdot \text{R} + \frac{158.9 \text{ Btu/lbm}}{540 \text{ R}} \right) = \mathbf{64.9 \text{ Btu/lbm}}$$

Noting that state 4 is identical to the state of the surroundings, the exergy at the end of the power stroke (state 4) is determined from

$$\phi_4 = (u_4 - u_0) - T_0 (s_4 - s_0) + P_0 (\nu_4 - \nu_0)$$

where

$$u_4 - u_0 = u_4 - u_1 = q_{\text{out}} = 158.9 \text{ Btu/lbm} \cdot \text{R}$$

$$\nu_4 - \nu_0 = \nu_4 - \nu_1 = 0$$

$$s_4 - s_0 = s_4 - s_1 = 0.1741 \text{ Btu/lbm} \cdot \text{R}$$

Thus,

$$\phi_4 = (158.9 \text{ Btu/lbm}) - (540 \text{ R})(0.1741 \text{ Btu/lbm} \cdot \text{R}) + 0 = \mathbf{64.9 \text{ Btu/lbm}}$$

**Discussion** Note that the exergy at state 4 is identical to the exergy destruction for the process 4-1 since state 1 is identical to the dead state, and the entire exergy at state 4 is wasted during process 4-1.

**9-151** The exergy destruction associated with each of the processes of the Brayton cycle described in Prob. 9-91 is to be determined.

**Analysis** From Prob. 9-91,  $q_{\text{in}} = 584.62 \text{ kJ/kg}$ ,  $q_{\text{out}} = 478.92 \text{ kJ/kg}$ , and

$$T_1 = 310 \text{ K} \longrightarrow s_1^\circ = 1.73498 \text{ kJ/kg} \cdot \text{K}$$

$$h_2 = 646.3 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.47256 \text{ kJ/kg} \cdot \text{K}$$

$$T_3 = 1160 \text{ K} \longrightarrow s_3^\circ = 3.13916 \text{ kJ/kg} \cdot \text{K}$$

$$h_4 = 789.16 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.67602 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$\begin{aligned} x_{\text{destroyed},12} &= T_0 s_{\text{gen},12} = T_0 (s_2 - s_1) = T_0 \left( s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) = \\ &= (310 \text{ K}) (2.47256 - 1.73498 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(8)) = \mathbf{43.6 \text{ kJ/kg}} \\ x_{\text{destroyed},23} &= T_0 s_{\text{gen},23} = T_0 \left( s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = T_0 \left( s_3^\circ - s_2^\circ - R \ln \frac{P_3}{P_2} \overset{\phi_0}{+} \frac{-q_{\text{in}}}{T_H} \right) \\ &= (310 \text{ K}) \left( 3.13916 - 2.47256 - \frac{584.62 \text{ kJ/kg}}{1600 \text{ K}} \right) = \mathbf{93.4 \text{ kJ/kg}} \\ x_{\text{destroyed},34} &= T_0 s_{\text{gen},34} = T_0 (s_4 - s_3) = T_0 \left( s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) = \\ &= (310 \text{ K}) (2.67602 - 3.13916 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(1/8)) = \mathbf{41.4 \text{ kJ/kg}} \\ x_{\text{destroyed},41} &= T_0 s_{\text{gen},41} = T_0 \left( s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = T_0 \left( s_1^\circ - s_4^\circ - R \ln \frac{P_1}{P_4} \overset{\phi_0}{+} \frac{q_{\text{out}}}{T_L} \right) \\ &= (310 \text{ K}) \left( 1.73498 - 2.67602 + \frac{478.92 \text{ kJ/kg}}{310 \text{ K}} \right) = \mathbf{220 \text{ kJ/kg}} \end{aligned}$$

**9-152E** The exergy loss of an ideal dual cycle described in Prob. 9-58E is to be determined.

**Analysis** From Prob. 9-58E,  $q_{\text{out}} = 66.48 \text{ Btu/lbm}$ ,  $T_1 = 530 \text{ R}$ ,  $T_2 = 1757 \text{ R}$ ,  $T_x = 2109 \text{ R}$ ,  $T_3 = 2742 \text{ R}$ , and  $T_4 = 918.8 \text{ R}$ . Also,

$$q_{\text{in},2-x} = c_v(T_x - T_2) = (0.171 \text{ Btu/lbm} \cdot \text{R})(2109 - 1757)\text{R} = 60.19 \text{ Btu/lbm}$$

$$q_{\text{in},x-3} = c_v(T_3 - T_x) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2742 - 2109)\text{R} = 151.9 \text{ Btu/lbm}$$

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg} \cdot \text{K})(494.8 - 291)\text{K} = 146.3 \text{ kJ/kg}$$

The exergy destruction during a process of the cycle is

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( \Delta s - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{dest},1-2} = 0 \quad (\text{isentropic process})$$

$$s_x - s_2 = c_v \ln \frac{T_x}{T_2} + R \ln \frac{v_x}{v_2}$$

$$= (0.171 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{2109 \text{ R}}{1757 \text{ R}} + 0 = 0.03123 \text{ Btu/lbm} \cdot \text{R}$$

$$x_{\text{dest},2-x} = T_0 \left( s_x - s_2 - \frac{q_{\text{in},2-x}}{T_{\text{source}}} \right) = (530 \text{ R}) \left( 0.03123 \text{ Btu/lbm} \cdot \text{R} - \frac{60.19 \text{ Btu/lbm}}{2742 \text{ R}} \right) = 4.917 \text{ Btu/lbm}$$

$$s_3 - s_x = c_p \ln \frac{T_3}{T_x} - R \ln \frac{P_3}{P_x} = (0.240 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{2742 \text{ R}}{2109 \text{ R}} - 0 = 0.06299 \text{ Btu/lbm} \cdot \text{R}$$

$$x_{\text{dest},x-3} = T_0 \left( s_3 - s_x - \frac{q_{\text{in},x-3}}{T_{\text{source}}} \right) = (530 \text{ R}) \left( 0.06299 \text{ Btu/lbm} \cdot \text{R} - \frac{151.9 \text{ Btu/lbm}}{2742 \text{ R}} \right) = 4.024 \text{ Btu/lbm}$$

$$x_{\text{dest},3-4} = 0 \quad (\text{isentropic process})$$

$$s_1 - s_4 = c_v \ln \frac{T_1}{T_4} + R \ln \frac{v_1}{v_4} = (0.171 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{530 \text{ R}}{918.8 \text{ R}} + 0 = -0.09408 \text{ Btu/lbm} \cdot \text{R}$$

$$x_{\text{dest},4-1} = T_0 \left( s_1 - s_4 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (530 \text{ R}) \left( -0.09408 \text{ Btu/lbm} \cdot \text{R} + \frac{66.48 \text{ Btu/lbm}}{530 \text{ R}} \right) = 16.62 \text{ Btu/lbm}$$

The largest exergy destruction in the cycle occurs during the heat-rejection process

s. The total exergy destruction in the cycle is

$$x_{\text{dest,total}} = 4.917 + 4.024 + 16.62 = \mathbf{25.6 \text{ Btu/lbm}}$$

**9-153E** The entropy generated by the Brayton cycle of Prob. 9-102E is to be determined.

**Analysis** From Prob. 9-102E,

$$\dot{Q}_{\text{in}} = 2356 \text{ Btu/s}$$

$$\dot{Q}_{\text{out}} = \dot{Q}_{\text{in}} - \dot{W}_{\text{net}} = 2356 - 1417 = 939 \text{ Btu/s}$$

$$T_H = 1660 \text{ R}$$

$$T_L = 540 \text{ R}$$

No entropy is generated by the working fluid since it always returns to its original state. Then,

$$\dot{S}_{\text{gen}} = \frac{\dot{Q}_{\text{out}}}{T_L} - \frac{\dot{Q}_{\text{in}}}{T_H} = \frac{939 \text{ Btu/s}}{540 \text{ R}} - \frac{2356 \text{ Btu/s}}{1660 \text{ R}} = \mathbf{0.320 \text{ Btu/s} \cdot \text{R}}$$

**9-154** The exergy loss of each process for a regenerative Brayton cycle described in Prob. 9-112 is to be determined.

**Analysis** From Prob. 9-112,  $T_1 = 293 \text{ K}$ ,  $T_2 = 566.3 \text{ K}$ ,  $T_3 = 1073 \text{ K}$ ,  $T_4 = 625.9 \text{ K}$ ,  $T_5 = 615.9 \text{ K}$ ,  $T_6 = 576.3 \text{ K}$ , and  $r_p = 8$ .

Also,

$$q_{\text{in}} = c_p (T_3 - T_5) = (1.005 \text{ kJ/kg} \cdot \text{K})(1073 - 615.9) \text{ K} = 659.4 \text{ kJ/kg}$$

$$q_{\text{out}} = c_p (T_6 - T_1) = (1.005 \text{ kJ/kg} \cdot \text{K})(576.3 - 293) \text{ K} = 284.7 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{dest}, 1-2} = T_0 \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) = (293) \left[ (1.005) \ln \frac{566.3}{293} - (0.287) \ln(8) \right] = \mathbf{19.2 \text{ kJ/kg}}$$

$$x_{\text{dest}, 5-3} = T_0 \left( c_p \ln \frac{T_3}{T_5} - R \ln \frac{P_3}{P_5} - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (293) \left[ (1.005) \ln \frac{1073}{615.9} - 0 - \frac{459.4}{1073} \right] = \mathbf{38.0 \text{ kJ/kg}}$$

$$x_{\text{dest}, 3-4} = T_0 \left( c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} \right) = (293 \text{ K}) \left[ (1.005) \ln \frac{625.9}{1073} - (0.287) \ln \left( \frac{1}{8} \right) \right] = \mathbf{16.1 \text{ kJ/kg}}$$

$$x_{\text{dest}, 6-1} = T_0 \left( c_p \ln \frac{T_1}{T_6} - R \ln \frac{P_1}{P_6} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (293) \left[ (1.005) \ln \frac{293}{576.3} - 0 + \frac{284.7}{293} \right] = \mathbf{85.5 \text{ kJ/kg}}$$

$$\begin{aligned} x_{\text{dest}, \text{regen}} &= T_0 (\Delta s_{2-5} + \Delta s_{4-6}) = T_0 \left( c_p \ln \frac{T_5}{T_2} + c_p \ln \frac{T_6}{T_4} \right) \\ &= (293) \left[ (1.005) \ln \frac{615.9}{566.3} + (1.005) \ln \frac{576.3}{625.9} \right] = \mathbf{0.41 \text{ kJ/kg}} \end{aligned}$$

**9-155** The total exergy destruction associated with the Brayton cycle described in Prob. 9-119 and the exergy at the exhaust gases at the turbine exit are to be determined.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1).

**Analysis** From Prob. 9-119,  $q_{\text{in}} = 480.82$ ,  $q_{\text{out}} = 372.73 \text{ kJ/kg}$ , and

$$T_1 = 310 \text{ K} \longrightarrow s_1^\circ = 1.73498 \text{ kJ/kg} \cdot \text{K}$$

$$h_2 = 618.26 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.42763 \text{ kJ/kg} \cdot \text{K}$$

$$T_3 = 1150 \text{ K} \longrightarrow s_3^\circ = 3.12900 \text{ kJ/kg} \cdot \text{K}$$

$$h_4 = 803.14 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.69407 \text{ kJ/kg} \cdot \text{K}$$

$$h_5 = 738.43 \text{ kJ/kg} \longrightarrow s_5^\circ = 2.60815 \text{ kJ/kg} \cdot \text{K}$$

and, from an energy balance on the heat exchanger,

$$h_5 - h_2 = h_4 - h_6 \longrightarrow h_6 = 803.14 - (738.43 - 618.26) = 682.97 \text{ kJ/kg}$$

$$\longrightarrow s_6^\circ = 2.52861 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$\begin{aligned} x_{\text{destroyed},12} &= T_0 s_{\text{gen},12} = T_0 (s_2 - s_1) = T_0 \left( s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) \\ &= (310 \text{ K}) (2.42763 - 1.73498 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(7)) = \mathbf{41.59 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},34} &= T_0 s_{\text{gen},34} = T_0 (s_4 - s_3) = T_0 \left( s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) \\ &= (310 \text{ K}) (2.69407 - 3.12900 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(1/7)) = \mathbf{38.30 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed,regen}} &= T_0 s_{\text{gen,regen}} = T_0 [(s_5 - s_2) + (s_6 - s_4)] = T_0 [(s_5^\circ - s_2^\circ) + (s_6^\circ - s_4^\circ)] \\ &= (310 \text{ K}) (2.60815 - 2.42763 + 2.52861 - 2.69407) = \mathbf{4.67 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},53} &= T_0 s_{\text{gen},53} = T_0 \left( s_3 - s_5 - \frac{q_{R,53}}{T_R} \right) = T_0 \left( s_3^\circ - s_5^\circ - R \ln \frac{P_3}{P_5} - \frac{q_{\text{in}}}{T_H} \right) \\ &= (310 \text{ K}) \left( 3.12900 - 2.60815 - \frac{480.82 \text{ kJ/kg}}{1800 \text{ K}} \right) = \mathbf{78.66 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},61} &= T_0 s_{\text{gen},61} = T_0 \left( s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = T_0 \left( s_1^\circ - s_6^\circ - R \ln \frac{P_1}{P_6} + \frac{q_{\text{out}}}{T_L} \right) \\ &= (310 \text{ K}) \left( 1.73498 - 2.52861 + \frac{372.73 \text{ kJ/kg}}{310 \text{ K}} \right) = \mathbf{126.7 \text{ kJ/kg}} \end{aligned}$$

Noting that  $h_0 = h_{@ 310 \text{ K}} = 310.24 \text{ kJ/kg}$ , the stream exergy at the exit of the regenerator (state 6) is determined from

$$\phi_6 = (h_6 - h_0) - T_0 (s_6 - s_0) + \frac{V_6^2}{2} + gz_6$$

$$\text{where } s_6 - s_0 = s_6 - s_1 = s_6^\circ - s_1^\circ - R \ln \frac{P_6}{P_1} = 2.52861 - 1.73498 = 0.79363 \text{ kJ/kg} \cdot \text{K}$$

$$\text{Thus, } \phi_6 = 682.97 - 310.24 - (310 \text{ K})(0.79363 \text{ kJ/kg} \cdot \text{K}) = \mathbf{126.7 \text{ kJ/kg}}$$

**9-156 EES** Prob. 9-155 is reconsidered. The effect of the cycle pressure on the total irreversibility for the cycle and the exergy of the exhaust gas leaving the regenerator is to be investigated.

**Analysis** Using EES, the problem is solved as follows:

**9-157E** The exergy loss of each process for a reheat-regenerative Brayton cycle with intercooling described in Prob. 9-134E is to be determined.

**Analysis** From Prob. 9-134E,

$$T_1 = T_3 = 520 \text{ R},$$

$$T_2 = T_4 = T_{10} = 737.8 \text{ R},$$

$$T_5 = T_7 = T_9 = 1049 \text{ K},$$

$$T_6 = T_8 = 1400 \text{ R}, \text{ and } r_p = 3.$$

Also,

$$\begin{aligned} q_{\text{in},5-6} &= q_{\text{in},7-8} = c_p (T_6 - T_5) \\ &= (0.240 \text{ Btu/lbm} \cdot \text{R})(1400 - 1049) \text{ R} = 84.24 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned} q_{\text{out},10-1} &= q_{\text{out},2-3} = c_p (T_{10} - T_1) \\ &= (0.240 \text{ Btu/lbm} \cdot \text{R})(737.8 - 520) \text{ R} = 52.27 \text{ Btu/lbm} \end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{dest},1-2} = x_{\text{dest},3-4} = T_0 \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) = (520) \left[ (0.24) \ln \frac{737.8}{520} - (0.06855) \ln(3) \right] = 4.50 \text{ Btu/lbm}$$

$$x_{\text{dest},5-6} = x_{\text{dest},7-8} = T_0 \left( c_p \ln \frac{T_6}{T_5} - R \ln \frac{P_6}{P_5} - \frac{q_{\text{in},5-6}}{T_{\text{source}}} \right) = (520) \left[ (0.24) \ln \frac{1400}{1049} - 0 - \frac{84.24}{1400} \right] = 4.73 \text{ Btu/lbm}$$

$$x_{\text{dest},6-7} = x_{\text{dest},8-9} = T_0 \left( c_p \ln \frac{T_7}{T_6} - R \ln \frac{P_7}{P_6} \right) = (520) \left[ (0.24) \ln \frac{1049}{1400} - (0.06855) \ln \left( \frac{1}{3} \right) \right] = 3.14 \text{ Btu/lbm}$$

$$x_{\text{dest},10-1} = x_{\text{dest},2-3} = T_0 \left( c_p \ln \frac{T_1}{T_{10}} - R \ln \frac{P_1}{P_{10}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (520) \left[ (0.24) \ln \frac{520}{737.8} - 0 + \frac{52.27}{520} \right] = 8.61 \text{ Btu/lbm}$$

$$\begin{aligned} x_{\text{dest,regen}} &= T_0 (\Delta s_{4-5} + \Delta s_{9-10}) = T_0 \left( c_p \ln \frac{T_5}{T_4} + c_p \ln \frac{T_{10}}{T_9} \right) \\ &= (520) \left[ (0.24) \ln \frac{1049}{737.8} + (0.24) \ln \frac{737.8}{1049} \right] = 0 \text{ Btu/lbm} \end{aligned}$$

The greatest exergy destruction occurs during the heat rejection processes.

**9-158** The exergy loss of each process for a regenerative Brayton cycle with three stages of reheating and intercooling described in Prob. 9-137 is to be determined.

**Analysis** From Prob. 9-137,

$$\begin{aligned} r_p &= 4, \quad q_{\text{in},7-8} = q_{\text{in},9-10} = q_{\text{in},11-12} = 300 \text{ kJ/kg}, \\ q_{\text{out},14-1} &= 181.8 \text{ kJ/kg}, \quad q_{\text{out},2-3} = q_{\text{out},4-5} = 141.6 \text{ kJ/kg}, \\ T_1 &= T_3 = T_5 = 290 \text{ K}, \quad T_2 = T_4 = T_6 = 430.9 \text{ K} \\ T_7 &= 556.7 \text{ K}, \quad T_8 = 855.2 \text{ K}, \quad T_9 = 575.5 \text{ K} \\ T_{10} &= 874.0 \text{ K}, \quad T_{11} = 588.2 \text{ K}, \quad T_{12} = 886.7 \text{ K}, \\ T_{13} &= 596.7 \text{ K}, \quad T_{14} = 470.9 \text{ K} \end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} x_{\text{dest},1-2} &= x_{\text{dest},3-4} = x_{\text{dest},5-6} = T_0 \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) \\ &= (290) \left[ (1.005) \ln \frac{430.9}{290} - (0.287) \ln(4) \right] = \mathbf{0.03 \text{ kJ/kg} \approx 0} \end{aligned}$$

$$x_{\text{dest},7-8} = T_0 \left( c_p \ln \frac{T_8}{T_7} - R \ln \frac{P_8}{P_7} - \frac{q_{\text{in},7-8}}{T_{\text{source}}} \right) = (290) \left[ (1.005) \ln \frac{855.2}{556.7} - 0 - \frac{300}{886.7} \right] = \mathbf{27.0 \text{ kJ/kg}}$$

$$x_{\text{dest},9-10} = T_0 \left( c_p \ln \frac{T_{10}}{T_9} - R \ln \frac{P_{10}}{P_9} - \frac{q_{\text{in},9-10}}{T_{\text{source}}} \right) = (290) \left[ (1.005) \ln \frac{874.0}{575.5} - 0 - \frac{300}{886.7} \right] = \mathbf{23.7 \text{ kJ/kg}}$$

$$x_{\text{dest},11-12} = T_0 \left( c_p \ln \frac{T_{12}}{T_{11}} - R \ln \frac{P_{12}}{P_{11}} - \frac{q_{\text{in},11-12}}{T_{\text{source}}} \right) = (290) \left[ (1.005) \ln \frac{886.7}{588.2} - 0 - \frac{300}{886.7} \right] = \mathbf{21.5 \text{ kJ/kg}}$$

$$x_{\text{dest},8-9} = T_0 \left( c_p \ln \frac{T_9}{T_8} - R \ln \frac{P_9}{P_8} \right) = (290) \left[ (1.005) \ln \frac{575.5}{855.2} - (0.287) \ln \left( \frac{1}{4} \right) \right] = \mathbf{-0.06 \text{ kJ/kg} \approx 0}$$

$$x_{\text{dest},10-11} = T_0 \left( c_p \ln \frac{T_{11}}{T_{10}} - R \ln \frac{P_{11}}{P_{10}} \right) = (290) \left[ (1.005) \ln \frac{588.2}{874.0} - (0.287) \ln \left( \frac{1}{4} \right) \right] = \mathbf{0.42 \text{ kJ/kg} \approx 0}$$

$$x_{\text{dest},12-13} = T_0 \left( c_p \ln \frac{T_{13}}{T_{12}} - R \ln \frac{P_{13}}{P_{12}} \right) = (290) \left[ (1.005) \ln \frac{596.7}{886.7} - (0.287) \ln \left( \frac{1}{4} \right) \right] = \mathbf{-0.05 \text{ kJ/kg} \approx 0}$$

$$x_{\text{dest},14-1} = T_0 \left( c_p \ln \frac{T_1}{T_{14}} - R \ln \frac{P_1}{P_{14}} + \frac{q_{\text{out},14-1}}{T_{\text{sink}}} \right) = (290) \left[ (1.005) \ln \frac{290}{470.9} - 0 + \frac{181.8}{290} \right] = \mathbf{40.5 \text{ kJ/kg}}$$

$$x_{\text{dest},2-3} = x_{\text{dest},4-5} = T_0 \left( c_p \ln \frac{T_3}{T_2} - R \ln \frac{P_3}{P_2} + \frac{q_{\text{out},2-3}}{T_{\text{sink}}} \right) = (290) \left[ (1.005) \ln \frac{290}{430.9} - 0 + \frac{141.6}{290} \right] = \mathbf{26.2 \text{ kJ/kg}}$$

$$\begin{aligned} x_{\text{dest,regen}} &= T_0 (\Delta s_{6-7} + \Delta s_{13-14}) = T_0 \left( c_p \ln \frac{T_7}{T_6} + c_p \ln \frac{T_{14}}{T_{13}} \right) \\ &= (290) \left[ (1.005) \ln \frac{556.7}{430.9} + (1.005) \ln \frac{470.9}{596.7} \right] = \mathbf{5.65 \text{ kJ/kg}} \end{aligned}$$

**9-159** A gas-turbine plant uses diesel fuel and operates on simple Brayton cycle. The isentropic efficiency of the compressor, the net power output, the back work ratio, the thermal efficiency, and the second-law efficiency are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at  $500^\circ\text{C} = 773\text{ K}$  are  $c_p = 1.093\text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.806\text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287\text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.357$  (Table A-2b).

**Analysis (a)** The isentropic efficiency of the compressor may be determined if we first calculate the exit temperature for the isentropic case

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (303\text{ K}) \left( \frac{700\text{ kPa}}{100\text{ kPa}} \right)^{(1.357-1)/1.357} = 505.6\text{ K}$$

$$\eta_C = \frac{T_{2s} - T_1}{T_2 - T_1} = \frac{(505.6 - 303)\text{ K}}{(533 - 303)\text{ K}} = \mathbf{0.881}$$

(b) The total mass flowing through the turbine and the rate of heat input are

$$\dot{m}_t = \dot{m}_a + \dot{m}_f = \dot{m}_a + \frac{\dot{m}_a}{\text{AF}} = 12.6\text{ kg/s} + \frac{12.6\text{ kg/s}}{60} = 12.6\text{ kg/s} + 0.21\text{ kg/s} = 12.81\text{ kg/s}$$

$$\dot{Q}_{\text{in}} = \dot{m}_f q_{\text{HV}} \eta_c = (0.21\text{ kg/s})(42,000\text{ kJ/kg})(0.97) = 8555\text{ kW}$$

The temperature at the exit of combustion chamber is

$$\dot{Q}_{\text{in}} = \dot{m}_c p (T_3 - T_2) \longrightarrow 8555\text{ kJ/s} = (12.81\text{ kg/s})(1.093\text{ kJ/kg}\cdot\text{K})(T_3 - 533)\text{ K} \longrightarrow T_3 = 1144\text{ K}$$

The temperature at the turbine exit is determined using isentropic efficiency relation

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1144\text{ K}) \left( \frac{100\text{ kPa}}{700\text{ kPa}} \right)^{(1.357-1)/1.357} = 685.7\text{ K}$$

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow 0.85 = \frac{(1144 - T_4)\text{ K}}{(1144 - 685.7)\text{ K}} \longrightarrow T_4 = 754.4\text{ K}$$

The net power and the back work ratio are

$$\dot{W}_{\text{C,in}} = \dot{m}_a c_p (T_2 - T_1) = (12.6\text{ kg/s})(1.093\text{ kJ/kg}\cdot\text{K})(533 - 303)\text{ K} = 3168\text{ kW}$$

$$\dot{W}_{\text{T,out}} = \dot{m}_c p (T_3 - T_4) = (12.81\text{ kg/s})(1.093\text{ kJ/kg}\cdot\text{K})(1144 - 754.4)\text{ K} = 5455\text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{\text{T,out}} - \dot{W}_{\text{C,in}} = 5455 - 3168 = \mathbf{2287\text{ kW}}$$

$$r_{\text{bw}} = \frac{\dot{W}_{\text{C,in}}}{\dot{W}_{\text{T,out}}} = \frac{3168\text{ kW}}{5455\text{ kW}} = \mathbf{0.581}$$

(c) The thermal efficiency is  $\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{2287\text{ kW}}{8555\text{ kW}} = \mathbf{0.267}$

The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). The maximum temperature for the cycle can be taken to be the turbine inlet temperature. That is,

$$\eta_{\text{max}} = 1 - \frac{T_1}{T_3} = 1 - \frac{303\text{ K}}{1144\text{ K}} = 0.735$$

$$\text{and } \eta_{\text{II}} = \frac{\eta_{\text{th}}}{\eta_{\text{max}}} = \frac{0.267}{0.735} = \mathbf{0.364}$$

**9-160** A modern compression ignition engine operates on the ideal dual cycle. The maximum temperature in the cycle, the net work output, the thermal efficiency, the mean effective pressure, the net power output, the second-law efficiency of the cycle, and the rate of exergy of the exhaust gases are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at 850 K are  $c_p = 1.110 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.823 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.349$  (Table A-2b).

**Analysis** (a) The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{V_c + V_d}{V_c} \longrightarrow 14 = \frac{V_c + 0.0028 \text{ m}^3}{V_c} \longrightarrow V_c = 0.0002154 \text{ m}^3 = V_2 = V_x$$

$$V_1 = V_c + V_d = 0.0002154 + 0.0028 = 0.003015 \text{ m}^3 = V_4$$

Process 1-2: Isentropic compression

$$T_2 = T_1 \left( \frac{V_1}{V_2} \right)^{k-1} = (328 \text{ K})(14)^{1.349-1} = 823.9 \text{ K}$$

$$P_2 = P_1 \left( \frac{V_1}{V_2} \right)^k = (95 \text{ kPa})(14)^{1.349} = 3341 \text{ kPa}$$

Process 2-x and x-3: Constant-volume and constant pressure heat addition processes:

$$T_x = T_2 \frac{P_x}{P_2} = (823.9 \text{ K}) \frac{9000 \text{ kPa}}{3341 \text{ kPa}} = 2220 \text{ K}$$

$$q_{2-x} = c_v (T_x - T_2) = (0.823 \text{ kJ/kg}\cdot\text{K})(2220 - 823.9) \text{ K} = 1149 \text{ kJ/kg}$$

$$q_{2-x} = q_{x-3} = c_p (T_3 - T_x) \longrightarrow 1149 \text{ kJ/kg} = (0.823 \text{ kJ/kg}\cdot\text{K})(T_3 - 2220) \text{ K} \longrightarrow T_3 = \mathbf{3254 \text{ K}}$$

$$(b) \quad q_{in} = q_{2-x} + q_{x-3} = 1149 + 1149 = 2298 \text{ kJ/kg}$$

$$V_3 = V_x \frac{T_3}{T_x} = (0.0002154 \text{ m}^3) \frac{3254 \text{ K}}{2220 \text{ K}} = 0.0003158 \text{ m}^3$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{V_3}{V_4} \right)^{k-1} = (3254 \text{ K}) \left( \frac{0.0003158 \text{ m}^3}{0.003015 \text{ m}^3} \right)^{1.349-1} = 1481 \text{ K}$$

$$P_4 = P_3 \left( \frac{V_3}{V_4} \right)^k = (9000 \text{ kPa}) \left( \frac{0.0003158 \text{ m}^3}{0.003015 \text{ m}^3} \right)^{1.349} = 428.9 \text{ kPa}$$

Process 4-1: constant volume heat rejection.

$$q_{out} = c_v (T_4 - T_1) = (0.823 \text{ kJ/kg}\cdot\text{K})(1481 - 328) \text{ K} = 948.7 \text{ kJ/kg}$$

The net work output and the thermal efficiency are

$$w_{net,out} = q_{in} - q_{out} = 2298 - 948.7 = \mathbf{1349 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{1349 \text{ kJ/kg}}{2298 \text{ kJ/kg}} = \mathbf{0.587}$$

(c) The mean effective pressure is determined to be

$$m = \frac{P_1 V_1}{RT_1} = \frac{(95 \text{ kPa})(0.003015 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(328 \text{ K})} = 0.003043 \text{ kg}$$

$$\text{MEP} = \frac{mw_{\text{net,out}}}{V_1 - V_2} = \frac{(0.003043 \text{ kg})(1349 \text{ kJ/kg})}{(0.003015 - 0.0002154) \text{ m}^3} \left( \frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = \mathbf{1466 \text{ kPa}}$$

(d) The power for engine speed of 3500 rpm is

$$\dot{W}_{\text{net}} = mw_{\text{net}} \frac{\dot{n}}{2} = (0.003043 \text{ kg})(1349 \text{ kJ/kg}) \frac{3500 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left( \frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{120 \text{ kW}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). We take the dead state temperature and pressure to be 25°C and 100 kPa.

$$\eta_{\text{max}} = 1 - \frac{T_0}{T_3} = 1 - \frac{(25 + 273) \text{ K}}{3254 \text{ K}} = 0.908$$

and

$$\eta_{\text{II}} = \frac{\eta_{\text{th}}}{\eta_{\text{max}}} = \frac{0.587}{0.908} = \mathbf{0.646}$$

The rate of exergy of the exhaust gases is determined as follows

$$x_4 = u_4 - u_0 - T_0(s_4 - s_0) = c_v(T_4 - T_0) - T_0 \left[ c_p \ln \frac{T_4}{T_0} - R \ln \frac{P_4}{P_0} \right]$$

$$= (0.823)(1481 - 298) - (298) \left[ (1.110 \text{ kJ/kg} \cdot \text{K}) \ln \frac{1481}{298} - 0.287 \ln \frac{428.9}{100} \right] = 567.6 \text{ kJ/kg}$$

$$\dot{X}_4 = mx_4 \frac{\dot{n}}{2} = (0.003043 \text{ kg})(567.6 \text{ kJ/kg}) \frac{3500 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left( \frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{50.4 \text{ kW}}$$

## Review Problems

**9-161** A turbocharged four-stroke V-16 diesel engine produces 3500 hp at 1200 rpm. The amount of power produced per cylinder per mechanical and per thermodynamic cycle is to be determined.

**Analysis** Noting that there are 16 cylinders and each thermodynamic cycle corresponds to 2 mechanical cycles (revolutions), we have

(a)

$$\begin{aligned}
 w_{\text{mechanical}} &= \frac{\text{Total power produced}}{(\text{No. of cylinders})(\text{No. of mechanical cycles})} \\
 &= \frac{3500 \text{ hp}}{(16 \text{ cylinders})(1200 \text{ rev/min})} \left( \frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) \\
 &= \mathbf{7.73 \text{ Btu/cyl} \cdot \text{mech cycle}} \quad (= 8.16 \text{ kJ/cyl} \cdot \text{mech cycle})
 \end{aligned}$$

(b)

$$\begin{aligned}
 w_{\text{thermodynamic}} &= \frac{\text{Total power produced}}{(\text{No. of cylinders})(\text{No. of thermodynamic cycles})} \\
 &= \frac{3500 \text{ hp}}{(16 \text{ cylinders})(1200/2 \text{ rev/min})} \left( \frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) \\
 &= \mathbf{15.46 \text{ Btu/cyl} \cdot \text{therm cycle}} \quad (= 16.31 \text{ kJ/cyl} \cdot \text{therm cycle})
 \end{aligned}$$

**9-162** A simple ideal Brayton cycle operating between the specified temperature limits is considered. The pressure ratio for which the compressor and the turbine exit temperature of air are equal is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2).

**Analysis** We treat air as an ideal gas with constant specific heats. Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$\begin{aligned}
 T_2 &= T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k} \\
 T_4 &= T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k}
 \end{aligned}$$

Setting  $T_2 = T_4$  and solving for  $r_p$  gives

$$r_p = \left( \frac{T_3}{T_1} \right)^{k/2(k-1)} = \left( \frac{1500 \text{ K}}{300 \text{ K}} \right)^{1.4/0.8} = \mathbf{16.7}$$

Therefore, the compressor and turbine exit temperatures will be equal when the compression ratio is 16.7.

**9-163** The three processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $\nu$  and  $T$ - $s$  diagrams, and the maximum temperature in the cycle and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis** (b) We treat air as an ideal gas with variable specific heats,

$$T_1 = 300 \text{ K} \longrightarrow u_1 = 214.07 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left( \frac{700 \text{ kPa}}{100 \text{ kPa}} \right) (1.386) = 9.702 \longrightarrow h_2 = 523.90 \text{ kJ/kg}$$

$$\frac{P_3 \nu_3}{T_3} = \frac{P_1 \nu_1}{T_1} \longrightarrow T_{\max} = T_3 = \frac{P_3}{P_1} T_1 = \left( \frac{700 \text{ kPa}}{100 \text{ kPa}} \right) (300 \text{ K}) = \mathbf{2100 \text{ K}}$$

$$T_3 = 2100 \text{ K} \longrightarrow u_3 = 1775.3 \text{ kJ/kg}$$

$$h_3 = 2377.7 \text{ kJ/kg}$$

$$(c) \quad q_{\text{in}} = h_3 - h_2 = 2377.7 - 523.9 = 1853.8 \text{ kJ/kg}$$

$$q_{\text{out}} = u_3 - u_1 = 1775.3 - 214.07 = 1561.23 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1561.23 \text{ kJ/kg}}{1853.8 \text{ kJ/kg}} = \mathbf{15.8\%}$$

**9-164** All three processes of an air-standard cycle are described. The cycle is to be shown on  $P$ - $v$  and  $T$ - $s$  diagrams, and the maximum temperature in the cycle and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (b) We treat air as an ideal gas with constant specific heats.

Process 1-2 is isentropic:

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left( \frac{700 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 523.1 \text{ K}$$

$$\frac{P_3 v_3}{T_3} = \frac{P_1 v_1}{T_1} \longrightarrow T_{\max} = T_3 = \frac{P_3}{P_1} T_1 = \left( \frac{700 \text{ kPa}}{100 \text{ kPa}} \right) (300 \text{ K}) = 2100 \text{ K}$$

$$\begin{aligned} (c) \quad q_{\text{in}} &= h_3 - h_2 = c_p (T_3 - T_2) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(2100 - 523.1) \text{ K} = 1584.8 \text{ kJ/kg} \\ q_{\text{out}} &= u_3 - u_1 = c_v (T_3 - T_1) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(2100 - 300) \text{ K} = 1292.4 \text{ kJ/kg} \\ \eta_{\text{th}} &= 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1292.4 \text{ kJ/kg}}{1584.8 \text{ kJ/kg}} = 18.5\% \end{aligned}$$

**9-165 [Also solved by EES on enclosed CD]** A four-cylinder spark-ignition engine with a compression ratio of 8 is considered. The amount of heat supplied per cylinder, the thermal efficiency, and the rpm for a net power output of 60 kW are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1). The properties of air are given in Table A-17.

**Analysis** (a) Process 1-2: isentropic compression.

$$T_1 = 290 \text{ K} \longrightarrow u_1 = 206.91 \text{ kJ/kg}$$

$$v_{r1} = 676.1$$

$$v_{r2} = \frac{v_2}{v_1} v_{r1} = \frac{1}{r} v_{r1} = \frac{1}{8} (676.1) = 84.51$$

$$\longrightarrow u_2 = 475.11 \text{ kJ/kg}$$

Process 2-3:  $v = \text{constant}$  heat addition.

$$T_3 = 1800 \text{ K} \longrightarrow u_3 = 1487.2 \text{ kJ/kg}$$

$$v_{r3} = 3.994$$

$$m = \frac{P_1 V_1}{RT_1} = \frac{(98 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(290 \text{ K})} = 7.065 \times 10^{-4} \text{ kg}$$

$$Q_{\text{in}} = m(u_3 - u_2) = (7.065 \times 10^{-4} \text{ kg})(1487.2 - 475.11) \text{ kJ/kg} = \mathbf{0.715 \text{ kJ}}$$

(b) Process 3-4: isentropic expansion.

$$v_{r4} = \frac{v_4}{v_3} v_{r3} = r v_{r3} = (8)(3.994) = 31.95 \longrightarrow u_4 = 693.23 \text{ kJ/kg}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = (7.065 \times 10^{-4} \text{ kg})(693.23 - 206.91) \text{ kJ/kg} = \mathbf{0.344 \text{ kJ}}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 0.715 - 0.344 = 0.371 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{0.371 \text{ kJ}}{0.715 \text{ kJ}} = \mathbf{51.9\%}$$

$$(c) \quad \dot{n} = 2 \frac{\dot{W}_{\text{net}}}{n_{\text{cyl}} W_{\text{net, cyl}}} = (2 \text{ rev/cycle}) \frac{60 \text{ kJ/s}}{4 \times (0.371 \text{ kJ/cycle})} \left( \frac{60 \text{ s}}{1 \text{ min}} \right) = \mathbf{4852 \text{ rpm}}$$

Note that for four-stroke cycles, there are two revolutions per cycle.

**9-166 EES** Problem 9-165 is reconsidered. The effect of the compression ratio net work done and the efficiency of the cycle is to be investigated. Also, the  $T$ - $s$  and  $P$ - $v$  diagrams for the cycle are to be plotted.

**Analysis** Using EES, the problem is solved as follows:

**Air Otto Cycle P-v Diagram****Air Otto Cycle T-s Diagram**

**9-167** An ideal gas Carnot cycle with helium as the working fluid is considered. The pressure ratio, compression ratio, and minimum temperature of the energy source are to be determined.

**Assumptions 1** Kinetic and potential energy changes are negligible. **2** Helium is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of helium is  $k = 1.667$  (Table A-2a).

**Analysis** From the definition of the thermal efficiency of a Carnot heat engine,

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} \longrightarrow T_H = \frac{T_L}{1 - \eta_{\text{th,Carnot}}} = \frac{(15 + 273) \text{ K}}{1 - 0.50} = \mathbf{576 \text{ K}}$$

An isentropic process for an ideal gas is one in which  $Pv^k$  remains constant. Then, the pressure ratio is

$$\frac{P_2}{P_1} = \left( \frac{T_2}{T_1} \right)^{k/(k-1)} = \left( \frac{576 \text{ K}}{288 \text{ K}} \right)^{1.667/(1.667-1)} = \mathbf{5.65}$$

Based on the process equation, the compression ratio is

$$\frac{v_1}{v_2} = \left( \frac{P_2}{P_1} \right)^{1/k} = (5.65)^{1/1.667} = \mathbf{2.83}$$

**9-168E** An ideal gas Carnot cycle with helium as the working fluid is considered. The pressure ratio, compression ratio, and minimum temperature of the energy-source reservoir are to be determined.

**Assumptions 1** Kinetic and potential energy changes are negligible. **2** Helium is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of helium is  $k = 1.667$  (Table A-2Ea).

**Analysis** From the definition of the thermal efficiency of a Carnot heat engine,

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} \longrightarrow T_H = \frac{T_L}{1 - \eta_{\text{th,Carnot}}} = \frac{(60 + 460) \text{ R}}{1 - 0.60} = \mathbf{1300 \text{ R}}$$

An isentropic process for an ideal gas is one in which  $Pv^k$  remains constant. Then, the pressure ratio is

$$\frac{P_2}{P_1} = \left( \frac{T_2}{T_1} \right)^{k/(k-1)} = \left( \frac{1300 \text{ R}}{520 \text{ R}} \right)^{1.667/(1.667-1)} = \mathbf{9.88}$$

Based on the process equation, the compression ratio is

$$\frac{v_1}{v_2} = \left( \frac{P_2}{P_1} \right)^{1/k} = (9.88)^{1/1.667} = \mathbf{3.95}$$

**9-169** The compression ratio required for an ideal Otto cycle to produce certain amount of work when consuming a given amount of fuel is to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats. 4 The combustion efficiency is 100 percent.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** The heat input to the cycle for 0.043 grams of fuel consumption is

$$Q_{\text{in}} = m_{\text{fuel}} q_{\text{HV}} = (0.043 \times 10^{-3} \text{ kg})(42,000 \text{ kJ/kg}) = 1.806 \text{ kJ}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{1 \text{ kJ}}{1.806 \text{ kJ}} = 0.5537$$

From the definition of thermal efficiency, we obtain the required compression ratio to be

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \longrightarrow r = \frac{1}{(1 - \eta_{\text{th}})^{1/(k-1)}} = \frac{1}{(1 - 0.5537)^{1/(1.4-1)}} = \mathbf{7.52}$$

**9-170** An equation is to be developed for  $q_{\text{in}} / (c_v T_1 r^{k-1})$  in terms of  $k$ ,  $r_c$  and  $r_p$ .

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Analysis** The temperatures at various points of the dual cycle are given by

$$T_2 = T_1 r^{k-1}$$

$$T_x = T_2 \left( \frac{P_x}{P_2} \right) = T_2 r_p = r_p T_1 r^{k-1}$$

$$T_3 = T_x \left( \frac{v_3}{v_x} \right) = T_x r_c = r_p r_c T_1 r^{k-1}$$

Application of the first law to the two heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v (T_x - T_2) + c_p (T_3 - T_x) \\ &= c_v (r_p T_1 r^{k-1} - T_1 r^{k-1}) + c_p (r_p r_c T_1 r^{k-1} - r_p T_1 r^{k-1}) \end{aligned}$$

or upon rearrangement

$$\frac{q_{\text{in}}}{c_v T_1 r^{k-1}} = (r_p - 1) + k r_p (r_c - 1)$$

**9-171** An ideal Otto cycle with air as the working fluid with a compression ratio of 9.2 is considered. The amount of heat transferred to the air, the net work output, the thermal efficiency, and the mean effective pressure are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1). The properties of air are given in Table A-17.

**Analysis** (a) Process 1-2: isentropic compression.

$$T_1 = 300 \text{ K} \longrightarrow u_1 = 214.07 \text{ kJ/kg}$$

$$\nu_{r_1} = 621.2$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{9.2} (621.2) = 67.52 \longrightarrow T_2 = 708.3 \text{ K}$$

$$u_2 = 518.9 \text{ kJ/kg}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (9.2) \left( \frac{708.3 \text{ K}}{300 \text{ K}} \right) (98 \text{ kPa}) = 2129 \text{ kPa}$$

Process 2-3:  $\nu = \text{constant}$  heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow T_3 = \frac{P_3}{P_2} T_2 = 2T_2 = (2)(708.3) = 1416.6 \text{ K} \longrightarrow u_3 = 1128.7 \text{ kJ/kg}$$

$$\nu_{r_3} = 8.593$$

$$q_{in} = u_3 - u_2 = 1128.7 - 518.9 = \mathbf{609.8 \text{ kJ/kg}}$$

(b) Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = r \nu_{r_3} = (9.2)(8.593) = 79.06 \longrightarrow u_4 = 487.75 \text{ kJ/kg}$$

Process 4-1:  $\nu = \text{constant}$  heat rejection.

$$q_{out} = u_4 - u_1 = 487.75 - 214.07 = 273.7 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 609.8 - 273.7 = \mathbf{336.1 \text{ kJ/kg}}$$

$$(c) \quad \eta_{th} = \frac{w_{net}}{q_{in}} = \frac{336.1 \text{ kJ/kg}}{609.8 \text{ kJ/kg}} = \mathbf{55.1\%}$$

$$(d) \quad \nu_{max} = \nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})}{98 \text{ kPa}} = 0.879 \text{ m}^3/\text{kg}$$

$$\nu_{min} = \nu_2 = \frac{\nu_{max}}{r}$$

$$\text{MEP} = \frac{w_{net}}{\nu_1 - \nu_2} = \frac{w_{net}}{\nu_1 (1 - 1/r)} = \frac{336.1 \text{ kJ/kg}}{(0.879 \text{ m}^3/\text{kg})(1 - 1/9.2)} \left( \frac{1 \text{ kPa} \cdot \text{m}^3}{1 \text{ kJ}} \right) = \mathbf{429 \text{ kPa}}$$

**9-172** An ideal Otto cycle with air as the working fluid with a compression ratio of 9.2 is considered. The amount of heat transferred to the air, the net work output, the thermal efficiency, and the mean effective pressure are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (a) Process 1-2 is isentropic compression:

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (300 \text{ K})(9.2)^{0.4} = 728.8 \text{ K}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{v_1}{v_2} \frac{T_2}{T_1} P_1 = (9.2) \left( \frac{728.8 \text{ K}}{300 \text{ K}} \right) (98 \text{ kPa}) = 2190 \text{ kPa}$$

Process 2-3:  $v = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow T_3 = \frac{P_3}{P_2} T_2 = 2T_2 = (2)(728.8) = 1457.6 \text{ K}$$

$$q_{in} = u_3 - u_2 = c_v (T_3 - T_2) = (0.718 \text{ kJ/kg}\cdot\text{K})(1457.6 - 728.8) \text{ K} = 523.3 \text{ kJ/kg}$$

(b) Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = (1457.6 \text{ K}) \left( \frac{1}{9.2} \right)^{0.4} = 600.0 \text{ K}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$q_{out} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(600 - 300) \text{ K} = 215.4 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 523.3 - 215.4 = 307.9 \text{ kJ/kg}$$

$$(c) \quad \eta_{th} = \frac{w_{net}}{q_{in}} = \frac{307.9 \text{ kJ/kg}}{523.3 \text{ kJ/kg}} = 58.8\%$$

$$(d) \quad v_{max} = v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})}{98 \text{ kPa}} = 0.879 \text{ m}^3/\text{kg}$$

$$v_{min} = v_2 = \frac{v_{max}}{r}$$

$$MEP = \frac{w_{net}}{v_1 - v_2} = \frac{w_{net}}{v_1 (1 - 1/r)} = \frac{307.9 \text{ kJ/kg}}{(0.879 \text{ m}^3/\text{kg})(1 - 1/9.2)} \left( \frac{1 \text{ kPa}\cdot\text{m}^3}{1 \text{ kJ}} \right) = 393 \text{ kPa}$$

**9-173** An engine operating on the ideal diesel cycle with air as the working fluid is considered. The pressure at the beginning of the heat-rejection process, the net work per cycle, and the mean effective pressure are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1). The properties of air are given in Table A-17.

**Analysis** (a) The compression and the cutoff ratios are

$$r = \frac{V_1}{V_2} = \frac{1200 \text{ cm}^3}{75 \text{ cm}^3} = 16 \quad r_c = \frac{V_3}{V_2} = \frac{150 \text{ cm}^3}{75 \text{ cm}^3} = 2$$

Process 1-2: isentropic compression.

$$T_1 = 290 \text{ K} \longrightarrow u_1 = 206.91 \text{ kJ/kg} \\ v_{r_1} = 676.1$$

$$v_{r_2} = \frac{v_2}{v_1} v_{r_1} = \frac{1}{r} v_{r_1} = \frac{1}{16} (676.1) = 42.256 \longrightarrow T_2 = 837.3 \text{ K} \\ h_2 = 863.03 \text{ kJ/kg}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow T_3 = \frac{v_3}{v_2} T_2 = 2T_2 = (2)(837.3) = 1674.6 \text{ K} \\ \longrightarrow h_3 = 1848.9 \text{ kJ/kg} \\ v_{r_3} = 5.002$$

Process 3-4: isentropic expansion.

$$v_{r_4} = \frac{v_4}{v_3} v_{r_3} = \frac{v_4}{2v_2} v_{r_3} = \frac{r}{2} v_{r_3} = \left(\frac{16}{2}\right)(5.002) = 40.016 \longrightarrow T_4 = 853.4 \text{ K} \\ u_4 = 636.00 \text{ kJ/kg}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$\frac{P_4 v_4}{T_4} = \frac{P_1 v_1}{T_1} \longrightarrow P_4 = \frac{T_4}{T_1} P_1 = \left(\frac{853.4 \text{ K}}{290 \text{ K}}\right)(100 \text{ kPa}) = \mathbf{294.3 \text{ kPa}}$$

$$(b) \quad m = \frac{P_1 V_1}{RT_1} = \frac{(100 \text{ kPa})(0.0012 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(290 \text{ K})} = 1.442 \times 10^{-3} \text{ kg}$$

$$Q_{\text{in}} = m(h_3 - h_2) = (1.442 \times 10^{-3} \text{ kg})(1848.9 - 863.08) = 1.422 \text{ kJ}$$

$$Q_{\text{out}} = m(u_4 - u_1) = (1.442 \times 10^{-3} \text{ kg})(636.00 - 206.91) \text{ kJ/kg} = 0.619 \text{ kJ}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 1.422 - 0.619 = \mathbf{0.803 \text{ kJ}}$$

$$(c) \quad \text{MEP} = \frac{W_{\text{net}}}{V_1 - V_2} = \frac{W_{\text{net}}}{V_1(1 - 1/r)} = \frac{0.803 \text{ kJ}}{(0.0012 \text{ m}^3)(1 - 1/16)} \left(\frac{1 \text{ kPa} \cdot \text{m}^3}{1 \text{ kJ}}\right) = \mathbf{714 \text{ kPa}}$$

**9-174** An engine operating on the ideal diesel cycle with argon as the working fluid is considered. The pressure at the beginning of the heat-rejection process, the net work per cycle, and the mean effective pressure are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Argon is an ideal gas with constant specific heats.

**Properties** The properties of argon at room temperature are  $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.3122 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.667$  (Table A-2).

**Analysis** (a) The compression and the cutoff ratios are

$$r = \frac{V_1}{V_2} = \frac{1200 \text{ cm}^3}{75 \text{ cm}^3} = 16 \quad r_c = \frac{V_3}{V_2} = \frac{150 \text{ cm}^3}{75 \text{ cm}^3} = 2$$

Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{V_2}{V_1} \right)^{k-1} = (290 \text{ K})(16)^{0.667} = 1843 \text{ K}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 V_3}{T_3} = \frac{P_2 V_2}{T_2} \longrightarrow T_3 = \frac{V_3}{V_2} T_2 = 2T_2 = (2)(1843) = 3686 \text{ K}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{V_3}{V_4} \right)^{k-1} = T_3 \left( \frac{2V_2}{V_4} \right)^{k-1} = T_3 \left( \frac{2}{r} \right)^{k-1} = (3686 \text{ K}) \left( \frac{2}{16} \right)^{0.667} = 920.9 \text{ K}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$\frac{P_4 V_4}{T_4} = \frac{P_1 V_1}{T_1} \longrightarrow P_4 = \frac{T_4}{T_1} P_1 = \left( \frac{920.9 \text{ K}}{290 \text{ K}} \right) (100 \text{ kPa}) = \mathbf{317.6 \text{ kPa}}$$

$$(b) \quad m = \frac{P_1 V_1}{RT_1} = \frac{(100 \text{ kPa})(0.0012 \text{ m}^3)}{(0.2081 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(290 \text{ K})} = 1.988 \times 10^{-3} \text{ kg}$$

$$Q_{\text{in}} = m(h_3 - h_2) = mc_p(T_3 - T_2) = (1.988 \times 10^{-3} \text{ kg})(0.5203 \text{ kJ/kg} \cdot \text{K})(3686 - 1843) \text{ K} = 1.906 \text{ kJ}$$

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) = (1.988 \times 10^{-3} \text{ kg})(0.3122 \text{ kJ/kg} \cdot \text{K})(920.9 - 290) \text{ K} = 0.392 \text{ kJ}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 1.906 - 0.392 = \mathbf{1.514 \text{ kJ}}$$

$$(c) \quad \text{MEP} = \frac{W_{\text{net}}}{V_1 - V_2} = \frac{W_{\text{net}}}{V_1(1 - 1/r)} = \frac{1.514 \text{ kJ}}{(0.0012 \text{ m}^3)(1 - 1/16)} \left( \frac{1 \text{ kPa} \cdot \text{m}^3}{1 \text{ kJ}} \right) = \mathbf{1346 \text{ kPa}}$$

**9-175E** An ideal dual cycle with air as the working fluid with a compression ratio of 12 is considered. The thermal efficiency of the cycle is to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 0.240$  Btu/lbm·R,  $c_v = 0.171$  Btu/lbm·R, and  $k = 1.4$  (Table A-2E).

**Analysis** The mass of air is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(14.7 \text{ psia})(75/1728 \text{ ft}^3)}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(550 \text{ R})} = 3.132 \times 10^{-3} \text{ lbm}$$

Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{V_1}{V_2} \right)^{k-1} = (550 \text{ R})(12)^{0.4} = 1486 \text{ R}$$

Process 2-x:  $v = \text{constant}$  heat addition,

$$\begin{aligned} Q_{2-x,\text{in}} &= m(u_x - u_2) = mc_v(T_x - T_2) \\ 0.3 \text{ Btu} &= (3.132 \times 10^{-3} \text{ lbm})(0.171 \text{ Btu/lbm} \cdot \text{R})(T_x - 1486) \text{ R} \longrightarrow T_x = 2046 \text{ R} \end{aligned}$$

Process x-3:  $P = \text{constant}$  heat addition.

$$\begin{aligned} Q_{x-3,\text{in}} &= m(h_3 - h_x) = mc_p(T_3 - T_x) \\ 1.1 \text{ Btu} &= (3.132 \times 10^{-3} \text{ lbm})(0.240 \text{ Btu/lbm} \cdot \text{R})(T_3 - 2046) \text{ R} \longrightarrow T_3 = 3509 \text{ R} \end{aligned}$$

$$\frac{P_3 V_3}{T_3} = \frac{P_x V_x}{T_x} \longrightarrow r_c = \frac{V_3}{V_x} = \frac{T_3}{T_x} = \frac{3509 \text{ R}}{2046 \text{ R}} = 1.715$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{V_3}{V_4} \right)^{k-1} = T_3 \left( \frac{1.715 V_1}{V_4} \right)^{k-1} = T_3 \left( \frac{1.715}{r} \right)^{k-1} = (3509 \text{ R}) \left( \frac{1.715}{12} \right)^{0.4} = 1611 \text{ R}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$\begin{aligned} Q_{\text{out}} &= m(u_4 - u_1) = mc_v(T_4 - T_1) \\ &= (3.132 \times 10^{-3} \text{ lbm})(0.171 \text{ Btu/lbm} \cdot \text{R})(1611 - 550) \text{ R} = 0.568 \text{ Btu} \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}} = 1 - \frac{0.568 \text{ Btu}}{1.4 \text{ Btu}} = \mathbf{59.4\%}$$

**9-176** An ideal Stirling cycle with air as the working fluid is considered. The maximum pressure in the cycle and the net work output are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** (a) The entropy change during process 1-2 is

$$s_2 - s_1 = \frac{q_{12}}{T_H} = \frac{900 \text{ kJ/kg}}{1800 \text{ K}} = 0.5 \text{ kJ/kg}\cdot\text{K}$$

and

$$s_2 - s_1 = c_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} \longrightarrow 0.5 \text{ kJ/kg}\cdot\text{K} = (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{v_2}{v_1} \longrightarrow \frac{v_2}{v_1} = 5.710$$

$$\frac{P_3 v_3}{T_3} = \frac{P_1 v_1}{T_1} \longrightarrow P_1 = P_3 \frac{v_3}{v_1} \frac{T_1}{T_3} = P_3 \frac{v_2}{v_1} \frac{T_1}{T_3} = (200 \text{ kPa})(5.710) \left( \frac{1800 \text{ K}}{350 \text{ K}} \right) = \mathbf{5873 \text{ kPa}}$$

$$(b) \quad w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = \left( 1 - \frac{T_L}{T_H} \right) q_{\text{in}} = \left( 1 - \frac{350 \text{ K}}{1800 \text{ K}} \right) (900 \text{ kJ/kg}) = \mathbf{725 \text{ kJ/kg}}$$

**9-177** A simple ideal Brayton cycle with air as the working fluid is considered. The changes in the net work output per unit mass and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Properties** The properties of air are given in Table A-17.

**Analysis** The properties at various states are

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$T_3 = 1300 \text{ K} \longrightarrow h_3 = 1395.97 \text{ kJ/kg}$$

$$P_{r_3} = 330.9$$

For  $r_p = 6$ ,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (6)(1.386) = 8.316 \longrightarrow h_2 = 501.40 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{6}\right)(330.9) = 55.15 \longrightarrow h_4 = 855.3 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 1395.97 - 501.40 = 894.57 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 855.3 - 300.19 = 555.11 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 894.57 - 555.11 = 339.46 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{339.46 \text{ kJ/kg}}{894.57 \text{ kJ/kg}} = 37.9\%$$

For  $r_p = 12$ ,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (12)(1.386) = 16.63 \longrightarrow h_2 = 610.6 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{12}\right)(330.9) = 27.58 \longrightarrow h_4 = 704.6 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 1395.97 - 610.60 = 785.37 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 704.6 - 300.19 = 404.41 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 785.37 - 404.41 = 380.96 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{380.96 \text{ kJ/kg}}{785.37 \text{ kJ/kg}} = 48.5\%$$

Thus,

(a)  $\Delta w_{\text{net}} = 380.96 - 339.46 = \mathbf{41.5 \text{ kJ/kg}}$  (increase)

(b)  $\Delta \eta_{\text{th}} = 48.5\% - 37.9\% = \mathbf{10.6\%}$  (increase)

**9-178** A simple ideal Brayton cycle with air as the working fluid is considered. The changes in the net work output per unit mass and the thermal efficiency are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** Processes 1-2 and 3-4 are isentropic. Therefore, For  $r_p = 6$ ,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(6)^{0.4/1.4} = 500.6 \text{ K}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left( \frac{1}{6} \right)^{0.4/1.4} = 779.1 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = c_p (T_3 - T_2) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 500.6) \text{ K} = 803.4 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} q_{\text{out}} &= h_4 - h_1 = c_p (T_4 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(779.1 - 300) \text{ K} = 481.5 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 803.4 - 481.5 = 321.9 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{321.9 \text{ kJ/kg}}{803.4 \text{ kJ/kg}} = 40.1\%$$

For  $r_p = 12$ ,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(12)^{0.4/1.4} = 610.2 \text{ K}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left( \frac{1}{12} \right)^{0.4/1.4} = 639.2 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = c_p (T_3 - T_2) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 610.2) \text{ K} = 693.2 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} q_{\text{out}} &= h_4 - h_1 = c_p (T_4 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(639.2 - 300) \text{ K} = 340.9 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 693.2 - 340.9 = 352.3 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{352.3 \text{ kJ/kg}}{693.2 \text{ kJ/kg}} = 50.8\%$$

Thus,

$$(a) \quad \Delta w_{\text{net}} = 352.3 - 321.9 = \mathbf{30.4 \text{ kJ/kg}} \quad (\text{increase})$$

$$(b) \quad \Delta \eta_{\text{th}} = 50.8\% - 40.1\% = \mathbf{10.7\%} \quad (\text{increase})$$

**9-179** A regenerative gas-turbine engine operating with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency are to be determined.

**Assumptions 1** The air-standard assumptions are applicable.

**2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2).

**Analysis** The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine.

$$T_{4s} = T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(3.5)^{0.4/1.4} = 429.1 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_4 = T_2 = T_1 + (T_{2s} - T_1)/\eta_C$$

$$= 300 + (429.1 - 300)/(0.78)$$

$$= 465.5 \text{ K}$$

$$T_{9s} = T_{7s} = T_6 \left( \frac{P_7}{P_6} \right)^{(k-1)/k} = (1200 \text{ K}) \left( \frac{1}{3.5} \right)^{0.4/1.4} = 838.9 \text{ K}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} = \frac{c_p(T_6 - T_7)}{c_p(T_6 - T_{7s})} \longrightarrow T_9 = T_7 = T_6 - \eta_T(T_6 - T_{7s})$$

$$= 1200 - (0.86)(1200 - 838.9)$$

$$= 889.5 \text{ K}$$

$$\varepsilon = \frac{h_5 - h_4}{h_9 - h_4} = \frac{c_p(T_5 - T_4)}{c_p(T_9 - T_4)} \longrightarrow T_5 = T_4 + \varepsilon(T_9 - T_4)$$

$$= 465.5 + (0.72)(889.5 - 465.5)$$

$$= 770.8 \text{ K}$$

$$w_{C,in} = 2(h_2 - h_1) = 2c_p(T_2 - T_1) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(465.5 - 300)\text{K} = 332.7 \text{ kJ/kg}$$

$$w_{T,out} = 2(h_6 - h_7) = 2c_p(T_6 - T_7) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(1200 - 889.5)\text{K} = 624.1 \text{ kJ/kg}$$

Thus,

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{332.7 \text{ kJ/kg}}{624.1 \text{ kJ/kg}} = \mathbf{53.3\%}$$

$$q_{in} = (h_6 - h_5) + (h_8 - h_7) = c_p[(T_6 - T_5) + (T_8 - T_7)]$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})[(1200 - 770.8) + (1200 - 889.5)]\text{K} = 743.4 \text{ kJ/kg}$$

$$w_{net} = w_{T,out} - w_{C,in} = 624.1 - 332.7 = 291.4 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{291.4 \text{ kJ/kg}}{743.4 \text{ kJ/kg}} = \mathbf{39.2\%}$$

**9-180 EES** Problem 9-179 is reconsidered. The effect of the isentropic efficiencies for the compressor and turbine and regenerator effectiveness on net work done and the heat supplied to the cycle is to be investigated. Also, the  $T$ - $s$  diagram for the cycle is to be plotted.

**Analysis** Using EES, the problem is solved as follows:

"Input data"

**9-181** A regenerative gas-turbine engine operating with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Helium is an ideal gas with constant specific heats.

**Properties** The properties of helium at room temperature are  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.667$  (Table A-2).

**Analysis** The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine.

$$T_{4s} = T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(3.5)^{0.667/1.667} = 495.2 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_4 = T_2 = T_1 + (T_{2s} - T_1)/\eta_C$$

$$= 300 + (495.2 - 300)/(0.78)$$

$$= 550.3 \text{ K}$$

$$T_{9s} = T_{7s} = T_6 \left( \frac{P_7}{P_6} \right)^{(k-1)/k} = (1200 \text{ K}) \left( \frac{1}{3.5} \right)^{0.667/1.667} = 726.9 \text{ K}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} = \frac{c_p(T_6 - T_7)}{c_p(T_6 - T_{7s})} \longrightarrow T_9 = T_7 = T_6 - \eta_T(T_6 - T_{7s})$$

$$= 1200 - (0.86)(1200 - 726.9)$$

$$= 793.1 \text{ K}$$

$$\varepsilon = \frac{h_5 - h_4}{h_9 - h_4} = \frac{c_p(T_5 - T_4)}{c_p(T_9 - T_4)} \longrightarrow T_5 = T_4 + \varepsilon(T_9 - T_4)$$

$$= 550.3 + (0.72)(793.1 - 550.3)$$

$$= 725.1 \text{ K}$$

$$w_{C,in} = 2(h_2 - h_1) = 2c_p(T_2 - T_1) = 2(5.1926 \text{ kJ/kg}\cdot\text{K})(550.3 - 300)\text{K} = 2599.4 \text{ kJ/kg}$$

$$w_{T,out} = 2(h_6 - h_7) = 2c_p(T_6 - T_7) = 2(5.1926 \text{ kJ/kg}\cdot\text{K})(1200 - 793.1)\text{K} = 4225.7 \text{ kJ/kg}$$

Thus,

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{2599.4 \text{ kJ/kg}}{4225.7 \text{ kJ/kg}} = \mathbf{61.5\%}$$

$$q_{in} = (h_6 - h_5) + (h_8 - h_7) = c_p[(T_6 - T_5) + (T_8 - T_7)]$$

$$= (5.1926 \text{ kJ/kg}\cdot\text{K})[(1200 - 725.1) + (1200 - 793.1)]\text{K} = 4578.8 \text{ kJ/kg}$$

$$w_{net} = w_{T,out} - w_{C,in} = 4225.7 - 2599.4 = 1626.3 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{1626.3 \text{ kJ/kg}}{4578.8 \text{ kJ/kg}} = \mathbf{35.5\%}$$

**9-182** An ideal gas-turbine cycle with one stage of compression and two stages of expansion and regeneration is considered. The thermal efficiency of the cycle as a function of the compressor pressure ratio and the high-pressure turbine to compressor inlet temperature ratio is to be determined, and to be compared with the efficiency of the standard regenerative cycle.

**Analysis** The  $T$ - $s$  diagram of the cycle is as shown in the figure. If the overall pressure ratio of the cycle is  $r_p$ , which is the pressure ratio across the compressor, then the pressure ratio across each turbine stage in the ideal case becomes  $\sqrt{r_p}$ . Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$T_5 = T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k}$$

$$T_7 = T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left( \frac{1}{\sqrt{r_p}} \right)^{(k-1)/k} = T_3 r_p^{(1-k)/2k}$$

$$T_6 = T_5 \left( \frac{P_6}{P_5} \right)^{(k-1)/k} = T_5 \left( \frac{1}{\sqrt{r_p}} \right)^{(k-1)/k} = T_2 r_p^{(1-k)/2k} = T_1 r_p^{(k-1)/k} r_p^{(1-k)/2k} = T_1 r_p^{(k-1)/2k}$$

Then,

$$q_{in} = h_3 - h_7 = c_p (T_3 - T_7) = c_p T_3 (1 - r_p^{(1-k)/2k})$$

$$q_{out} = h_6 - h_1 = c_p (T_6 - T_1) = c_p T_1 (r_p^{(k-1)/2k} - 1)$$

and thus

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{c_p T_1 (r_p^{(k-1)/2k} - 1)}{c_p T_3 (1 - r_p^{(1-k)/2k})}$$

which simplifies to

$$\eta_{th} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/2k}$$

The thermal efficiency of the single stage ideal regenerative cycle is given as

$$\eta_{th} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/k}$$

Therefore, the regenerative cycle with two stages of expansion has a higher thermal efficiency than the standard regenerative cycle with a single stage of expansion for any given value of the pressure ratio  $r_p$ .

$$\left. \begin{aligned} P_9 &= 100 \text{ kPa} \\ s_9 &= s_8 = 6.9196 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right\} h_{9s} = 996.00 \text{ kJ/kg}$$

$$\eta_T = \frac{h_8 - h_9}{h_8 - h_{9s}} \longrightarrow 0.80 = \frac{1395.6 - h_9}{1395.6 - 996.00} \longrightarrow h_9 = 1075.9 \text{ kJ/kg}$$

Cycle analysis:

$$w_{C,in} = h_2 - h_1 + h_4 - h_3 = 460.88 - 300.43 + 537.83 - 350.78 = 347.50 \text{ kJ/kg}$$

$$w_{T,out} = h_6 - h_7 + h_8 - h_9 = 1514.9 - 1170.1 + 1395.6 - 1075.9 = 664.50 \text{ kJ/kg}$$

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{347.50}{664.50} = \mathbf{0.523}$$

$$w_{net} = w_{T,out} - w_{C,in} = 664.50 - 347.50 = \mathbf{317.0 \text{ kJ/kg}}$$

Regenerator analysis:

$$\varepsilon_{regen} = \frac{h_9 - h_{10}}{h_9 - h_4} \longrightarrow 0.75 = \frac{1075.9 - h_{10}}{1075.9 - 537.83} \longrightarrow h_{10} = 672.36 \text{ kJ/kg}$$

$$\left. \begin{aligned} h_{10} &= 672.36 \text{ K} \\ P_{10} &= 100 \text{ kPa} \end{aligned} \right\} s_{10} = 6.5157 \text{ kJ/kg}\cdot\text{K}$$

$$q_{regen} = h_9 - h_{10} = h_5 - h_4 \longrightarrow 1075.9 - 672.36 = h_5 - 537.83 \longrightarrow h_5 = 941.40 \text{ kJ/kg}$$

$$(b) \quad q_{in} = h_6 - h_5 = 1514.9 - 941.40 = 573.54 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{317.0}{573.54} = \mathbf{0.553}$$

(c) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). The maximum temperature for the cycle can be taken to be the turbine inlet temperature. That is,

$$\eta_{max} = 1 - \frac{T_1}{T_6} = 1 - \frac{300 \text{ K}}{1400 \text{ K}} = 0.786$$

and

$$\eta_{II} = \frac{\eta_{th}}{\eta_{max}} = \frac{0.553}{0.786} = \mathbf{0.704}$$

(d) The exergies at the combustion chamber exit and the regenerator exit are

$$\begin{aligned} x_6 &= h_6 - h_0 - T_0(s_6 - s_0) \\ &= (1514.9 - 300.43) \text{ kJ/kg} - (300 \text{ K})(6.6514 - 5.7054) \text{ kJ/kg}\cdot\text{K} = \mathbf{930.7 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{10} &= h_{10} - h_0 - T_0(s_{10} - s_0) \\ &= (672.36 - 300.43) \text{ kJ/kg} - (300 \text{ K})(6.5157 - 5.7054) \text{ kJ/kg}\cdot\text{K} = \mathbf{128.8 \text{ kJ/kg}} \end{aligned}$$

**9-184** The thermal efficiency of a two-stage gas turbine with regeneration, reheating and intercooling to that of a three-stage gas turbine is to be compared.

**Assumptions 1** The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

### Analysis

#### Two Stages:

The pressure ratio across each stage is

$$r_p = \sqrt{16} = 4$$

The temperatures at the end of compression and expansion are

$$T_c = T_{\min} r_p^{(k-1)/k} = (283 \text{ K})(4)^{0.4/1.4} = 420.5 \text{ K}$$

$$T_e = T_{\max} \left( \frac{1}{r_p} \right)^{(k-1)/k} = (873 \text{ K}) \left( \frac{1}{4} \right)^{0.4/1.4} = 587.5 \text{ K}$$

The heat input and heat output are

$$q_{\text{in}} = 2c_p (T_{\max} - T_e) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(873 - 587.5) \text{ K} = 573.9 \text{ kJ/kg}$$

$$q_{\text{out}} = 2c_p (T_c - T_{\min}) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(420.5 - 283) \text{ K} = 276.4 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{276.4}{573.9} = \mathbf{0.518}$$

#### Three Stages:

The pressure ratio across each stage is

$$r_p = 16^{1/3} = 2.520$$

The temperatures at the end of compression and expansion are

$$T_c = T_{\min} r_p^{(k-1)/k} = (283 \text{ K})(2.520)^{0.4/1.4} = 368.5 \text{ K}$$

$$T_e = T_{\max} \left( \frac{1}{r_p} \right)^{(k-1)/k} = (873 \text{ K}) \left( \frac{1}{2.520} \right)^{0.4/1.4} = 670.4 \text{ K}$$

The heat input and heat output are

$$q_{\text{in}} = 3c_p (T_{\max} - T_e) = 3(1.005 \text{ kJ/kg}\cdot\text{K})(873 - 670.4) \text{ K} = 610.8 \text{ kJ/kg}$$

$$q_{\text{out}} = 3c_p (T_c - T_{\min}) = 3(1.005 \text{ kJ/kg}\cdot\text{K})(368.5 - 283) \text{ K} = 257.8 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{257.8}{610.8} = \mathbf{0.578}$$

**9-185E** A pure jet engine operating on an ideal cycle is considered. The thrust force produced per unit mass flow rate is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

**Properties** The properties of air at room temperature are  $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$  (Table A-1E),  $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working across the two isentropic processes of the cycle yields

$$T_2 = T_1 r_p^{(k-1)/k} = (490 \text{ R})(9)^{0.4/1.4} = 918.0 \text{ R}$$

$$T_5 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (1160 \text{ R}) \left( \frac{1}{9} \right)^{0.4/1.4} = 619.2 \text{ R}$$

The work input to the compressor is

$$w_C = c_p (T_2 - T_1) = (0.24 \text{ Btu/lbm}\cdot\text{R})(918.0 - 490) \text{ R} = 102.7 \text{ Btu/lbm}$$

An energy balance gives the excess enthalpy to be

$$\begin{aligned} \Delta h &= c_p (T_3 - T_5) - w_C \\ &= (0.24 \text{ Btu/lbm}\cdot\text{R})(1160 - 619.2) \text{ R} - 102.7 \text{ Btu/lbm} \\ &= 27.09 \text{ Btu/lbm} \end{aligned}$$

The velocity of the air at the engine exit is determined from

$$\Delta h = \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

Rearranging,

$$\begin{aligned} V_{\text{exit}} &= \left( 2\Delta h + V_{\text{inlet}}^2 \right)^{1/2} \\ &= \left[ 2(27.09 \text{ Btu/lbm}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) + (1200 \text{ ft/s})^2 \right]^{1/2} \\ &= 1672 \text{ ft/s} \end{aligned}$$

The specific impulse is then

$$\frac{F}{\dot{m}} = V_{\text{exit}} - V_{\text{inlet}} = 1672 - 1200 = \mathbf{472 \text{ m/s}}$$

**9-186** A simple ideal Brayton cycle with air as the working fluid operates between the specified temperature limit. The net work is to be determined using constant and variable specific heats.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** (a) Constant specific heats:

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(15)^{0.4/1.4} = 591.8 \text{ K}$$

$$T_4 = T_3 \left( \frac{1}{r_p} \right)^{(k-1)/k} = (873 \text{ K}) \left( \frac{1}{15} \right)^{0.4/1.4} = 402.7 \text{ K}$$

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb}} - w_{\text{comp}} \\ &= c_p (T_3 - T_4) - c_p (T_2 - T_1) \\ &= c_p (T_3 - T_4 + T_1 - T_2) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(873 - 402.7 + 273 - 591.8) \text{ K} \\ &= \mathbf{152.3 \text{ kJ/kg}} \end{aligned}$$

(b) Variable specific heats: (using air properties from Table A-17)

$$T_1 = 273 \text{ K} \longrightarrow \begin{aligned} h_1 &= 273.12 \text{ kJ/kg} \\ P_{r1} &= 0.9980 \end{aligned}$$

$$P_{r2} = \frac{P_2}{P_1} P_{r1} = (15)(0.9980) = 14.97 \longrightarrow h_2 = 592.69 \text{ kJ/kg}$$

$$T_3 = 873 \text{ K} \longrightarrow \begin{aligned} h_3 &= 902.76 \text{ kJ/kg} \\ P_{r3} &= 66.92 \end{aligned}$$

$$P_{r4} = \frac{P_4}{P_3} P_{r3} = \left( \frac{1}{15} \right) (66.92) = 4.461 \longrightarrow h_4 = 419.58 \text{ kJ/kg}$$

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb}} - w_{\text{comp}} \\ &= (h_3 - h_4) - (h_2 - h_1) \\ &= (902.76 - 419.58) - (592.69 - 273.12) \\ &= \mathbf{163.6 \text{ kJ/kg}} \end{aligned}$$

**9-187** An Otto cycle with a compression ratio of 8 is considered. The thermal efficiency is to be determined using constant and variable specific heats.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** (a) Constant specific heats:

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{8^{1.4-1}} = \mathbf{0.5647}$$

(b) Variable specific heats: (using air properties from Table A-17)

Process 1-2: isentropic compression.

$$T_1 = 283 \text{ K} \longrightarrow \begin{matrix} u_1 = 201.9 \text{ kJ/kg} \\ v_{r1} = 718.9 \end{matrix}$$

$$v_{r2} = \frac{v_2}{v_1} v_{r1} = \frac{1}{r} v_{r1} = \frac{1}{8} (718.9) = 89.86 \longrightarrow u_2 = 463.76 \text{ kJ/kg}$$

Process 2-3:  $v = \text{constant}$  heat addition.

$$T_3 = 1173 \text{ K} \longrightarrow \begin{matrix} u_3 = 909.39 \text{ kJ/kg} \\ v_{r3} = 15.529 \end{matrix}$$

$$q_{\text{in}} = u_3 - u_2 = 909.39 - 463.76 = 445.63 \text{ kJ/kg}$$

Process 3-4: isentropic expansion.

$$v_{r4} = \frac{v_4}{v_3} v_{r3} = r v_{r3} = (8)(15.529) = 124.2 \longrightarrow u_4 = 408.06 \text{ kJ/kg}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 408.06 - 201.9 = 206.16 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{206.16 \text{ kJ/kg}}{445.63 \text{ kJ/kg}} = \mathbf{0.5374}$$

**9-188** An ideal diesel engine with air as the working fluid has a compression ratio of 22. The thermal efficiency is to be determined using constant and variable specific heats.

**Assumptions 1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis (a)** Constant specific heats:

Process 1-2: isentropic compression.

$$T_2 = T_1 \left( \frac{v_1}{v_2} \right)^{k-1} = (288 \text{ K})(22)^{0.4} = 991.7 \text{ K}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{1473 \text{ K}}{991.7 \text{ K}} = 1.485$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left( \frac{v_3}{v_4} \right)^{k-1} = T_3 \left( \frac{1.485 v_2}{v_4} \right)^{k-1} = T_3 \left( \frac{1.485}{r} \right)^{k-1} = (1473 \text{ K}) \left( \frac{1.485}{22} \right)^{0.4} = 501.1 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(1473 - 991.7) \text{ K} = 483.7 \text{ kJ/kg}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(501.1 - 288) \text{ K} = 153.0 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 483.7 - 153.0 = 330.7 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{330.7 \text{ kJ/kg}}{483.7 \text{ kJ/kg}} = \mathbf{0.698}$$

(b) Variable specific heats: (using air properties from Table A-17)

Process 1-2: isentropic compression.

$$T_1 = 288 \text{ K} \longrightarrow \begin{aligned} u_1 &= 205.48 \text{ kJ/kg} \\ v_{r1} &= 688.1 \end{aligned}$$

$$v_{r2} = \frac{v_2}{v_1} v_{r1} = \frac{1}{r} v_{r1} = \frac{1}{22} (688.1) = 31.28 \longrightarrow \begin{aligned} T_2 &= 929.2 \text{ K} \\ h_2 &= 965.73 \text{ kJ/kg} \end{aligned}$$

Process 2-3:  $P = \text{constant}$  heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{1473 \text{ K}}{929.2 \text{ K}} = 1.585$$

$$T_3 = 1473 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1603.33 \text{ kJ/kg} \\ v_{r3} &= 7.585 \end{aligned}$$

$$q_{\text{in}} = h_3 - h_2 = 1603.33 - 965.73 = 637.6 \text{ kJ/kg}$$

Process 3-4: isentropic expansion.

$$v_{r4} = \frac{v_4}{v_3} v_{r3} = \frac{v_4}{1.585 v_2} v_{r3} = \frac{r}{1.585} v_{r3} = \frac{22}{1.585} (7.585) = 105.3 \longrightarrow u_4 = 435.61 \text{ kJ/kg}$$

Process 4-1:  $v = \text{constant}$  heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 435.61 - 205.48 = 230.13 \text{ kJ/kg}$$

$$\text{Then } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{230.13 \text{ kJ/kg}}{637.6 \text{ kJ/kg}} = \mathbf{0.639}$$

**9-189** The electricity and the process heat requirements of a manufacturing facility are to be met by a cogeneration plant consisting of a gas-turbine and a heat exchanger for steam production. The mass flow rate of the air in the cycle, the back work ratio, the thermal efficiency, the rate at which steam is produced in the heat exchanger, and the utilization efficiency of the cogeneration plant are to be determined.

**Assumptions** 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) For this problem, we use the properties of air from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Compression

$$T_1 = 30^\circ\text{C} \longrightarrow h_1 = 303.60 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_1 = 30^\circ\text{C} \\ P_1 = 100 \text{ kPa} \end{array} \right\} s_1 = 5.7159 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_2 = s_1 = 5.7159 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 617.37 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.82 = \frac{617.37 - 303.60}{h_2 - 303.60} \longrightarrow h_2 = 686.24 \text{ kJ/kg}$$

Process 3-4: Expansion

$$T_4 = 500^\circ\text{C} \longrightarrow h_4 = 792.62 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.82 = \frac{h_3 - 792.62}{h_3 - h_{4s}}$$

We cannot find the enthalpy at state 3 directly. However, using the following lines in EES together with the isentropic efficiency relation, we find  $h_3 = 1404.7 \text{ kJ/kg}$ ,  $T_3 = 1034^\circ\text{C}$ ,  $s_3 = 6.5699 \text{ kJ/kg} \cdot \text{K}$ . The solution by hand would require a trial-error approach.

$$h_3 = \text{enthalpy}(\text{Air}, T=T_3)$$

$$s_3 = \text{entropy}(\text{Air}, T=T_3, P=P_2)$$

$$h_{4s} = \text{enthalpy}(\text{Air}, P=P_1, s=s_3)$$

Also,

$$T_5 = 350^\circ\text{C} \longrightarrow h_5 = 631.44 \text{ kJ/kg}$$

The inlet water is compressed liquid at  $25^\circ\text{C}$  and at the saturation pressure of steam at  $200^\circ\text{C}$  (1555 kPa). This is not available in the tables but we can obtain it in EES. The alternative is to use saturated liquid enthalpy at the given temperature.

$$\left. \begin{array}{l} T_{w1} = 25^\circ\text{C} \\ P_1 = 1555 \text{ kPa} \end{array} \right\} h_{w1} = 106.27 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_{w2} = 200^\circ\text{C} \\ x_2 = 1 \end{array} \right\} h_{w2} = 2792.0 \text{ kJ/kg}$$

The net work output is

$$w_{C,\text{in}} = h_2 - h_1 = 686.24 - 303.60 = 382.64 \text{ kJ/kg}$$

$$w_{T,\text{out}} = h_3 - h_4 = 1404.7 - 792.62 = 612.03 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 612.03 - 382.64 = 229.39 \text{ kJ/kg}$$

The mass flow rate of air is

$$\dot{m}_a = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{800 \text{ kJ/s}}{229.39 \text{ kJ/kg}} = \mathbf{3.487 \text{ kg/s}}$$

(b) The back work ratio is

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{382.64}{612.03} = \mathbf{0.625}$$

The rate of heat input and the thermal efficiency are

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_3 - h_2) = (3.487 \text{ kg/s})(1404.7 - 686.24) \text{ kJ/kg} = 2505 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{800 \text{ kW}}{2505 \text{ kW}} = \mathbf{0.319}$$

(c) An energy balance on the heat exchanger gives

$$\dot{m}_a (h_4 - h_5) = \dot{m}_w (h_{w2} - h_{w1})$$

$$(3.487 \text{ kg/s})(792.62 - 631.44) \text{ kJ/kg} = \dot{m}_w (2792.0 - 106.27) \text{ kJ/kg} \longrightarrow \dot{m}_w = \mathbf{0.2093 \text{ kg/s}}$$

(d) The heat supplied to the water in the heat exchanger (process heat) and the utilization efficiency are

$$\dot{Q}_p = \dot{m}_w (h_{w2} - h_{w1}) = (0.2093 \text{ kg/s})(2792.0 - 106.27) \text{ kJ/kg} = 562.1 \text{ kW}$$

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_p}{\dot{Q}_{\text{in}}} = \frac{800 + 562.1}{2505 \text{ kW}} = \mathbf{0.544}$$

**9-190** A turbojet aircraft flying is considered. The pressure of the gases at the turbine exit, the mass flow rate of the air through the compressor, the velocity of the gases at the nozzle exit, the propulsive power, and the propulsive efficiency of the cycle are to be determined.

**Assumptions 1** The air-standard assumptions are applicable. **2** Potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-1).

**Analysis (a)** For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

*Diffuser, Process 1-2:*

$$T_1 = -35^\circ\text{C} \longrightarrow h_1 = 238.23 \text{ kJ/kg}$$

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2}$$

$$(238.23 \text{ kJ/kg}) + \frac{(900/3.6 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = h_2 + \frac{(15 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \longrightarrow h_2 = 269.37 \text{ kJ/kg}$$

$$\left. \begin{array}{l} h_2 = 269.37 \text{ kJ/kg} \\ P_2 = 50 \text{ kPa} \end{array} \right\} s_2 = 5.7951 \text{ kJ/kg} \cdot \text{K}$$

*Compressor, Process 2-3:*

$$\left. \begin{array}{l} P_3 = 450 \text{ kPa} \\ s_3 = s_2 = 5.7951 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{3s} = 505.19 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{3s} - h_2}{h_3 - h_2} \longrightarrow 0.83 = \frac{505.19 - 269.37}{h_3 - 269.37} \longrightarrow h_3 = 553.50 \text{ kJ/kg}$$

*Turbine, Process 3-4:*

$$T_4 = 950^\circ\text{C} \longrightarrow h_4 = 1304.8 \text{ kJ/kg}$$

$$h_3 - h_2 = h_4 - h_5 \longrightarrow 553.50 - 269.37 = 1304.8 - h_5 \longrightarrow h_5 = 1020.6 \text{ kJ/kg}$$

where the mass flow rates through the compressor and the turbine are assumed equal.

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow 0.83 = \frac{1304.8 - 1020.6}{1304.8 - h_{5s}} \longrightarrow h_{5s} = 962.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = 950^\circ\text{C} \\ P_4 = 450 \text{ kPa} \end{array} \right\} s_4 = 6.7725 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} h_{5s} = 962.45 \text{ kJ/kg} \\ s_5 = s_4 = 6.7725 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} P_5 = \mathbf{147.4 \text{ kPa}}$$

(b) The mass flow rate of the air through the compressor is

$$\dot{m} = \frac{\dot{W}_C}{h_3 - h_2} = \frac{500 \text{ kJ/s}}{(553.50 - 269.37) \text{ kJ/kg}} = \mathbf{1.760 \text{ kg/s}}$$

(c) Nozzle, Process 5-6:

$$\left. \begin{array}{l} h_5 = 1020.6 \text{ kJ/kg} \\ P_5 = 147.4 \text{ kPa} \end{array} \right\} s_5 = 6.8336 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_6 = 40 \text{ kPa} \\ s_6 = s_5 = 6.8336 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{6s} = 709.66 \text{ kJ/kg}$$

$$\eta_N = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow 0.83 = \frac{1020.6 - h_6}{1020.6 - 709.66} \longrightarrow h_6 = 762.52 \text{ kJ/kg}$$

$$h_5 + \frac{V_5^2}{2} = h_6 + \frac{V_6^2}{2}$$

$$(1020.6 \text{ kJ/kg}) + 0 = 762.52 \text{ kJ/kg} + \frac{V_6^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \longrightarrow V_6 = \mathbf{718.5 \text{ m/s}}$$

where the velocity at nozzle inlet is assumed zero.

(d) The propulsive power and the propulsive efficiency are

$$\dot{W}_p = \dot{m}(V_6 - V_1)V_1 = (1.76 \text{ kg/s})(718.5 \text{ m/s} - 250 \text{ m/s})(250 \text{ m/s}) \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{206.1 \text{ kW}}$$

$$\dot{Q}_{\text{in}} = \dot{m}(h_4 - h_3) = (1.76 \text{ kg/s})(1304.8 - 553.50) \text{ kJ/kg} = 1322 \text{ kW}$$

$$\eta_p = \frac{\dot{W}_p}{\dot{Q}_{\text{in}}} = \frac{206.1 \text{ kW}}{1322 \text{ kW}} = \mathbf{0.156}$$

**9-191 EES** The effects of compression ratio on the net work output and the thermal efficiency of the Otto cycle for given operating conditions is to be investigated.

**9-194 EES** The effects of pressure ratio, maximum cycle temperature, and compressor and turbine inefficiencies on the net work output per unit mass and the thermal efficiency of a simple Brayton cycle with air as the working fluid is to be investigated. Constant specific heats at room temperature are to be used.

**Analysis** Using EES, the problem is solved as follows:

```
Procedure ConstPropResult(T[1],P[1],r_comp,T[3]:Eta_th_ConstProp,Eta_th_easy)
```

```
"For Air:"
```

```
C_V = 0.718 [kJ/kg-K]
```

```
k = 1.4
```

```
T2 = T[1]*r_comp^(k-1)
```

```
P2 = P[1]*r_comp^k
```

```
q_in_23 = C_V*(T[3]-T2)
```

```
T4 = T[3]*(1/r_comp)^(k-1)
```

```
q_out_41 = C_V*(T4-T[1])
```

```
Eta_th_ConstProp = (1-q_out_41/q_in_23)*Convert(, %) "[%]"

| 75                                  | 74.18                                   | 22      |

**9-198 EES** The effect of the number of compression and expansion stages on the thermal efficiency of an ideal regenerative Brayton cycle with multistage compression and expansion and helium as the working fluid is to be investigated.

**Analysis** Using EES, the problem is solved as follows:

"Input data for Helium"

$C_P = 5.1926$  [kJ/kg-K]

$k = 1.667$

"Nstages is the number of compression and expansion stages"

{Nstages = 1}

$T_6 = 1200$  [K]

Pratio = 12

$T_1 = 300$  [K]

$P_1 = 100$  [kPa]

$\text{Eta}_{\text{reg}} = 1.0$  "regenerator effectiveness"

$\text{Eta}_c = 1.0$  "Compressor isentropic efficiency"

$\text{Eta}_t = 1.0$  "Turbine isentropic efficiency"

$R_p = \text{Pratio}^{(1/\text{Nstages})}$

"Isentropic Compressor analysis"

$T_{2s} = T_1 R_p^{((k-1)/k)}$

$P_2 = R_p P_1$

" $T_{2s}$  is the isentropic value of  $T_2$  at compressor exit"

$\text{Eta}_c = w_{\text{compisen}}/w_{\text{comp}}$

"compressor adiabatic efficiency,  $W_{\text{comp}} > W_{\text{compisen}}$ "

"Conservation of energy for the compressor for the isentropic case:

$e_{\text{in}} - e_{\text{out}} = \Delta T_{\text{Ae}} = 0$  for steady-flow"

$w_{\text{compisen}} = C_P (T_{2s} - T_1)$

"Actual compressor analysis:"

$w_{\text{comp}} = C_P (T_2 - T_1)$

"Since intercooling is assumed to occur such that  $T_3 = T_1$  and the compressors have the same pressure ratio, the work input to each compressor is the same. The total compressor work is:"

$w_{\text{comp\_total}} = \text{Nstages} * w_{\text{comp}}$

"External heat exchanger analysis"

"SSSF First Law for the heat exchanger, assuming  $W=0$ ,  $ke=pe=0$

$e_{\text{in}} - e_{\text{out}} = \Delta T_{\text{Ae\_cv}} = 0$  for steady flow"

"The heat added in the external heat exchanger + the reheat between turbines is"

$q_{\text{in\_total}} = C_P (T_6 - T_5) + (\text{Nstages} - 1) * C_P (T_8 - T_7)$

"Reheat is assumed to occur until:"

$T_8 = T_6$

"Turbine analysis"

$P_7 = P_6 / R_p$

" $T_{7s}$  is the isentropic value of  $T_7$  at turbine exit"

$T_{7s} = T_6 (1/R_p)^{((k-1)/k)}$

"Turbine adiabatic efficiency,  $w_{\text{turbisen}} > w_{\text{turb}}$ "

$\text{Eta}_t = w_{\text{turb}}/w_{\text{turbisen}}$

"SSSF First Law for the isentropic turbine, assuming: adiabatic,  $ke=pe=0$

$e_{\text{in}} - e_{\text{out}} = \Delta T_{\text{Ae\_cv}} = 0$  for steady-flow"

$w_{\text{turbisen}} = C_P (T_6 - T_{7s})$

"Actual Turbine analysis:"

$w_{\text{turb}} = C_P (T_6 - T_7)$

$w_{\text{turb\_total}} = \text{Nstages} * w_{\text{turb}}$

"Cycle analysis"

$$w_{\text{net}} = w_{\text{turb\_total}} - w_{\text{comp\_total}}$$

$$\text{Bwr} = w_{\text{comp}} / w_{\text{turb}} \quad \text{"Back work ratio"}$$

$$P_4 = P_2$$

$$P_5 = P_4$$

$$P_6 = P_5$$

$$T_4 = T_2$$

"The regenerator effectiveness gives  $T_5$  as:"

$$\text{Eta}_{\text{reg}} = (T_5 - T_4) / (T_9 - T_4)$$

$$T_9 = T_7$$

"Energy balance on regenerator gives  $T_{10}$  as:"

$$T_4 + T_9 = T_5 + T_{10}$$

"Cycle thermal efficiency with regenerator"

$$\text{Eta}_{\text{th\_regenerative}} = w_{\text{net}} / q_{\text{in\_total}} * \text{Convert}(, \% ) \quad \text{"["\%"]"}$$

"The efficiency of the Ericsson cycle is the same as the Carnot cycle operating between the same max and min temperatures,  $T_6$  and  $T_1$  for this problem."

$$\text{Eta}_{\text{th\_Ericsson}} = (1 - T_1 / T_6) * \text{Convert}(, \% ) \quad \text{"["\%"]"}$$

| $\eta_{\text{th, Ericsson}}$<br>[%] | $\eta_{\text{th, Regenerative}}$<br>[%] | Nstages |
|-------------------------------------|-----------------------------------------|---------|

## Fundamentals of Engineering (FE) Exam Problems

**9-199** An Otto cycle with air as the working fluid has a compression ratio of 8.2. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 24%                      (b) 43%                      (c) 52%                      (d) 57%                      (e) 75%

*Answer* (d) 57%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
r=8.2
k=1.4
Eta_Otto=1-1/r^(k-1)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1/r "Taking efficiency to be 1/r"
W2_Eta = 1/r^(k-1) "Using incorrect relation"
W3_Eta = 1-1/r^(k1-1); k1=1.667 "Using wrong k value"
```

**9-200** For specified limits for the maximum and minimum temperatures, the ideal cycle with the lowest thermal efficiency is

- (a) Carnot                      (b) Stirling                      (c) Ericsson                      (d) Otto                      (e) All are the same

*Answer* (d) Otto

**9-201** A Carnot cycle operates between the temperatures limits of 300 K and 2000 K, and produces 600 kW of net power. The rate of entropy change of the working fluid during the heat addition process is

- (a) 0                      (b) 0.300 kW/K                      (c) 0.353 kW/K                      (d) 0.261 kW/K                      (e) 2.0 kW/K

*Answer* (c) 0.353 kW/K

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
TL=300 "K"
TH=2000 "K"
Wnet=600 "kJ/s"
Wnet= (TH-TL)*DS
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_DS = Wnet/TH "Using TH instead of TH-TL"
W2_DS = Wnet/TL "Using TL instead of TH-TL"
W3_DS = Wnet/(TH+TL) "Using TH+TL instead of TH-TL"
```

**9-202** Air in an ideal Diesel cycle is compressed from 3 L to 0.15 L, and then it expands during the constant pressure heat addition process to 0.30 L. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 35%                      (b) 44%                      (c) 65%                      (d) 70%                      (e) 82%

*Answer* (c) 65%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V1=3 "L"
V2= 0.15 "L"
V3= 0.30 "L"
r=V1/V2
rc=V3/V2
k=1.4
Eta_Diesel=1-(1/r^(k-1))*(rc^k-1)/k/(rc-1)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1-(1/r1^(k-1))*(rc^k-1)/k/(rc-1); r1=V1/V3 "Wrong r value"
W2_Eta = 1-Eta_Diesel "Using incorrect relation"
W3_Eta = 1-(1/r^(k1-1))*(rc^k1-1)/k1/(rc-1); k1=1.667 "Using wrong k value"
W4_Eta = 1-1/r^(k-1) "Using Otto cycle efficiency"
```

**9-203** Helium gas in an ideal Otto cycle is compressed from 20°C and 2.5 L to 0.25 L, and its temperature increases by an additional 700°C during the heat addition process. The temperature of helium before the expansion process is

- (a) 1790°C                      (b) 2060°C                      (c) 1240°C                      (d) 620°C                      (e) 820°C

*Answer* (a) 1790°C

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.667
V1=2.5
V2=0.25
r=V1/V2
T1=20+273 "K"
T2=T1*r^(k-1)
T3=T2+700-273 "C"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T3 = T22+700-273; T22=T1*r^(k1-1); k1=1.4 "Using wrong k value"
W2_T3 = T3+273 "Using K instead of C"
W3_T3 = T1+700-273 "Disregarding temp rise during compression"
W4_T3 = T222+700-273; T222=(T1-273)*r^(k-1) "Using C for T1 instead of K"
```

**9-204** In an ideal Otto cycle, air is compressed from 1.20 kg/m<sup>3</sup> and 2.2 L to 0.26 L, and the net work output of the cycle is 440 kJ/kg. The mean effective pressure (MEP) for this cycle is

- (a) 612 kPa                      (b) 599 kPa                      (c) 528 kPa                      (d) 416 kPa                      (e) 367 kPa

*Answer* (b) 599 kPa

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
rho1=1.20 "kg/m^3"
k=1.4
V1=2.2
V2=0.26
m=rho1*V1/1000 "kg"
w_net=440 "kJ/kg"
Wtotal=m*w_net
MEP=Wtotal/((V1-V2)/1000)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_MEP = w_net/((V1-V2)/1000) "Disregarding mass"
W2_MEP = Wtotal/(V1/1000) "Using V1 instead of V1-V2"
W3_MEP = (rho1*V2/1000)*w_net/((V1-V2)/1000); "Finding mass using V2 instead of V1"
W4_MEP = Wtotal/((V1+V2)/1000) "Adding V1 and V2 instead of subtracting"
```

**9-205** In an ideal Brayton cycle, air is compressed from 95 kPa and 25°C to 800 kPa. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 46%                      (b) 54%                      (c) 57%                      (d) 39%                      (e) 61%

*Answer* (a) 46%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=95 "kPa"
P2=800 "kPa"
T1=25+273 "K"
rp=P2/P1
k=1.4
Eta_Brayton=1-1/rp^((k-1)/k)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1/rp "Taking efficiency to be 1/rp"
W2_Eta = 1/rp^((k-1)/k) "Using incorrect relation"
W3_Eta = 1-1/rp^((k1-1)/k1); k1=1.667 "Using wrong k value"
```

**9-206** Consider an ideal Brayton cycle executed between the pressure limits of 1200 kPa and 100 kPa and temperature limits of 20°C and 1000°C with argon as the working fluid. The net work output of the cycle is

- (a) 68 kJ/kg      (b) 93 kJ/kg      (c) 158 kJ/kg      (d) 186 kJ/kg      (e) 310 kJ/kg

*Answer* (c) 158 kJ/kg

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=100 "kPa"
P2=1200 "kPa"
T1=20+273 "K"
T3=1000+273 "K"
rp=P2/P1
k=1.667
Cp=0.5203 "kJ/kg.K"
Cv=0.3122 "kJ/kg.K"
T2=T1*rp^((k-1)/k)
q_in=Cp*(T3-T2)
Eta_Brayton=1-1/rp^((k-1)/k)
w_net=Eta_Brayton*q_in
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_wnet = (1-1/rp^((k-1)/k))*qin1; qin1=Cv*(T3-T2) "Using Cv instead of Cp"
W2_wnet = (1-1/rp^((k-1)/k))*qin2; qin2=1.005*(T3-T2) "Using Cp of air instead of argon"
W3_wnet = (1-1/rp^((k1-1)/k1))*Cp*(T3-T22); T22=T1*rp^((k1-1)/k1); k1=1.4 "Using k of air instead of argon"
W4_wnet = (1-1/rp^((k-1)/k))*Cp*(T3-T222); T222=(T1-273)*rp^((k-1)/k) "Using C for T1 instead of K"
```

**9-207** An ideal Brayton cycle has a net work output of 150 kJ/kg and a backwork ratio of 0.4. If both the turbine and the compressor had an isentropic efficiency of 85%, the net work output of the cycle would be

- (a) 74 kJ/kg      (b) 95 kJ/kg      (c) 109 kJ/kg      (d) 128 kJ/kg      (e) 177 kJ/kg

*Answer* (b) 95 kJ/kg

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
wcomp/wturb=0.4
wturb-wcomp=150 "kJ/kg"
Eff=0.85
w_net=Eff*wturb-wcomp/Eff
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_wnet = Eff*wturb-wcomp*Eff "Making a mistake in Wnet relation"
W2_wnet = (wturb-wcomp)/Eff "Using a wrong relation"
W3_wnet = wturb/eff-wcomp*Eff "Using a wrong relation"
```

**9-208** In an ideal Brayton cycle, air is compressed from 100 kPa and 25°C to 1 MPa, and then heated to 1200°C before entering the turbine. Under cold air standard conditions, the air temperature at the turbine exit is

- (a) 490°C                      (b) 515°C                      (c) 622°C                      (d) 763°C                      (e) 895°C

*Answer* (a) 490°C

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=100 "kPa"
P2=1000 "kPa"
T1=25+273 "K"
T3=1200+273 "K"
rp=P2/P1
k=1.4
T4=T3*(1/rp)^((k-1)/k)-273
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T4 = T3/rp "Using wrong relation"
W2_T4 = (T3-273)/rp "Using wrong relation"
W3_T4 = T4+273 "Using K instead of C"
W4_T4 = T1+800-273 "Disregarding temp rise during compression"
```

**9-209** In an ideal Brayton cycle with regeneration, argon gas is compressed from 100 kPa and 25°C to 400 kPa, and then heated to 1200°C before entering the turbine. The highest temperature that argon can be heated in the regenerator is

- (a) 246°C                      (b) 846°C                      (c) 689°C                      (d) 368°C                      (e) 573°C

*Answer* (e) 573°C

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.667
Cp=0.5203 "kJ/kg.K"
P1=100 "kPa"
P2=400 "kPa"
T1=25+273 "K"
T3=1200+273 "K"
"The highest temperature that argon can be heated in the regenerator is the turbine exit temperature,"
rp=P2/P1
T2=T1*rp^((k-1)/k)
T4=T3/rp^((k-1)/k)-273
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T4 = T3/rp "Using wrong relation"
W2_T4 = (T3-273)/rp^((k-1)/k) "Using C instead of K for T3"
W3_T4 = T4+273 "Using K instead of C"
W4_T4 = T2-273 "Taking compressor exit temp as the answer"
```

**9-210** In an ideal Brayton cycle with regeneration, air is compressed from 80 kPa and 10°C to 400 kPa and 175°C, is heated to 450°C in the regenerator, and then further heated to 1000°C before entering the turbine. Under cold air standard conditions, the effectiveness of the regenerator is

- (a) 33%                      (b) 44%                      (c) 62%                      (d) 77%                      (e) 89%

Answer (d) 77%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.4
Cp=1.005 "kJ/kg.K"
P1=80 "kPa"
P2=400 "kPa"
T1=10+273 "K"
T2=175+273 "K"
T3=1000+273 "K"
T5=450+273 "K"
"The highest temperature that the gas can be heated in the regenerator is the turbine exit temperature,"
rp=P2/P1
T2check=T1*rp^((k-1)/k) "Checking the given value of T2. It checks."
T4=T3/rp^((k-1)/k)
Effective=(T5-T2)/(T4-T2)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_eff = (T5-T2)/(T3-T2) "Using wrong relation"
W2_eff = (T5-T2)/(T44-T2); T44=(T3-273)/rp^((k-1)/k) "Using C instead of K for T3"
W3_eff = (T5-T2)/(T444-T2); T444=T3/rp "Using wrong relation for T4"
```

**9-211** Consider a gas turbine that has a pressure ratio of 6 and operates on the Brayton cycle with regeneration between the temperature limits of 20°C and 900°C. If the specific heat ratio of the working fluid is 1.3, the highest thermal efficiency this gas turbine can have is

- (a) 38%                      (b) 46%                      (c) 62%                      (d) 58%                      (e) 97%

*Answer* (c) 62%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.3
rp=6
T1=20+273 "K"
T3=900+273 "K"
Eta_regen=1-(T1/T3)*rp^((k-1)/k)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1-((T1-273)/(T3-273))*rp^((k-1)/k) "Using C for temperatures instead of K"
W2_Eta = (T1/T3)*rp^((k-1)/k) "Using incorrect relation"
W3_Eta = 1-(T1/T3)*rp^((k1-1)/k1); k1=1.4 "Using wrong k value (the one for air)"
```

**9-212** An ideal gas turbine cycle with many stages of compression and expansion and a regenerator of 100 percent effectiveness has an overall pressure ratio of 10. Air enters every stage of compressor at 290 K, and every stage of turbine at 1200 K. The thermal efficiency of this gas-turbine cycle is

- (a) 36%                      (b) 40%                      (c) 52%                      (d) 64%                      (e) 76%

*Answer* (e) 76%

W1\_thrust = (Vel2-Vel1)/1000 "Disregarding mass flow rate"

W2\_thrust = m\*Vel2/1000 "Using incorrect relation"

**9-214 ... 9-220 Design and Essay Problems.**

# Chapter 10

## VAPOR AND COMBINED POWER CYCLES

### Carnot Vapor Cycle

**10-1C** Because excessive moisture in steam causes erosion on the turbine blades. The highest moisture content allowed is about 10%.

**10-2C** The Carnot cycle is not a realistic model for steam power plants because (1) limiting the heat transfer processes to two-phase systems to maintain isothermal conditions severely limits the maximum temperature that can be used in the cycle, (2) the turbine will have to handle steam with a high moisture content which causes erosion, and (3) it is not practical to design a compressor that will handle two phases.

**10-3E** A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the quality at the end of the heat rejection process, and the net work output are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) We note that

$$T_H = T_{\text{sat}@180 \text{ psia}} = 373.1^\circ\text{F} = 833.1 \text{ R}$$

$$T_L = T_{\text{sat}@14.7 \text{ psia}} = 212.0^\circ\text{F} = 672.0 \text{ R}$$

and

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{672.0 \text{ R}}{833.1 \text{ R}} = \mathbf{19.3\%}$$

(b) Noting that  $s_4 = s_1 = s_f @ 180 \text{ psia} = 0.53274 \text{ Btu/lbm}\cdot\text{R}$ ,

$$x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{0.53274 - 0.31215}{1.44441} = \mathbf{0.153}$$

(c) The enthalpies before and after the heat addition process are

$$h_1 = h_f @ 180 \text{ psia} = 346.14 \text{ Btu/lbm}$$

$$h_2 = h_f + x_2 h_{fg} = 346.14 + (0.90)(851.16) = 1112.2 \text{ Btu/lbm}$$

Thus,

$$q_{\text{in}} = h_2 - h_1 = 1112.2 - 346.14 = 766.0 \text{ Btu/lbm}$$

and,

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.1934)(766.0 \text{ Btu/lbm}) = \mathbf{148.1 \text{ Btu/lbm}}$$

**10-4** A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the amount of heat rejected, and the net work output are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Noting that  $T_H = 250^\circ\text{C} = 523\text{ K}$  and  $T_L = T_{\text{sat @ } 20\text{ kPa}} = 60.06^\circ\text{C} = 333.1\text{ K}$ , the thermal efficiency becomes

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{333.1\text{ K}}{523\text{ K}} = 0.3632 = \mathbf{36.3\%}$$

(b) The heat supplied during this cycle is simply the enthalpy of vaporization,

$$q_{\text{in}} = h_{fg @ 250^\circ\text{C}} = 1715.3\text{ kJ/kg}$$

Thus,

$$q_{\text{out}} = q_L = \frac{T_L}{T_H} q_{\text{in}} = \left( \frac{333.1\text{ K}}{523\text{ K}} \right) (1715.3\text{ kJ/kg}) = \mathbf{1092.3\text{ kJ/kg}}$$

(c) The net work output of this cycle is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.3632)(1715.3\text{ kJ/kg}) = \mathbf{623.0\text{ kJ/kg}}$$

**10-5** A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the amount of heat rejected, and the net work output are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Noting that  $T_H = 250^\circ\text{C} = 523\text{ K}$  and  $T_L = T_{\text{sat @ } 10\text{ kPa}} = 45.81^\circ\text{C} = 318.8\text{ K}$ , the thermal efficiency becomes

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{318.8\text{ K}}{523\text{ K}} = \mathbf{39.04\%}$$

(b) The heat supplied during this cycle is simply the enthalpy of vaporization,

$$q_{\text{in}} = h_{fg @ 250^\circ\text{C}} = 1715.3\text{ kJ/kg}$$

Thus,

$$q_{\text{out}} = q_L = \frac{T_L}{T_H} q_{\text{in}} = \left( \frac{318.8\text{ K}}{523\text{ K}} \right) (1715.3\text{ kJ/kg}) = \mathbf{1045.6\text{ kJ/kg}}$$

(c) The net work output of this cycle is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.3904)(1715.3\text{ kJ/kg}) = \mathbf{669.7\text{ kJ/kg}}$$

**10-6** A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the pressure at the turbine inlet, and the net work output are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The thermal efficiency is determined from

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{60 + 273 \text{ K}}{350 + 273 \text{ K}} = \mathbf{46.5\%}$$

(b) Note that

$$\begin{aligned} s_2 = s_3 &= s_f + x_3 s_{fg} \\ &= 0.8313 + 0.891 \times 7.0769 = 7.1368 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Thus,

$$\left. \begin{aligned} T_2 &= 350^\circ\text{C} \\ s_2 &= 7.1368 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} P_2 \cong \mathbf{1.40 \text{ MPa}} \text{ (Table A-6)}$$

(c) The net work can be determined by calculating the enclosed area on the  $T$ - $s$  diagram,

$$s_4 = s_f + x_4 s_{fg} = 0.8313 + (0.1)(7.0769) = 1.5390 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$w_{\text{net}} = \text{Area} = (T_H - T_L)(s_3 - s_4) = (350 - 60)(7.1368 - 1.5390) = \mathbf{1623 \text{ kJ/kg}}$$

## The Simple Rankine Cycle

**10-7C** The four processes that make up the simple ideal cycle are (1) Isentropic compression in a pump, (2)  $P = \text{constant}$  heat addition in a boiler, (3) Isentropic expansion in a turbine, and (4)  $P = \text{constant}$  heat rejection in a condenser.

**10-8C** Heat rejected decreases; everything else increases.

**10-9C** Heat rejected decreases; everything else increases.

**10-10C** The pump work remains the same, the moisture content decreases, everything else increases.

**10-11C** The actual vapor power cycles differ from the idealized ones in that the actual cycles involve friction and pressure drops in various components and the piping, and heat loss to the surrounding medium from these components and piping.

**10-12C** The boiler exit pressure will be (a) lower than the boiler inlet pressure in actual cycles, and (b) the same as the boiler inlet pressure in ideal cycles.

**10-13C** We would reject this proposal because  $w_{\text{turb}} = h_1 - h_2 - q_{\text{out}}$ , and any heat loss from the steam will adversely affect the turbine work output.

**10-14C** Yes, because the saturation temperature of steam at 10 kPa is 45.81°C, which is much higher than the temperature of the cooling water.

**10-15E** A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4E, A-5E, and A-6E),

$$\begin{aligned}
 h_1 &= h_f @ 6 \text{ psia} = 138.02 \text{ Btu/lbm} \\
 v_1 &= v_f @ 6 \text{ psia} = 0.01645 \text{ ft}^3/\text{lbm} \\
 w_{p,\text{in}} &= v_1 (P_2 - P_1) \\
 &= (0.01645 \text{ ft}^3/\text{lbm})(500 - 6) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\
 &= 1.50 \text{ Btu/lbm} \\
 h_2 &= h_1 + w_{p,\text{in}} = 138.02 + 1.50 = 139.52 \text{ Btu/lbm} \\
 \left. \begin{aligned} P_3 &= 500 \text{ psia} \\ T_3 &= 1200^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_3 &= 1630.0 \text{ Btu/lbm} \\ s_3 &= 1.8075 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \\
 \left. \begin{aligned} P_4 &= 6 \text{ psia} \\ s_4 &= s_3 \end{aligned} \right\} \begin{aligned} x_4 &= \frac{s_4 - s_f}{s_{fg}} = \frac{1.8075 - 0.24739}{1.58155} = 0.9864 \\ h_4 &= h_f + x_4 h_{fg} = 138.02 + (0.9864)(995.88) = 1120.4 \text{ Btu/lbm} \end{aligned}
 \end{aligned}$$

Knowing the power output from the turbine the mass flow rate of steam in the cycle is determined from

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) \longrightarrow \dot{m} = \frac{\dot{W}_{T,\text{out}}}{h_3 - h_4} = \frac{500 \text{ kJ/s}}{(1630.0 - 1120.4) \text{ Btu/lbm}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 0.9300 \text{ lbm/s}$$

The rates of heat addition and rejection are

$$\begin{aligned}
 \dot{Q}_{\text{in}} &= \dot{m}(h_3 - h_2) = (0.9300 \text{ lbm/s})(1630.0 - 139.52) \text{ Btu/lbm} = \mathbf{1386 \text{ Btu/s}} \\
 \dot{Q}_{\text{out}} &= \dot{m}(h_4 - h_1) = (0.9300 \text{ lbm/s})(1120.4 - 138.02) \text{ Btu/lbm} = \mathbf{913.6 \text{ Btu/s}}
 \end{aligned}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{913.6}{1386} = \mathbf{0.341}$$

**10-16** A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The maximum thermal efficiency of the cycle for a given quality at the turbine exit is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** For maximum thermal efficiency, the quality at state 4 would be at its minimum of 85% (most closely approaches the Carnot cycle), and the properties at state 4 would be (Table A-5)

$$\left. \begin{array}{l} P_4 = 30 \text{ kPa} \\ x_4 = 0.85 \end{array} \right\} \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 289.27 + (0.85)(2335.3) = 2274.3 \text{ kJ/kg} \\ s_4 = s_f + x_4 s_{fg} = 0.9441 + (0.85)(6.8234) = 6.7440 \text{ kJ/kg} \cdot \text{K} \end{array}$$

Since the expansion in the turbine is isentropic,

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ s_3 = s_4 = 6.7440 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_3 = 3115.5 \text{ kJ/kg}$$

Other properties are obtained as follows (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@30 \text{ kPa}} = 289.27 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@30 \text{ kPa}} = 0.001022 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001022 \text{ m}^3/\text{kg})(3000 - 30) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.04 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 289.27 + 3.04 = 292.31 \text{ kJ/kg}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 3115.5 - 292.31 = 2823.2 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2274.3 - 289.27 = 1985.0 \text{ kJ/kg}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1985.0}{2823.2} = \mathbf{0.297}$$

**10-17** A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The power produced by the turbine and consumed by the pump are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@20\text{ kPa}} = 251.42\text{ kJ/kg}$$

$$\nu_1 = \nu_{f@20\text{ kPa}} = 0.001017\text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.001017\text{ m}^3/\text{kg})(4000 - 20)\text{ kPa} \left( \frac{1\text{ kJ}}{1\text{ kPa} \cdot \text{m}^3} \right) \\ &= 4.05\text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 4.05 = 255.47\text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 4000\text{ kPa} \\ T_3 = 700^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3906.3\text{ kJ/kg} \\ s_3 = 7.6214\text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 20\text{ kPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{7.6214 - 0.8320}{7.0752} = 0.9596 \\ h_4 = h_f + x_4 h_{fg} = 251.42 + (0.9596)(2357.5) = 2513.7\text{ kJ/kg} \end{array}$$

The power produced by the turbine and consumed by the pump are

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (50\text{ kg/s})(3906.3 - 2513.7)\text{ kJ/kg} = \mathbf{69,630\text{ kW}}$$

$$\dot{W}_{P,\text{in}} = \dot{m}w_{p,\text{in}} = (50\text{ kg/s})(4.05\text{ kJ/kg}) = \mathbf{203\text{ kW}}$$

**10-18E** A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The turbine inlet temperature and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 5 \text{ psia} = 130.18 \text{ Btu/lbm}$$

$$\nu_1 = \nu_f @ 5 \text{ psia} = 0.01641 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lbm})(2500 - 5) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.58 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 130.18 + 7.58 = 137.76 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_4 = 5 \text{ psia} \\ x_4 = 0.80 \end{array} \right\} \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 130.18 + (0.80)(1000.5) = 930.58 \text{ Btu/lbm} \\ s_4 = s_f + x_4 s_{fg} = 0.23488 + (0.80)(1.60894) = 1.52203 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_3 = 2500 \text{ psia} \\ s_3 = s_4 = 1.52203 \text{ Btu/lbm} \cdot \text{R} \end{array} \right\} \begin{array}{l} h_3 = 1450.8 \text{ Btu/lbm} \\ T_3 = \mathbf{989.2^\circ\text{F}} \end{array}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 1450.8 - 137.76 = 1313.0 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_1 = 930.58 - 130.18 = 800.4 \text{ Btu/lbm}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{800.4}{1313.0} = \mathbf{0.390}$$

**10-19** A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The power produced by the turbine, the heat added in the boiler, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned}
 h_1 &= h_f @ 100 \text{ kPa} = 417.51 \text{ kJ/kg} \\
 \nu_1 &= \nu_f @ 100 \text{ kPa} = 0.001043 \text{ m}^3/\text{kg} \\
 w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\
 &= (0.001043 \text{ m}^3/\text{kg})(15,000 - 100) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\
 &= 15.54 \text{ kJ/kg} \\
 h_2 &= h_1 + w_{p,\text{in}} = 417.51 + 15.54 = 433.05 \text{ kJ/kg} \\
 \left. \begin{aligned} P_3 &= 15,000 \text{ kPa} \\ x_3 &= 1 \end{aligned} \right\} \begin{aligned} h_3 &= 2610.8 \text{ kJ/kg} \\ s_3 &= 5.3108 \text{ kJ/kg} \cdot \text{K} \end{aligned} \\
 \left. \begin{aligned} P_4 &= 100 \text{ kPa} \\ s_4 &= s_3 \end{aligned} \right\} \begin{aligned} x_4 &= \frac{s_4 - s_f}{s_{fg}} = \frac{5.3108 - 1.3028}{6.0562} = 0.6618 \\ h_4 &= h_f + x_4 h_{fg} = 417.51 + (0.6618)(2257.5) = 1911.5 \text{ kJ/kg} \end{aligned}
 \end{aligned}$$

Thus,

$$\begin{aligned}
 w_{T,\text{out}} &= h_3 - h_4 = 2610.8 - 1911.5 = \mathbf{699.3 \text{ kJ/kg}} \\
 q_{\text{in}} &= h_3 - h_2 = 2610.8 - 433.05 = \mathbf{2177.8 \text{ kJ/kg}} \\
 q_{\text{out}} &= h_4 - h_1 = 1911.5 - 417.51 = 1494.0 \text{ kJ/kg}
 \end{aligned}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1494.0}{2177.8} = \mathbf{0.314}$$

**10-20** A simple Rankine cycle with water as the working fluid operates between the specified pressure limits. The isentropic efficiency of the turbine, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@100\text{ kPa}} = 417.51\text{ kJ/kg}$$

$$\nu_1 = \nu_{f@100\text{ kPa}} = 0.001043\text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001043\text{ m}^3/\text{kg})(15,000 - 100)\text{ kPa} \left( \frac{1\text{ kJ}}{1\text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.54\text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 417.51 + 15.54 = 433.05\text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 15,000\text{ kPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2610.8\text{ kJ/kg} \\ s_3 = 5.3108\text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 100\text{ kPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{5.3108 - 1.3028}{6.0562} = 0.6618 \\ h_{4s} = h_f + x_{4s} h_{fg} = 417.51 + (0.6618)(2257.5) = 1911.5\text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_4 = 100\text{ kPa} \\ x_4 = 0.70 \end{array} \right\} h_4 = h_f + x_4 h_{fg} = 417.51 + (0.70)(2257.5) = 1997.8\text{ kJ/kg}$$

The isentropic efficiency of the turbine is

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{2610.8 - 1997.8}{2610.8 - 1911.5} = \mathbf{0.877}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 2610.8 - 433.05 = 2177.8\text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 1997.8 - 417.51 = 1580.3\text{ kJ/kg}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1580.3}{2177.8} = \mathbf{0.274}$$

**10-21E** A simple steam Rankine cycle operates between the specified pressure limits. The mass flow rate, the power produced by the turbine, the rate of heat addition, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 1 \text{ psia} = 69.72 \text{ Btu/lbm}$$

$$\nu_1 = \nu_f @ 6 \text{ psia} = 0.01614 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.01614 \text{ ft}^3/\text{lbm})(2500 - 1) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.46 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 69.72 + 7.46 = 77.18 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 2500 \text{ psia} \\ T_3 = 800^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1302.0 \text{ Btu/lbm} \\ s_3 = 1.4116 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 1 \text{ psia} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{1.4116 - 0.13262}{1.84495} = 0.6932 \\ h_{4s} = h_f + x_{4s} h_{fg} = 69.72 + (0.6932)(1035.7) = 787.70 \text{ Btu/lbm} \end{array}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) = 1302.0 - (0.90)(1302.0 - 787.70) = 839.13 \text{ kJ/kg}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 1302.0 - 77.18 = 1224.8 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_1 = 839.13 - 69.72 = 769.41 \text{ Btu/lbm}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1224.8 - 769.41 = 455.39 \text{ Btu/lbm}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{1000 \text{ kJ/s}}{455.39 \text{ Btu/lbm}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{2.081 \text{ lbm/s}}$$

The power output from the turbine and the rate of heat addition are

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (2.081 \text{ lbm/s})(1302.0 - 839.13) \text{ Btu/lbm} \left( \frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = \mathbf{1016 \text{ kW}}$$

$$\dot{Q}_{\text{in}} = \dot{m} q_{\text{in}} = (2.081 \text{ lbm/s})(1224.8 \text{ Btu/lbm}) = \mathbf{2549 \text{ Btu/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1000 \text{ kJ/s}}{2549 \text{ Btu/s}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{0.3718}$$

**10-22E** A simple steam Rankine cycle operates between the specified pressure limits. The mass flow rate, the power produced by the turbine, the rate of heat addition, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4E, A-5E, and A-6E),

$$\begin{aligned} h_1 &= h_f @ 1 \text{ psia} = 69.72 \text{ Btu/lbm} \\ \nu_1 &= \nu_f @ 6 \text{ psia} = 0.01614 \text{ ft}^3/\text{lbm} \\ w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.01614 \text{ ft}^3/\text{lbm})(2500 - 1) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.46 \text{ Btu/lbm} \\ h_2 &= h_1 + w_{p,\text{in}} = 69.72 + 7.46 = 77.18 \text{ Btu/lbm} \end{aligned}$$

$$\left. \begin{aligned} P_3 &= 2500 \text{ psia} \\ T_3 &= 800^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_3 &= 1302.0 \text{ Btu/lbm} \\ s_3 &= 1.4116 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\left. \begin{aligned} P_4 &= 1 \text{ psia} \\ s_4 &= s_3 \end{aligned} \right\} \begin{aligned} x_{4s} &= \frac{s_4 - s_f}{s_{fg}} = \frac{1.4116 - 0.13262}{1.84495} = 0.6932 \\ h_{4s} &= h_f + x_{4s} h_{fg} = 69.72 + (0.6932)(1035.7) = 787.70 \text{ Btu/lbm} \end{aligned}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) = 1302.0 - (0.90)(1302.0 - 787.70) = 839.13 \text{ kJ/kg}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m}(h_3 - h_4) \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{h_3 - h_4} = \frac{1000 \text{ kJ/s}}{(1302.0 - 839.13) \text{ Btu/lbm}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 2.048 \text{ lbm/s}$$

The rate of heat addition is

$$\dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (2.048 \text{ lbm/s})(1302.0 - 77.18) \text{ Btu/lbm} \left( \frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = 2508 \text{ Btu/s}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1000 \text{ kJ/s}}{2508 \text{ Btu/s}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 0.3779$$

The thermal efficiency in the previous problem was determined to be 0.3718. The error in the thermal efficiency caused by neglecting the pump work is then

$$\text{Error} = \frac{0.3779 - 0.3718}{0.3718} \times 100 = \mathbf{1.64\%}$$

**10-23** A 300-MW coal-fired steam power plant operates on a simple ideal Rankine cycle between the specified pressure limits. The overall plant efficiency and the required rate of the coal supply are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 25 \text{ kPa} = 271.96 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 25 \text{ kPa} = 0.001020 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.00102 \text{ m}^3/\text{kg})(5000 - 25 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.07 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 271.96 + 5.07 = 277.03 \text{ kJ/kg}$$

$$\begin{aligned} P_3 = 5 \text{ MPa} \quad \left. \begin{aligned} h_3 &= 3317.2 \text{ kJ/kg} \\ T_3 &= 450^\circ\text{C} \end{aligned} \right\} \quad \left. \begin{aligned} s_3 &= 6.8210 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_4 = 25 \text{ kPa} \quad \left. \begin{aligned} s_4 &= s_3 \end{aligned} \right\} \quad x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.8210 - 0.8932}{6.9370} = 0.8545 \end{aligned}$$

$$h_4 = h_f + x_4 h_{fg} = 271.96 + (0.8545)(2345.5) = 2276.2 \text{ kJ/kg}$$

The thermal efficiency is determined from

$$q_{\text{in}} = h_3 - h_2 = 3317.2 - 277.03 = 3040.2 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2276.2 - 271.96 = 2004.2 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2004.2}{3040.2} = 0.3407$$

Thus,

$$\eta_{\text{overall}} = \eta_{\text{th}} \times \eta_{\text{comb}} \times \eta_{\text{gen}} = (0.3407)(0.75)(0.96) = \mathbf{24.5\%}$$

(b) Then the required rate of coal supply becomes

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{overall}}} = \frac{300,000 \text{ kJ/s}}{0.2453} = 1,222,992 \text{ kJ/s}$$

and

$$\dot{m}_{\text{coal}} = \frac{\dot{Q}_{\text{in}}}{C_{\text{coal}}} = \frac{1,222,992 \text{ kJ/s}}{29,300 \text{ kJ/kg}} \left( \frac{1 \text{ ton}}{1000 \text{ kg}} \right) = 0.04174 \text{ tons/s} = \mathbf{150.3 \text{ tons/h}}$$

**10-24** A solar-pond power plant that operates on a simple ideal Rankine cycle with refrigerant-134a as the working fluid is considered. The thermal efficiency of the cycle and the power output of the plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\begin{aligned} h_1 &= h_f @ 0.7 \text{ MPa} = 88.82 \text{ kJ/kg} \\ \nu_1 &= \nu_f @ 0.7 \text{ MPa} = 0.0008331 \text{ m}^3/\text{kg} \\ w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.0008331 \text{ m}^3/\text{kg})(1400 - 700 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.58 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 88.82 + 0.58 = 89.40 \text{ kJ/kg}$$

$$\begin{aligned} P_3 &= 1.4 \text{ MPa} \left\{ \begin{aligned} h_3 &= h_{g@1.4 \text{ MPa}} = 276.12 \text{ kJ/kg} \\ s_3 &= s_{g@1.4 \text{ MPa}} = 0.9105 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_4 &= 0.7 \text{ MPa} \left\{ \begin{aligned} x_4 &= \frac{s_4 - s_f}{s_{fg}} = \frac{0.9105 - 0.33230}{0.58763} = 0.9839 \end{aligned} \right. \\ s_4 &= s_3 \end{aligned}$$

$$h_4 = h_f + x_4 h_{fg} = 88.82 + (0.9839)(176.21) = 262.20 \text{ kJ/kg}$$

Thus ,

$$q_{\text{in}} = h_3 - h_2 = 276.12 - 89.40 = 186.72 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 262.20 - 88.82 = 173.38 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 186.72 - 173.38 = 13.34 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{13.34 \text{ kJ/kg}}{186.72 \text{ kJ/kg}} = 7.1\%$$

$$(b) \quad \dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (3 \text{ kg/s})(13.34 \text{ kJ/kg}) = 40.02 \text{ kW}$$

**10-25** A steam power plant operates on a simple ideal Rankine cycle between the specified pressure limits. The thermal efficiency of the cycle, the mass flow rate of the steam, and the temperature rise of the cooling water are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned} h_1 &= h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg} \\ \nu_1 &= \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg} \\ w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(7,000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 7.06 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 7.06 = 198.87 \text{ kJ/kg}$$

$$\begin{aligned} P_3 &= 7 \text{ MPa} \quad \left. \begin{aligned} h_3 &= 3411.4 \text{ kJ/kg} \\ T_3 &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} s_3 &= 6.8000 \text{ kJ/kg} \cdot \text{K} \end{aligned} \end{aligned}$$

$$\begin{aligned} P_4 &= 10 \text{ kPa} \quad \left. \begin{aligned} s_4 &= s_3 \end{aligned} \right\} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.8000 - 0.6492}{7.4996} = 0.8201 \end{aligned}$$

$$h_4 = h_f + x_4 h_{fg} = 191.81 + (0.8201)(2392.1) = 2153.6 \text{ kJ/kg}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 3411.4 - 198.87 = 3212.5 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2153.6 - 191.81 = 1961.8 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3212.5 - 1961.8 = 1250.7 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1250.7 \text{ kJ/kg}}{3212.5 \text{ kJ/kg}} = \mathbf{38.9\%}$$

$$(b) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{45,000 \text{ kJ/s}}{1250.7 \text{ kJ/kg}} = \mathbf{36.0 \text{ kg/s}}$$

(c) The rate of heat rejection to the cooling water and its temperature rise are

$$\begin{aligned} \dot{Q}_{\text{out}} &= \dot{m} q_{\text{out}} = (36.0 \text{ kg/s})(1961.8 \text{ kJ/kg}) = 70,586 \text{ kJ/s} \\ \Delta T_{\text{cooling water}} &= \frac{\dot{Q}_{\text{out}}}{(\dot{m}c)_{\text{cooling water}}} = \frac{70,586 \text{ kJ/s}}{(2000 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})} = \mathbf{8.4^\circ\text{C}} \end{aligned}$$

**10-26** A steam power plant operates on a simple nonideal Rankine cycle between the specified pressure limits. The thermal efficiency of the cycle, the mass flow rate of the steam, and the temperature rise of the cooling water are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.00101 \text{ m}^3/\text{kg}) (7,000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.87) \\ &= 8.11 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 8.11 = 199.92 \text{ kJ/kg}$$

$$\begin{aligned} P_3 = 7 \text{ MPa} \quad & \left. \begin{aligned} h_3 &= 3411.4 \text{ kJ/kg} \\ T_3 &= 500^\circ\text{C} \end{aligned} \right\} s_3 = 6.8000 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} P_4 = 10 \text{ kPa} \quad & \left. \begin{aligned} s_4 &= s_3 \end{aligned} \right\} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.8000 - 0.6492}{7.4996} = 0.8201 \end{aligned}$$

$$h_{4s} = h_f + x_4 h_{fg} = 191.81 + (0.8201)(2392.1) = 2153.6 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 &= h_3 - \eta_T (h_3 - h_{4s}) \\ &= 3411.4 - (0.87)(3411.4 - 2153.6) = 2317.1 \text{ kJ/kg} \end{aligned}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 3411.4 - 199.92 = 3211.5 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2317.1 - 191.81 = 2125.3 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3211.5 - 2125.3 = 1086.2 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1086.2 \text{ kJ/kg}}{3211.5 \text{ kJ/kg}} = \mathbf{33.8\%}$$

$$(b) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{45,000 \text{ kJ/s}}{1086.2 \text{ kJ/kg}} = \mathbf{41.43 \text{ kg/s}}$$

(c) The rate of heat rejection to the cooling water and its temperature rise are

$$\dot{Q}_{\text{out}} = \dot{m} q_{\text{out}} = (41.43 \text{ kg/s})(2125.3 \text{ kJ/kg}) = 88,051 \text{ kJ/s}$$

$$\Delta T_{\text{cooling water}} = \frac{\dot{Q}_{\text{out}}}{(\dot{m}c)_{\text{cooling water}}} = \frac{88,051 \text{ kJ/s}}{(2000 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})} = \mathbf{10.5^\circ\text{C}}$$

**10-27** The net work outputs and the thermal efficiencies for a Carnot cycle and a simple ideal Rankine cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Rankine cycle analysis: From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(10,000 - 20) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.15 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 10.15 = 261.57 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 10 \text{ MPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2725.5 \text{ kJ/kg} \\ s_3 = 5.6159 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 20 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{5.6159 - 0.8320}{7.0752} = 0.6761 \end{array}$$

$$\begin{aligned} h_4 &= h_f + x_4 h_{fg} = 251.42 + (0.6761)(2357.5) \\ &= 1845.3 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{in}} = h_3 - h_2 = 2725.5 - 261.57 = 2463.9 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 1845.3 - 251.42 = 1594.0 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2463.9 - 1594.0 = \mathbf{869.9 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1594.0}{2463.9} = \mathbf{0.353}$$

(b) Carnot Cycle analysis:

$$\left. \begin{array}{l} P_3 = 10 \text{ MPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2725.5 \text{ kJ/kg} \\ T_3 = 311.0^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} T_2 = T_3 = 311.0^\circ\text{C} \\ x_2 = 0 \end{array} \right\} \begin{array}{l} h_2 = 1407.8 \text{ kJ/kg} \\ s_2 = 3.3603 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_1 = 20 \text{ kPa} \\ s_1 = s_2 \end{array} \right\} \begin{array}{l} x_1 = \frac{s_1 - s_f}{s_{fg}} = \frac{3.3603 - 0.8320}{7.0752} = 0.3574 \\ h_1 = h_f + x_1 h_{fg} \\ = 251.42 + (0.3574)(2357.5) = 1093.9 \text{ kJ/kg} \end{array}$$

$$q_{\text{in}} = h_3 - h_2 = 2725.5 - 1407.8 = 1317.7 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 1845.3 - 1093.9 = 751.4 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1317.7 - 752.3 = \mathbf{565.4 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{751.4}{1317.7} = \mathbf{0.430}$$

**10-28** A single-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The mass flow rate of steam through the turbine, the isentropic efficiency of the turbine, the power output from the turbine, and the thermal efficiency of the plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = \frac{h_2 - h_f}{h_{fg}} = \frac{990.14 - 640.09}{2108} = 0.1661$$

The mass flow rate of steam through the turbine is

$$\begin{aligned} \dot{m}_3 &= x_2 \dot{m}_1 \\ &= (0.1661)(230 \text{ kg/s}) \\ &= \mathbf{38.20 \text{ kg/s}} \end{aligned}$$

(b) Turbine:

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2748.1 \text{ kJ/kg} \\ s_3 = 6.8207 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 2160.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = h_f + x_4 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{2748.1 - 2344.7}{2748.1 - 2160.3} = \mathbf{0.686}$$

(c) The power output from the turbine is

$$\dot{W}_{T,\text{out}} = \dot{m}_3 (h_3 - h_4) = (38.20 \text{ kJ/kg})(2748.1 - 2344.7) \text{ kJ/kg} = \mathbf{15,410 \text{ kW}}$$

(d) We use saturated liquid state at the standard temperature for dead state enthalpy

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{15,410}{203,622} = 0.0757 = \mathbf{7.6\%}$$

**10-29** A double-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The temperature of the steam at the exit of the second flash chamber, the power produced from the second turbine, and the thermal efficiency of the plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = 0.1661$$

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = 38.20 \text{ kg/s}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 0.1661 = 191.80 \text{ kg/s}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} h_3 = 2748.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = 2344.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = 640.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_7 = 150 \text{ kPa} \\ h_7 = h_6 \end{array} \right\} \begin{array}{l} T_7 = \mathbf{111.35^\circ\text{C}} \\ x_7 = 0.0777 \end{array}$$

$$\left. \begin{array}{l} P_8 = 150 \text{ kPa} \\ x_8 = 1 \end{array} \right\} h_8 = 2693.1 \text{ kJ/kg}$$

(b) The mass flow rate at the lower stage of the turbine is

$$\dot{m}_8 = x_7 \dot{m}_6 = (0.0777)(191.80 \text{ kg/s}) = 14.90 \text{ kg/s}$$

The power outputs from the high and low pressure stages of the turbine are

$$\dot{W}_{T1,\text{out}} = \dot{m}_3(h_3 - h_4) = (38.20 \text{ kJ/kg})(2748.1 - 2344.7) \text{ kJ/kg} = 15,410 \text{ kW}$$

$$\dot{W}_{T2,\text{out}} = \dot{m}_8(h_8 - h_4) = (14.90 \text{ kJ/kg})(2693.1 - 2344.7) \text{ kJ/kg} = \mathbf{5191 \text{ kW}}$$

(c) We use saturated liquid state at the standard temperature for the dead state enthalpy

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} = \dot{m}_1(h_1 - h_0) = (230 \text{ kg/s})(990.14 - 104.83) \text{ kJ/kg} = 203,621 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{15,410 + 5193}{203,621} = 0.101 = \mathbf{10.1\%}$$

**10-30** A combined flash-binary geothermal power plant uses hot geothermal water at 230°C as the heat source. The mass flow rate of isobutane in the binary cycle, the net power outputs from the steam turbine and the binary cycle, and the thermal efficiencies for the binary cycle and the combined plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = 0.1661$$

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = 38.20 \text{ kg/s}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 38.20 = 191.80 \text{ kg/s}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} h_3 = 2748.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = 2344.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = 640.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = 90^\circ\text{C} \\ x_7 = 0 \end{array} \right\} h_7 = 377.04 \text{ kJ/kg}$$

The isobutane properties are obtained from EES:

$$\left. \begin{array}{l} P_8 = 3250 \text{ kPa} \\ T_8 = 145^\circ\text{C} \end{array} \right\} h_8 = 755.05 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 400 \text{ kPa} \\ T_9 = 80^\circ\text{C} \end{array} \right\} h_9 = 691.01 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{10} = 400 \text{ kPa} \\ x_{10} = 0 \end{array} \right\} \begin{array}{l} h_{10} = 270.83 \text{ kJ/kg} \\ v_{10} = 0.001839 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned} w_{p,\text{in}} &= v_{10}(P_{11} - P_{10})/\eta_p \\ &= (0.001819 \text{ m}^3/\text{kg})(3250 - 400) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.90 \\ &= 5.82 \text{ kJ/kg} \end{aligned}$$

$$h_{11} = h_{10} + w_{p,\text{in}} = 270.83 + 5.82 = 276.65 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives

$$\dot{m}_6(h_6 - h_7) = \dot{m}_{\text{iso}}(h_8 - h_{11})$$

$$(191.81 \text{ kg/s})(640.09 - 377.04) \text{ kJ/kg} = \dot{m}_{\text{iso}}(755.05 - 276.65) \text{ kJ/kg} \longrightarrow \dot{m}_{\text{iso}} = \mathbf{105.46 \text{ kg/s}}$$

(b) The power outputs from the steam turbine and the binary cycle are

$$\dot{W}_{\text{T,steam}} = \dot{m}_3(h_3 - h_4) = (38.19 \text{ kg/s})(2748.1 - 2344.7) \text{ kJ/kg} = \mathbf{15,410 \text{ kW}}$$

$$\dot{W}_{T,iso} = \dot{m}_{iso} (h_8 - h_9) = (105.46 \text{ kJ/kg})(755.05 - 691.01) \text{ kJ/kg} = 6753 \text{ kW}$$

$$\dot{W}_{net,binary} = \dot{W}_{T,iso} - \dot{m}_{iso} w_{p,in} = 6753 - (105.46 \text{ kg/s})(5.82 \text{ kJ/kg}) = \mathbf{6139 \text{ kW}}$$

(c) The thermal efficiencies of the binary cycle and the combined plant are

$$\dot{Q}_{in,binary} = \dot{m}_{iso} (h_8 - h_{11}) = (105.46 \text{ kJ/kg})(755.05 - 276.65) \text{ kJ/kg} = 50,454 \text{ kW}$$

$$\eta_{th,binary} = \frac{\dot{W}_{net,binary}}{\dot{Q}_{in,binary}} = \frac{6139}{50,454} = 0.122 = \mathbf{12.2\%}$$

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{in} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{th,plant} = \frac{\dot{W}_{T,steam} + \dot{W}_{net,binary}}{\dot{E}_{in}} = \frac{15,410 + 6139}{203,622} = 0.106 = \mathbf{10.6\%}$$

## The Reheat Rankine Cycle

**10-31C** The pump work remains the same, the moisture content decreases, everything else increases.

**10-32C** The  $T$ - $s$  diagram shows two reheat cases for the reheat Rankine cycle similar to the one shown in Figure 10-11. In the first case there is expansion through the high-pressure turbine from 6000 kPa to 4000 kPa between states 1 and 2 with reheat at 4000 kPa to state 3 and finally expansion in the low-pressure turbine to state 4. In the second case there is expansion through the high-pressure turbine from 6000 kPa to 500 kPa between states 1 and 5 with reheat at 500 kPa to state 6 and finally expansion in the low-pressure turbine to state 7. Increasing the pressure for reheating increases the average temperature for heat addition makes the energy of the steam more available for doing work, see the reheat process 2 to 3 versus the reheat process 5 to 6. Increasing the reheat pressure will increase the cycle efficiency. However, as the reheating pressure increases, the amount of condensation increases during the expansion process in the low-pressure turbine, state 4 versus state 7. An optimal pressure for reheating generally allows for the moisture content of the steam at the low-pressure turbine exit to be in the range of 10 to 15% and this corresponds to quality in the range of 85 to 90%.

**10-33C** The thermal efficiency of the simple ideal Rankine cycle will probably be higher since the average temperature at which heat is added will be higher in this case.

**10-34 [Also solved by EES on enclosed CD]** A steam power plant that operates on the ideal reheat Rankine cycle is considered. The turbine work output and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(8000 - 20 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 8.12 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 8.12 = 259.54 \text{ kJ/kg}$$

$$\begin{aligned} P_3 = 8 \text{ MPa} \quad \left. \begin{aligned} h_3 &= 3399.5 \text{ kJ/kg} \\ T_3 &= 500^\circ\text{C} \end{aligned} \right\} \quad \left. \begin{aligned} s_3 &= 6.7266 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_4 = 3 \text{ MPa} \quad \left. \begin{aligned} h_4 &= 3105.1 \text{ kJ/kg} \\ s_4 &= s_3 \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_5 = 3 \text{ MPa} \quad \left. \begin{aligned} h_5 &= 3457.2 \text{ kJ/kg} \\ T_5 &= 500^\circ\text{C} \end{aligned} \right\} \quad \left. \begin{aligned} s_5 &= 7.2359 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_6 = 20 \text{ kPa} \quad \left. \begin{aligned} x_6 &= \frac{s_6 - s_f}{s_{fg}} = \frac{7.2359 - 0.8320}{7.0752} = 0.9051 \\ s_6 &= s_5 \end{aligned} \right\} \quad \left. \begin{aligned} h_6 &= h_f + x_6 h_{fg} = 251.42 + (0.9051)(2357.5) = 2385.2 \text{ kJ/kg} \end{aligned} \right\} \end{aligned}$$

The turbine work output and the thermal efficiency are determined from

$$w_{T,\text{out}} = (h_3 - h_4) + (h_5 - h_6) = 3399.5 - 3105.1 + 3457.2 - 2385.2 = \mathbf{1366.4 \text{ kJ/kg}}$$

and

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3399.5 - 259.54 + 3457.2 - 3105.1 = 3492.0 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 1366.4 - 8.12 = 1358.3 \text{ kJ/kg}$$

Thus,

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1358.3 \text{ kJ/kg}}{3492.5 \text{ kJ/kg}} = \mathbf{38.9\%}$$

**10-35 EES** Problem 10-34 is reconsidered. The problem is to be solved by the diagram window data entry feature of EES by including the effects of the turbine and pump efficiencies and reheat on the steam quality at the low-pressure turbine exit. Also, the  $T$ - $s$  diagram is to be plotted.

**Analysis** The problem is solved using EES, and the solution is given below.

**10-36E** An ideal reheat steam Rankine cycle produces 5000 kW power. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4E, A-5E, and A-6E or EES),

$$\begin{aligned}
 h_1 &= h_f @ 10 \text{ psia} = 161.25 \text{ Btu/lbm} \\
 v_1 &= v_f @ 10 \text{ psia} = 0.01659 \text{ ft}^3/\text{lbm} \\
 w_{p,\text{in}} &= v_1(P_2 - P_1) \\
 &= (0.01659 \text{ ft}^3/\text{lbm})(600 - 10) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\
 &= 1.81 \text{ Btu/lbm} \\
 h_2 &= h_1 + w_{p,\text{in}} = 161.25 + 1.81 = 163.06 \text{ Btu/lbm}
 \end{aligned}$$

$$\left. \begin{aligned} P_3 &= 600 \text{ psia} \\ T_3 &= 600^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_3 &= 1289.9 \text{ Btu/lbm} \\ s_3 &= 1.5325 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\left. \begin{aligned} P_4 &= 200 \text{ psia} \\ s_4 &= s_3 \end{aligned} \right\} \begin{aligned} x_4 &= \frac{s_4 - s_f}{s_{fg}} = \frac{1.5325 - 0.54379}{1.00219} = 0.9865 \\ h_4 &= h_f + x_4 h_{fg} = 355.46 + (0.9865)(843.33) = 1187.5 \text{ Btu/lbm} \end{aligned}$$

$$\left. \begin{aligned} P_5 &= 200 \text{ psia} \\ T_5 &= 600^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_5 &= 1322.3 \text{ Btu/lbm} \\ s_5 &= 1.6771 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\left. \begin{aligned} P_6 &= 10 \text{ psia} \\ s_6 &= s_5 \end{aligned} \right\} \begin{aligned} x_6 &= \frac{s_6 - s_f}{s_{fg}} = \frac{1.6771 - 0.28362}{1.50391} = 0.9266 \\ h_6 &= h_f + x_6 h_{fg} = 161.25 + (0.9266)(981.82) = 1071.0 \text{ Btu/lbm} \end{aligned}$$

Thus,

$$\begin{aligned}
 q_{\text{in}} &= (h_3 - h_2) + (h_5 - h_4) = 1289.9 - 163.06 + 1322.3 - 1187.5 = 1261.7 \text{ Btu/lbm} \\
 q_{\text{out}} &= h_6 - h_1 = 1071.0 - 161.25 = 909.7 \text{ Btu/lbm} \\
 w_{\text{net}} &= q_{\text{in}} - q_{\text{out}} = 1261.7 - 909.8 = 352.0 \text{ Btu/lbm}
 \end{aligned}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{5000 \text{ kJ/s}}{352.0 \text{ Btu/lbm}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 13.47 \text{ lbm/s}$$

The rates of heat addition and rejection are

$$\begin{aligned}
 \dot{Q}_{\text{in}} &= \dot{m} q_{\text{in}} = (13.47 \text{ lbm/s})(1261.7 \text{ Btu/lbm}) = \mathbf{16,995 \text{ Btu/s}} \\
 \dot{Q}_{\text{out}} &= \dot{m} q_{\text{out}} = (13.47 \text{ lbm/s})(909.7 \text{ Btu/lbm}) = \mathbf{12,250 \text{ Btu/s}}
 \end{aligned}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{5000 \text{ kJ/s}}{16,990 \text{ Btu/s}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{0.2790}$$

**10-37E** An ideal reheat steam Rankine cycle produces 5000 kW power. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined for a reheat pressure of 100 psia.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4E, A-5E, and A-6E or EES),

$$\begin{aligned} h_1 &= h_f @ 10 \text{ psia} = 161.25 \text{ Btu/lbm} \\ \nu_1 &= \nu_f @ 6 \text{ psia} = 0.01659 \text{ ft}^3/\text{lbm} \\ w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.01659 \text{ ft}^3/\text{lbm})(600 - 10) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 1.81 \text{ Btu/lbm} \\ h_2 &= h_1 + w_{p,\text{in}} = 161.25 + 1.81 = 163.06 \text{ Btu/lbm} \end{aligned}$$

$$\left. \begin{array}{l} P_3 = 600 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1289.9 \text{ Btu/lbm} \\ s_3 = 1.5325 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 100 \text{ psia} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5325 - 0.47427}{1.12888} = 0.9374 \\ h_4 = h_f + x_4 h_{fg} = 298.51 + (0.9374)(888.99) = 1131.9 \text{ Btu/lbm} \end{array}$$

$$\left. \begin{array}{l} P_5 = 100 \text{ psia} \\ T_5 = 600^\circ\text{F} \end{array} \right\} \begin{array}{l} h_5 = 1329.4 \text{ Btu/lbm} \\ s_5 = 1.7586 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ psia} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{1.7586 - 0.28362}{1.50391} = 0.9808 \\ h_6 = h_f + x_6 h_{fg} = 161.25 + (0.9808)(981.82) = 1124.2 \text{ Btu/lbm} \end{array}$$

Thus,

$$\begin{aligned} q_{\text{in}} &= (h_3 - h_2) + (h_5 - h_4) = 1289.9 - 163.07 + 1329.4 - 1131.9 = 1324.4 \text{ Btu/lbm} \\ q_{\text{out}} &= h_6 - h_1 = 1124.2 - 161.25 = 962.9 \text{ Btu/lbm} \\ w_{\text{net}} &= q_{\text{in}} - q_{\text{out}} = 1324.4 - 962.9 = 361.5 \text{ Btu/lbm} \end{aligned}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{5000 \text{ kJ/s}}{361.5 \text{ Btu/lbm}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 13.11 \text{ lbm/s}$$

The rates of heat addition and rejection are

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m} q_{\text{in}} = (13.11 \text{ lbm/s})(1324.4 \text{ Btu/lbm}) = \mathbf{17,360 \text{ Btu/s}} \\ \dot{Q}_{\text{out}} &= \dot{m} q_{\text{out}} = (13.11 \text{ lbm/s})(962.9 \text{ Btu/lbm}) = \mathbf{12,620 \text{ Btu/s}} \end{aligned}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{5000 \text{ kJ/s}}{17,360 \text{ Btu/s}} \left( \frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{0.2729}$$

**Discussion** The thermal efficiency for 200 psia reheat pressure was determined in the previous problem to be 0.2790. Thus, operating the reheater at 100 psia causes a slight decrease in the thermal efficiency.

**10-38** An ideal reheat Rankine with water as the working fluid is considered. The temperatures at the inlet of both turbines, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10 \text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@10 \text{ kPa}} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001010 \text{ m}^3/\text{kg})(4000 - 10) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 4.03 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 4.03 = 195.84 \text{ kJ/kg}$$

$$\begin{aligned} P_4 = 500 \text{ kPa} \quad \left\{ \begin{aligned} h_4 &= h_f + x_4 h_{fg} = 640.09 + (0.90)(2108.0) = 2537.3 \text{ kJ/kg} \\ s_4 &= s_f + x_4 s_{fg} = 1.8604 + (0.90)(4.9603) = 6.3247 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_3 = 4000 \text{ kPa} \quad \left\{ \begin{aligned} h_3 &= 2939.4 \text{ kJ/kg} \\ s_3 &= s_4 \quad T_3 = \mathbf{292.2^\circ\text{C}} \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_6 = 10 \text{ kPa} \quad \left\{ \begin{aligned} h_6 &= h_f + x_6 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg} \\ s_6 &= s_f + x_6 s_{fg} = 0.6492 + (0.90)(7.4996) = 7.3989 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_5 = 500 \text{ kPa} \quad \left\{ \begin{aligned} h_5 &= 3029.2 \text{ kJ/kg} \\ s_5 &= s_6 \quad T_5 = \mathbf{282.9^\circ\text{C}} \end{aligned} \right. \end{aligned}$$

Thus,

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 2939.4 - 195.84 + 3029.2 - 2537.3 = 3235.4 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2344.7 - 191.81 = 2152.9 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2152.9}{3235.4} = \mathbf{0.335}$$

**10-39** An ideal reheat Rankine cycle with water as the working fluid is considered. The thermal efficiency of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_{f@50 \text{ kPa}} = 340.54 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@50 \text{ kPa}} = 0.001030 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(17500 - 50) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 17.97 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 340.54 + 17.97 = 358.51 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 17,500 \text{ kPa} \\ T_3 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3423.6 \text{ kJ/kg} \\ s_3 = 6.4266 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2000 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_4 = 2841.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 2000 \text{ kPa} \\ T_5 = 300^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3024.2 \text{ kJ/kg} \\ s_5 = 6.7684 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 50 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{aligned} x_6 &= \frac{s_6 - s_f}{s_{fg}} = \frac{6.7684 - 1.0912}{6.5019} = 0.8732 \\ h_6 &= h_f + x_6 h_{fg} = 340.54 + (0.8732)(2304.7) = 2352.9 \text{ kJ/kg} \end{aligned}$$

Thus,

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3423.6 - 358.51 + 3024.2 - 2841.5 = 3247.8 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2352.9 - 340.54 = 2012.4 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2012.4}{3247.8} = \mathbf{0.380}$$

**10-40** An ideal reheat Rankine cycle with water as the working fluid is considered. The thermal efficiency of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_{f@50 \text{ kPa}} = 340.54 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@50 \text{ kPa}} = 0.001030 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(17500 - 50) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 17.97 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 340.54 + 17.97 = 358.52 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 17,500 \text{ kPa} \\ T_3 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3423.6 \text{ kJ/kg} \\ s_3 = 6.4266 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2000 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_4 = 2841.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 2000 \text{ kPa} \\ T_5 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3579.0 \text{ kJ/kg} \\ s_5 = 7.5725 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 50 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.5725 - 1.0912}{6.5019} = 0.9968 \\ h_6 = h_f + x_6 h_{fg} = 340.54 + (0.9968)(2304.7) = 2638.0 \text{ kJ/kg} \end{array}$$

Thus,

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3423.6 - 358.52 + 3579.0 - 2841.5 = 3802.6 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2638.0 - 340.54 = 2297.4 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2297.4}{3802.6} = \mathbf{0.396}$$

The thermal efficiency was determined to be 0.380 when the temperature at the inlet of low-pressure turbine was 300°C. When this temperature is increased to 550°C, the thermal efficiency becomes 0.396. This corresponding to a percentage increase of 4.2% in thermal efficiency.

**10-41** A steam power plant that operates on an ideal reheat Rankine cycle between the specified pressure limits is considered. The pressure at which reheating takes place, the total rate of heat input in the boiler, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{\text{sat}@ 10 \text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_{\text{sat}@ 10 \text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.14 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$\begin{aligned} P_3 = 15 \text{ MPa} \quad & \left. \begin{aligned} h_3 &= 3310.8 \text{ kJ/kg} \\ T_3 = 500^\circ\text{C} \quad & s_3 = 6.3480 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_6 = 10 \text{ kPa} \quad & \left. \begin{aligned} h_6 &= h_f + x_6 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg} \\ s_6 = s_5 \quad & s_6 = s_f + x_6 s_{fg} = 0.6492 + (0.90)(7.4996) = 7.3988 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} T_5 = 500^\circ\text{C} \quad & \left. \begin{aligned} P_5 &= \mathbf{2150 \text{ kPa}} \text{ (the reheat pressure)} \\ s_5 = s_6 \quad & h_5 = 3466.61 \text{ kJ/kg} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_4 = 2.15 \text{ MPa} \quad & \left. \begin{aligned} h_4 &= 2817.2 \text{ kJ/kg} \\ s_4 = s_3 \quad & \end{aligned} \right\} \end{aligned}$$

(b) The rate of heat supply is

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}[(h_3 - h_2) + (h_5 - h_4)] \\ &= (12 \text{ kg/s})(3310.8 - 206.95 + 3466.61 - 2817.2) \text{ kJ/kg} = \mathbf{45,039 \text{ kW}} \end{aligned}$$

(c) The thermal efficiency is determined from

$$\dot{Q}_{\text{out}} = \dot{m}(h_6 - h_1) = (12 \text{ kg/s})(2344.7 - 191.81) \text{ kJ/kg} = 25,835 \text{ kJ/s}$$

Thus,

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{25,834 \text{ kJ/s}}{45,039 \text{ kJ/s}} = \mathbf{42.6\%}$$

**10-42** A steam power plant that operates on a reheat Rankine cycle is considered. The condenser pressure, the net power output, and the thermal efficiency are to be determined.

**Assumptions 1** Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

**Analysis (a)** From the steam tables (Tables A-4, A-5, and A-6),

$$\left. \begin{array}{l} P_3 = 12.5 \text{ MPa} \\ T_3 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3476.5 \text{ kJ/kg} \\ s_3 = 6.6317 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} h_{4s} = 2948.1 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$\begin{aligned} \rightarrow h_4 &= h_3 - \eta_T (h_3 - h_{4s}) \\ &= 3476.5 - (0.85)(3476.5 - 2948.1) \\ &= 3027.3 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{array}{l} P_5 = 2 \text{ MPa} \\ T_5 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3358.2 \text{ kJ/kg} \\ s_5 = 7.2815 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = ? \\ x_6 = 0.95 \end{array} \right\} h_6 =$$

$$\left. \begin{array}{l} P_6 = ? \\ s_6 = s_5 \end{array} \right\} h_{6s} =$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \rightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) \\ &= 3358.2 - (0.85)(3358.2 - 2948.1) \\ &= 3027.3 \text{ kJ/kg} \end{aligned}$$

The pressure at state 6 may be determined by a trial-error approach from the steam tables or by using EES from the above equations:

$$P_6 = \mathbf{9.73 \text{ kPa}}, \quad h_6 = 2463.3 \text{ kJ/kg},$$

(b) Then,

$$h_1 = h_f @ 9.73 \text{ kPa} = 189.57 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1 (P_2 - P_1) / \eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(12,500 - 9.73 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.90) \\ &= 14.02 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 189.57 + 14.02 = 203.59 \text{ kJ/kg}$$

Cycle analysis:

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3476.5 - 203.59 + 3358.2 - 2463.3 = 3603.8 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 3027.3 - 189.57 = 2273.7 \text{ kJ/kg}$$

$$\dot{W}_{\text{net}} = \dot{m}(q_{\text{in}} - q_{\text{out}}) = (7.7 \text{ kg/s})(3603.8 - 2273.7) \text{ kJ/kg} = \mathbf{10,242 \text{ kW}}$$

(c) The thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2273.7 \text{ kJ/kg}}{3603.8 \text{ kJ/kg}} = 0.369 = \mathbf{36.9\%}$$

## Regenerative Rankine Cycle

**10-43C** Moisture content remains the same, everything else decreases.

**10-44C** This is a smart idea because we waste little work potential but we save a lot from the heat input. The extracted steam has little work potential left, and most of its energy would be part of the heat rejected anyway. Therefore, by regeneration, we utilize a considerable amount of heat by sacrificing little work output.

**10-45C** In open feedwater heaters, the two fluids actually mix, but in closed feedwater heaters there is no mixing.

**10-46C** Both cycles would have the same efficiency.

**10-47C** To have the same thermal efficiency as the Carnot cycle, the cycle must receive and reject heat isothermally. Thus the liquid should be brought to the saturated liquid state at the boiler pressure isothermally, and the steam must be a saturated vapor at the turbine inlet. This will require an infinite number of heat exchangers (feedwater heaters), as shown on the  $T$ - $s$  diagram.

**10-48** Feedwater is heated by steam in a feedwater heater of a regenerative The required mass flow rate of the steam is to be determined.

**Assumptions** **1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** The device is adiabatic and thus heat transfer is negligible.

**Properties** From the steam tables (Tables A-4 through A-6 or EES),

$$h_1 \cong h_f @ 70^\circ\text{C} = 293.07 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 200 \text{ kPa} \\ T_2 = 160^\circ\text{C} \end{array} \right\} h_2 = 2789.7 \text{ kJ/kg}$$

$$h_3 = h_f @ 200 \text{ kPa} = 504.71 \text{ kJ/kg}$$

**Analysis** We take the mixing chamber as the system, which is a control volume since mass crosses the boundary. The mass and energy balances for this steady-flow system can be expressed in the rate form as

Mass balance:

$$\dot{m}_{\text{in}} - \dot{m}_{\text{out}} = \Delta \dot{m}_{\text{system}} \stackrel{\text{no}}{=} 0 \text{ (steady)} = 0$$

$$\dot{m}_{\text{in}} = \dot{m}_{\text{out}}$$

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$$

Energy balance:

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no}}{=} 0 \text{ (steady)} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \quad (\text{since } \dot{Q} = \dot{W} = \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = (\dot{m}_1 + \dot{m}_2) h_3$$

Solving for  $\dot{m}_2$ , and substituting gives

$$\dot{m}_2 = \dot{m}_1 \frac{h_1 - h_3}{h_3 - h_2} = (10 \text{ kg/s}) \frac{(293.07 - 504.71) \text{ kJ/kg}}{(504.71 - 2789.7) \text{ kJ/kg}} = \mathbf{0.926 \text{ kg/s}}$$

**10-49E** In a regenerative Rankine cycle, the closed feedwater heater with a pump as shown in the figure is arranged so that the water at state 5 is mixed with the water at state 2 to form a feedwater which is a saturated liquid. The mass flow rate of bleed steam required to operate this unit is to be determined.

**Assumptions** **1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** The device is adiabatic and thus heat transfer is negligible.

**Properties** From the steam tables (Tables A-4E through A-6E),

$$\left. \begin{array}{l} P_1 = 200 \text{ psia} \\ T_1 = 350^\circ\text{F} \end{array} \right\} h_1 \cong h_f @ 350^\circ\text{F} = 321.73 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ T_3 = 400^\circ\text{F} \end{array} \right\} h_3 = 1218.0 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_6 = 200 \text{ psia} \\ x_6 = 0 \end{array} \right\} h_6 = h_f @ 200 \text{ psia} = 355.46 \text{ Btu/lbm}$$

**Analysis** We take the entire unit as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\dot{\Delta E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{steady}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 + \dot{m}_3 w_{\text{P,in}} = \dot{m}_6 h_6$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 + \dot{m}_3 w_{\text{P,in}} = (\dot{m}_1 + \dot{m}_3) h_6$$

Solving this for  $\dot{m}_3$ ,

$$\dot{m}_3 = \dot{m}_1 \frac{h_6 - h_1}{(h_3 - h_6) + w_{\text{P,in}}} = (2 \text{ lbm/s}) \frac{355.46 - 321.73}{1218.0 - 355.46 + 0.1344} = \mathbf{0.0782 \text{ lbm/s}}$$

where

$$\begin{aligned} w_{\text{P,in}} &= \nu_4 (P_5 - P_4) = \nu_f @ 160 \text{ psia} (P_5 - P_4) \\ &= (0.01815 \text{ ft}^3/\text{lbm})(200 - 160) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) = 0.1344 \text{ Btu/lbm} \end{aligned}$$

**10-50E** The closed feedwater heater of a regenerative Rankine cycle is to heat feedwater to a saturated liquid. The required mass flow rate of bleed steam is to be determined.

**Assumptions** **1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** Heat loss from the device to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid.

**Properties** From the steam tables (Tables A-4E through A-6E),

$$\left. \begin{array}{l} P_1 = 400 \text{ psia} \\ T_1 = 370^\circ\text{F} \end{array} \right\} h_1 \cong h_f @ 370^\circ\text{F} = 342.88 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_2 = 400 \text{ psia} \\ x_2 = 0 \end{array} \right\} h_2 = h_f @ 400 \text{ psia} = 424.13 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 300 \text{ psia} \\ T_3 = 500^\circ\text{F} \end{array} \right\} h_3 = 1257.9 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_4 = 300 \text{ psia} \\ x_4 = 0 \end{array} \right\} h_4 = h_f @ 300 \text{ psia} = 393.94 \text{ Btu/lbm}$$

**Analysis** We take the heat exchanger as the system, which is a control volume. The mass and energy balances for this steady-flow system can be expressed in the rate form as

**Mass balance** (for each fluid stream):

$$\dot{m}_{\text{in}} - \dot{m}_{\text{out}} = \Delta \dot{m}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \rightarrow \dot{m}_{\text{in}} = \dot{m}_{\text{out}} \rightarrow \dot{m}_1 = \dot{m}_2 = \dot{m}_{fw} \text{ and } \dot{m}_3 = \dot{m}_4 = \dot{m}_s$$

**Energy balance** (for the heat exchanger):

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 = \dot{m}_2 h_2 + \dot{m}_4 h_4 \quad (\text{since } \dot{Q} = \dot{W} = \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

Combining the two,

$$\dot{m}_{fw}(h_2 - h_1) = \dot{m}_s(h_3 - h_4)$$

Solving for  $\dot{m}_s$ :

$$\dot{m}_s = \frac{h_2 - h_1}{h_3 - h_4} \dot{m}_{fw}$$

Substituting,

$$\dot{m}_s = \frac{424.13 - 342.88}{1257.9 - 393.94} (1 \text{ lbm/s}) = \mathbf{0.0940 \text{ lbm/s}}$$

**10-51** The closed feedwater heater of a regenerative Rankine cycle is to heat feedwater to a saturated liquid. The required mass flow rate of bleed steam is to be determined.

**Assumptions** **1** This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** Heat loss from the device to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid.

**Properties** From the steam tables (Tables A-4 through A-6),

$$\begin{aligned}
 & \left. \begin{aligned} P_1 &= 4000 \text{ kPa} \\ T_1 &= 200^\circ\text{C} \end{aligned} \right\} h_1 \cong h_f @ 200^\circ\text{C} = 852.26 \text{ kJ/kg} \\
 & \left. \begin{aligned} P_2 &= 4000 \text{ kPa} \\ T_2 &= 245^\circ\text{C} \end{aligned} \right\} h_2 \cong h_f @ 245^\circ\text{C} = 1061.5 \text{ kJ/kg} \\
 & \left. \begin{aligned} P_3 &= 3000 \text{ kPa} \\ x_3 &= 0.90 \end{aligned} \right\} h_3 = h_f + x_3 h_{fg} \\
 & \qquad \qquad \qquad = 1008.3 + (0.9)(1794.9) = 2623.7 \text{ kJ/kg} \\
 & \left. \begin{aligned} P_4 &= 3000 \text{ kPa} \\ x_4 &= 0 \end{aligned} \right\} h_4 = h_f @ 3000 \text{ kPa} = 1008.3 \text{ kJ/kg}
 \end{aligned}$$

**Analysis** We take the heat exchanger as the system, which is a control volume. The mass and energy balances for this steady-flow system can be expressed in the rate form as

*Mass balance* (for each fluid stream):

$$\dot{m}_{\text{in}} - \dot{m}_{\text{out}} = \Delta \dot{m}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \rightarrow \dot{m}_{\text{in}} = \dot{m}_{\text{out}} \rightarrow \dot{m}_1 = \dot{m}_2 = \dot{m}_{fw} \text{ and } \dot{m}_3 = \dot{m}_4 = \dot{m}_s$$

*Energy balance* (for the heat exchanger):

$$\begin{aligned}
 \underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} &= \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0 \\
 \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\
 \dot{m}_1 h_1 + \dot{m}_3 h_3 &= \dot{m}_2 h_2 + \dot{m}_4 h_4 \quad (\text{since } \dot{Q} = \dot{W} = \Delta \text{ke} \cong \Delta \text{pe} \cong 0)
 \end{aligned}$$

Combining the two,

$$\dot{m}_{fw} (h_2 - h_1) = \dot{m}_s (h_3 - h_4)$$

Solving for  $\dot{m}_s$ :

$$\dot{m}_s = \frac{h_2 - h_1}{h_3 - h_4} \dot{m}_{fw}$$

Substituting,

$$\dot{m}_s = \frac{1061.5 - 852.26}{2623.7 - 1008.3} (6 \text{ kg/s}) = \mathbf{0.777 \text{ kg/s}}$$

**10-52** A steam power plant operates on an ideal regenerative Rankine cycle with two open feedwater heaters. The net power output of the power plant and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis**

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned}
 h_1 &= h_{f@5 \text{ kPa}} = 137.75 \text{ kJ/kg} \\
 v_1 &= v_{f@5 \text{ kPa}} = 0.001005 \text{ m}^3/\text{kg} \\
 w_{pI,in} &= v_1(P_2 - P_1) = (0.001005 \text{ m}^3/\text{kg})(200 - 5 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.20 \text{ kJ/kg} \\
 h_2 &= h_1 + w_{pI,in} = 137.75 + 0.20 = 137.95 \text{ kJ/kg}
 \end{aligned}$$

$$\begin{aligned}
 P_3 &= 0.2 \text{ MPa} \left\{ \begin{aligned} h_3 &= h_{f@0.2 \text{ MPa}} = 504.71 \text{ kJ/kg} \\ \text{sat.liquid} \quad v_3 &= v_{f@0.2 \text{ MPa}} = 0.001061 \text{ m}^3/\text{kg} \end{aligned} \right.
 \end{aligned}$$

$$\begin{aligned}
 w_{pII,in} &= v_3(P_4 - P_3) = (0.001061 \text{ m}^3/\text{kg})(600 - 200 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\
 &= 0.42 \text{ kJ/kg}
 \end{aligned}$$

$$h_4 = h_3 + w_{pII,in} = 504.71 + 0.42 = 505.13 \text{ kJ/kg}$$

$$\begin{aligned}
 P_5 &= 0.6 \text{ MPa} \left\{ \begin{aligned} h_5 &= h_{f@0.6 \text{ MPa}} = 670.38 \text{ kJ/kg} \\ \text{sat.liquid} \quad v_5 &= v_{f@0.6 \text{ MPa}} = 0.001101 \text{ m}^3/\text{kg} \end{aligned} \right.
 \end{aligned}$$

$$\begin{aligned}
 w_{pIII,in} &= v_5(P_6 - P_5) = (0.001101 \text{ m}^3/\text{kg})(10,000 - 600 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\
 &= 10.35 \text{ kJ/kg}
 \end{aligned}$$

$$h_6 = h_5 + w_{pIII,in} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$\begin{aligned}
 P_7 &= 10 \text{ MPa} \left\{ \begin{aligned} h_7 &= 3625.8 \text{ kJ/kg} \\ T_7 &= 600^\circ\text{C} \quad s_7 = 6.9045 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right.
 \end{aligned}$$

$$\begin{aligned}
 P_8 &= 0.6 \text{ MPa} \left\{ \begin{aligned} h_8 &= 2821.8 \text{ kJ/kg} \\ s_8 &= s_7 \end{aligned} \right.
 \end{aligned}$$

$$\begin{aligned}
 P_9 = 0.2 \text{ MPa} \quad \left\{ \begin{aligned} x_9 &= \frac{s_9 - s_f}{s_{fg}} = \frac{6.9045 - 1.5302}{5.5968} = 0.9602 \\ s_9 &= s_7 \end{aligned} \right. \\
 h_9 = h_f + x_9 h_{fg} = 504.71 + (0.9602)(2201.6) = 2618.7 \text{ kJ/kg}
 \end{aligned}$$

$$\begin{aligned}
 P_{10} = 5 \text{ kPa} \quad \left\{ \begin{aligned} x_{10} &= \frac{s_{10} - s_f}{s_{fg}} = \frac{6.9045 - 0.4762}{7.9176} = 0.8119 \\ s_{10} &= s_7 \end{aligned} \right. \\
 h_{10} = h_f + x_{10} h_{fg} = 137.75 + (0.8119)(2423.0) = 2105.0 \text{ kJ/kg}
 \end{aligned}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that  $\dot{Q} \cong \dot{W} \cong \Delta \text{ke} \cong \Delta \text{pe} \cong 0$ ,

FWH-2:

$$\begin{aligned}
 \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \quad \phi^0(\text{steady}) = 0 \\
 \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\
 \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_4 h_4 = \dot{m}_5 h_5 \longrightarrow y h_8 + (1-y) h_4 = 1(h_5)
 \end{aligned}$$

where  $y$  is the fraction of steam extracted from the turbine ( $= \dot{m}_8 / \dot{m}_5$ ). Solving for  $y$ ,

$$y = \frac{h_5 - h_4}{h_8 - h_4} = \frac{670.38 - 505.13}{2821.8 - 505.13} = 0.07133$$

FWH-1:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_9 h_9 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow z h_9 + (1-y-z) h_2 = (1-y) h_3$$

where  $z$  is the fraction of steam extracted from the turbine ( $= \dot{m}_9 / \dot{m}_5$ ) at the second stage. Solving for  $z$ ,

$$z = \frac{h_3 - h_2}{h_9 - h_2} (1-y) = \frac{504.71 - 137.95}{2618.7 - 137.95} (1 - 0.07136) = 0.1373$$

Then,

$$\begin{aligned}
 q_{\text{in}} &= h_7 - h_6 = 3625.8 - 680.73 = 2945.0 \text{ kJ/kg} \\
 q_{\text{out}} &= (1-y-z)(h_{10} - h_1) = (1 - 0.07133 - 0.1373)(2105.0 - 137.75) = 1556.8 \text{ kJ/kg} \\
 w_{\text{net}} &= q_{\text{in}} - q_{\text{out}} = 2945.0 - 1556.8 = 1388.2 \text{ kJ/kg}
 \end{aligned}$$

and

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (22 \text{ kg/s})(1388.2 \text{ kJ/kg}) = 30,540 \text{ kW} \cong \mathbf{30.5 \text{ MW}}$$

$$(b) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1556.8 \text{ kJ/kg}}{2945.0 \text{ kJ/kg}} = \mathbf{47.1\%}$$

**10-53 [Also solved by EES on enclosed CD]** A steam power plant operates on an ideal regenerative Rankine cycle with two feedwater heaters, one closed and one open. The mass flow rate of steam through the boiler for a net power output of 250 MW and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(300 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.29 \text{ kJ/kg} \\ h_2 &= h_1 + w_{pI, \text{in}} = 191.81 + 0.29 = 192.10 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} P_3 = 0.3 \text{ MPa} \quad & \left\{ \begin{aligned} h_3 &= h_f @ 0.3 \text{ MPa} = 561.43 \text{ kJ/kg} \\ \nu_3 &= \nu_f @ 0.3 \text{ MPa} = 0.001073 \text{ m}^3/\text{kg} \end{aligned} \right. \\ \text{sat. liquid} \quad & \end{aligned}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_3 (P_4 - P_3) \\ &= (0.001073 \text{ m}^3/\text{kg})(12,500 - 300 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 13.09 \text{ kJ/kg} \\ h_4 &= h_3 + w_{pII, \text{in}} = 561.43 + 13.09 = 574.52 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} P_6 = 0.8 \text{ MPa} \quad & \left\{ \begin{aligned} h_6 &= h_7 = h_f @ 0.8 \text{ MPa} = 720.87 \text{ kJ/kg} \\ \nu_6 &= \nu_f @ 0.8 \text{ MPa} = 0.001115 \text{ m}^3/\text{kg} \\ T_6 &= T_{\text{sat}} @ 0.8 \text{ MPa} = 170.4^\circ\text{C} \end{aligned} \right. \\ \text{sat. liquid} \quad & \end{aligned}$$

$$T_6 = T_5, \quad P_5 = 12.5 \text{ MPa} \rightarrow h_5 = 727.83 \text{ kJ/kg}$$

$$\begin{aligned} P_8 = 12.5 \text{ MPa} \quad & \left\{ \begin{aligned} h_8 &= 3476.5 \text{ kJ/kg} \\ T_8 &= 550^\circ\text{C} \end{aligned} \right. \\ & \left\{ \begin{aligned} s_8 &= 6.6317 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_9 = 0.8 \text{ MPa} \quad & \left\{ \begin{aligned} x_9 &= \frac{s_9 - s_f}{s_{fg}} = \frac{6.6317 - 2.0457}{4.6160} = 0.9935 \\ s_9 = s_8 \quad & \left\{ \begin{aligned} h_9 &= h_f + x_9 h_{fg} = 720.87 + (0.9935)(2047.5) = 2755.0 \text{ kJ/kg} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_{10} = 0.3 \text{ MPa} \quad & \left\{ \begin{aligned} x_{10} &= \frac{s_{10} - s_f}{s_{fg}} = \frac{6.6317 - 1.6717}{5.3200} = 0.9323 \\ s_{10} = s_8 \quad & \left\{ \begin{aligned} h_{10} &= h_f + x_{10} h_{fg} = 561.43 + (0.9323)(2163.5) = 2578.5 \text{ kJ/kg} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_{11} = 10 \text{ kPa} \quad & \left\{ \begin{aligned} x_{11} &= \frac{s_{11} - s_f}{s_{fg}} = \frac{6.6317 - 0.6492}{7.4996} = 0.7977 \\ s_{11} = s_8 \quad & \left\{ \begin{aligned} h_{11} &= h_f + x_{11} h_{fg} = 191.81 + (0.7977)(2392.1) = 2100.0 \text{ kJ/kg} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that  $\dot{Q} \cong \dot{W} \cong \Delta \text{pe} \cong 0$ ,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_9 (h_9 - h_6) = \dot{m}_5 (h_5 - h_4) \longrightarrow y(h_9 - h_6) = (h_5 - h_4)$$

where  $y$  is the fraction of steam extracted from the turbine ( $= \dot{m}_{10} / \dot{m}_5$ ). Solving for  $y$ ,

$$y = \frac{h_5 - h_4}{h_9 - h_6} = \frac{727.83 - 574.52}{2755.0 - 720.87} = 0.0753$$

For the open FWH,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_7 h_7 + \dot{m}_2 h_2 + \dot{m}_{10} h_{10} = \dot{m}_3 h_3 \longrightarrow y h_7 + (1 - y - z) h_2 + z h_{10} = (1) h_3$$

where  $z$  is the fraction of steam extracted from the turbine ( $= \dot{m}_9 / \dot{m}_5$ ) at the second stage. Solving for  $z$ ,

$$z = \frac{(h_3 - h_2) - y(h_7 - h_2)}{h_{10} - h_2} = \frac{561.43 - 192.10 - (0.0753)(720.87 - 192.10)}{2578.5 - 192.10} = 0.1381$$

Then,

$$q_{\text{in}} = h_8 - h_5 = 3476.5 - 727.36 = 2749.1 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y - z)(h_{11} - h_1) = (1 - 0.0753 - 0.1381)(2100.0 - 191.81) = 1500.1 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2749.1 - 1500.1 = 1249 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{250,000 \text{ kJ/s}}{1249 \text{ kJ/kg}} = \mathbf{200.2 \text{ kg/s}}$$

$$(b) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1500.1 \text{ kJ/kg}}{2749.1 \text{ kJ/kg}} = \mathbf{45.4\%}$$

**10-54 EES** Problem 10-53 is reconsidered. The effects of turbine and pump efficiencies on the mass flow rate and thermal efficiency are to be investigated. Also, the  $T$ - $s$  diagram is to be plotted.

**Analysis** The problem is solved using EES, and the solution is given below.

**10-55** An ideal regenerative Rankine cycle with a closed feedwater heater is considered. The work produced by the turbine, the work consumed by the pumps, and the heat added in the boiler are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= \nu_1 (P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.03 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 251.42 + 3.03 = 254.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 1000 \text{ kPa} \\ s_5 = s_4 \end{array} \right\} h_5 = 2851.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_6 = s_4 \end{array} \right\} \begin{aligned} x_6 &= \frac{s_6 - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_6 &= h_f + x_6 h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{aligned}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{array}{l} P_7 = 1000 \text{ kPa} \\ x_7 = 0 \end{array} \right\} \begin{array}{l} h_7 = 762.51 \text{ kJ/kg} \\ T_7 = 179.9^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 209.9^\circ\text{C} \end{array} \right\} h_3 = 763.53 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ( $= \dot{m}_5 / \dot{m}_4$ ) for closed feedwater heater:

$$\begin{aligned}\sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_5 h_5 + \dot{m}_2 h_2 &= \dot{m}_3 h_3 + \dot{m}_7 h_7 \\ y h_5 + 1 h_2 &= 1 h_3 + y h_7\end{aligned}$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 254.45}{2851.9 - 762.51} = 0.2437$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2851.9 + (1 - 0.2437)(2851.9 - 2221.7) = \mathbf{740.9 \text{ kJ/kg}}$$

$$w_{P,\text{in}} = \mathbf{3.03 \text{ kJ/kg}}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = \mathbf{2353 \text{ kJ/kg}}$$

Also,

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 740.9 - 3.03 = 737.8 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{737.8}{2353} = 0.3136$$

**10-56** An ideal regenerative Rankine cycle with a closed feedwater heater is considered. The change in thermal efficiency when the steam serving the closed feedwater heater is extracted at 600 kPa rather than 1000 kPa is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= \nu_1 (P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.03 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 251.42 + 3.03 = 254.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 600 \text{ kPa} \\ s_5 = s_4 \end{array} \right\} \begin{array}{l} x_5 = \frac{s_5 - s_f}{s_{fg}} = \frac{6.7450 - 1.9308}{4.8285} = 0.9970 \\ h_5 = h_f + x_5 h_{fg} = 670.38 + (0.9970)(2085.8) = 2750.0 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_6 = s_4 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_6 = h_f + x_6 h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{array}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{array}{l} P_7 = 600 \text{ kPa} \\ x_7 = 0 \end{array} \right\} \begin{array}{l} h_7 = 670.38 \text{ kJ/kg} \\ T_7 = 158.8^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 158.8^\circ\text{C} \end{array} \right\} h_3 = 671.79 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ( $= \dot{m}_5 / \dot{m}_4$ ) for closed feedwater heater:

$$\begin{aligned}\sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_5 h_5 + \dot{m}_2 h_2 &= \dot{m}_3 h_3 + \dot{m}_7 h_7 \\ y h_5 + 1 h_2 &= 1 h_3 + y h_7\end{aligned}$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{671.79 - 254.45}{2750.0 - 670.38} = 0.2007$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2750.0 + (1 - 0.2007)(2750.0 - 2221.7) = 788.4 \text{ kJ/kg}$$

$$w_{P,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 671.79 = 2444 \text{ kJ/kg}$$

Also,

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 788.4 - 3.03 = 785.4 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{785.4}{2444} = \mathbf{0.3213}$$

When the steam serving the closed feedwater heater is extracted at 600 kPa rather than 1000 kPa, the thermal efficiency increases from **0.3136** to **0.3213**. This is an increase of **2.5%**.

**10-57 EES** The optimum bleed pressure for the open feedwater heater that maximizes the thermal efficiency of the cycle is to be determined by EES.

**Analysis** The EES program used to solve this problem as well as the solutions are given below.

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ( $= \dot{m}_5 / \dot{m}_4$ ) for closed feedwater heater:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_5 h_5 + \dot{m}_2 h_2 = \dot{m}_3 h_3 + \dot{m}_7 h_7$$

$$y h_5 + 1 h_2 = 1 h_3 + y h_7$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 254.45}{2878.3 - 762.51} = 0.2406$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2878.3 + (1 - 0.2406)(2878.3 - 2311.1) = 668.5 \text{ kJ/kg}$$

$$w_{P,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also,

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 668.5 - 3.03 = 665.5 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{665.5}{2353} = \mathbf{0.2829}$$

**10-59** A regenerative Rankine cycle with a closed feedwater heater is considered. The thermal efficiency is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6 or EES),

When the liquid enters the pump  $10^\circ\text{C}$  cooler than a saturated liquid at the condenser pressure, the enthalpies become

$$\left. \begin{array}{l} P_1 = 20 \text{ kPa} \\ T_1 = T_{\text{sat @ } 20 \text{ kPa}} - 10 = 60.06 - 10 \cong 50^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 \cong h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg} \\ v_1 \cong v_f @ 50^\circ\text{C} = 0.001012 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1 (P_2 - P_1) \\ &= (0.001012 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.02 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 209.34 + 3.02 = 212.36 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 1000 \text{ kPa} \\ s_{5s} = s_4 \end{array} \right\} h_{5s} = 2851.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_{6s} = s_4 \end{array} \right\} \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_{6s} = h_f + x_{6s} h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T (h_4 - h_{5s}) = 3116.1 - (0.90)(3116.1 - 2851.9) = 2878.3 \text{ kJ/kg}$$

$$\eta_T = \frac{h_4 - h_6}{h_4 - h_{6s}} \longrightarrow h_6 = h_4 - \eta_T (h_4 - h_{6s}) = 3116.1 - (0.90)(3116.1 - 2221.7) = 2311.1 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{array}{l} P_7 = 1000 \text{ kPa} \\ x_7 = 0 \end{array} \right\} \begin{array}{l} h_7 = 762.51 \text{ kJ/kg} \\ T_7 = 179.9^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 209.9^\circ\text{C} \end{array} \right\} h_3 = 763.53 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ( $= \dot{m}_5 / \dot{m}_4$ ) for closed feedwater heater:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_5 h_5 + \dot{m}_2 h_2 = \dot{m}_3 h_3 + \dot{m}_7 h_7$$

$$y h_5 + 1 h_2 = 1 h_3 + y h_7$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 212.36}{2878.3 - 762.51} = 0.2605$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2878.3 + (1 - 0.2605)(2878.3 - 2311.1) = 657.2 \text{ kJ/kg}$$

$$w_{P,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also,

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 657.2 - 3.03 = 654.2 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{654.2}{2353} = \mathbf{0.2781}$$

**10-60 EES** The effect of pressure drop and non-isentropic turbine on the rate of heat input is to be determined for a given power plant.

**Analysis** The EES program used to solve this problem as well as the solutions are given below.

**10-61E** A steam power plant operates on an ideal reheat-regenerative Rankine cycle with one reheater and two open feedwater heaters. The mass flow rate of steam through the boiler, the net power output of the plant, and the thermal efficiency of the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis**

(a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 1 \text{ psia} = 69.72 \text{ Btu/lbm}$$

$$\nu_1 = \nu_f @ 1 \text{ psia} = 0.01614 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.01614 \text{ ft}^3/\text{lbm})(40 - 1 \text{ psia}) \left( \frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.12 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 69.72 + 0.12 = 69.84 \text{ Btu/lbm}$$

$$\begin{aligned} P_3 = 40 \text{ psia} \quad & \left. \begin{aligned} h_3 &= h_f @ 40 \text{ psia} = 236.14 \text{ Btu/lbm} \\ \nu_3 &= \nu_f @ 40 \text{ psia} = 0.01715 \text{ ft}^3/\text{lbm} \end{aligned} \right\} \begin{aligned} & \text{sat. liquid} \end{aligned} \end{aligned}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_3 (P_4 - P_3) \\ &= (0.01715 \text{ ft}^3/\text{lbm})(250 - 40 \text{ psia}) \left( \frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.67 \text{ Btu/lbm} \end{aligned}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 236.14 + 0.67 = 236.81 \text{ Btu/lbm}$$

$$\begin{aligned} P_5 = 250 \text{ psia} \quad & \left. \begin{aligned} h_5 &= h_f @ 250 \text{ psia} = 376.09 \text{ Btu/lbm} \\ \nu_5 &= \nu_f @ 250 \text{ psia} = 0.01865 \text{ ft}^3/\text{lbm} \end{aligned} \right\} \begin{aligned} & \text{sat. liquid} \end{aligned} \end{aligned}$$

$$\begin{aligned} w_{pIII, \text{in}} &= \nu_5 (P_6 - P_5) \\ &= (0.01865 \text{ ft}^3/\text{lbm})(1500 - 250 \text{ psia}) \left( \frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 4.31 \text{ Btu/lbm} \end{aligned}$$

$$h_6 = h_5 + w_{pIII, \text{in}} = 376.09 + 4.31 = 380.41 \text{ Btu/lbm}$$

$$\begin{aligned} P_7 = 1500 \text{ psia} \quad & \left. \begin{aligned} h_7 &= 1550.5 \text{ Btu/lbm} \\ T_7 &= 1100^\circ\text{F} \end{aligned} \right\} s_7 = 1.6402 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\begin{aligned} P_8 = 250 \text{ psia} \quad & \left. \begin{aligned} h_8 &= 1308.5 \text{ Btu/lbm} \\ s_8 &= s_7 \end{aligned} \right\} \end{aligned}$$

$$\left. \begin{array}{l} P_9 = 140 \text{ psia} \\ s_9 = s_7 \end{array} \right\} h_9 = 1248.8 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_{10} = 140 \text{ psia} \\ T_{10} = 1000^\circ\text{F} \end{array} \right\} \begin{array}{l} h_{10} = 1531.3 \text{ Btu/lbm} \\ s_{10} = 1.8832 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_{11} = 40 \text{ psia} \\ s_{11} = s_{10} \end{array} \right\} h_{11} = 1356.0 \text{ Btu/lbm}$$

$$x_{12} = \frac{s_{12} - s_f}{s_{fg}} = \frac{1.8832 - 0.13262}{1.84495} = 0.9488$$

$$\left. \begin{array}{l} P_{12} = 1 \text{ psia} \\ s_{12} = s_{10} \end{array} \right\} \begin{array}{l} h_{12} = h_f + x_{12} h_{fg} = 69.72 + (0.9488)(1035.7) \\ \quad = 1052.4 \text{ Btu/lbm} \end{array}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that  $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ ,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{\cong} 0$$

FWH-2:

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_4 h_4 = \dot{m}_5 h_5 \longrightarrow y h_8 + (1-y) h_4 = 1(h_5)$$

where  $y$  is the fraction of steam extracted from the turbine ( $= \dot{m}_8 / \dot{m}_5$ ). Solving for  $y$ ,

$$y = \frac{h_5 - h_4}{h_8 - h_4} = \frac{376.09 - 236.81}{1308.5 - 236.81} = 0.1300$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{\cong} 0$$

FWH-1

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_{11} h_{11} + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow z h_{11} + (1-y-z) h_2 = (1-y) h_3$$

where  $z$  is the fraction of steam extracted from the turbine ( $= \dot{m}_9 / \dot{m}_5$ ) at the second stage. Solving for  $z$ ,

$$z = \frac{h_3 - h_2}{h_{11} - h_2} (1-y) = \frac{236.14 - 69.84}{1356.0 - 69.84} (1 - 0.1300) = 0.1125$$

Then,

$$q_{\text{in}} = h_7 - h_6 + (1-y)(h_{10} - h_9) = 1550.5 - 380.41 + (1 - 0.1300)(1531.3 - 1248.8) = 1415.8 \text{ Btu/lbm}$$

$$q_{\text{out}} = (1-y-z)(h_{12} - h_1) = (1 - 0.1300 - 0.1125)(1052.4 - 69.72) = 744.4 \text{ Btu/lbm}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1415.8 - 744.4 = 671.4 \text{ Btu/lbm}$$

and

$$\dot{m} = \frac{\dot{Q}_{\text{in}}}{q_{\text{in}}} = \frac{4 \times 10^5 \text{ Btu/s}}{1415.8 \text{ Btu/lbm}} = \mathbf{282.5 \text{ lbm/s}}$$

$$(b) \quad \dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (282.5 \text{ lbm/s})(671.4 \text{ Btu/lbm}) \left( \frac{1.055 \text{ kJ}}{1 \text{ Btu}} \right) = \mathbf{200.1 \text{ MW}}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{744.4 \text{ Btu/lbm}}{1415.8 \text{ Btu/lbm}} = \mathbf{47.4\%}$$

**10-62** A steam power plant that operates on an ideal regenerative Rankine cycle with a closed feedwater heater is considered. The temperature of the steam at the inlet of the closed feedwater heater, the mass flow rate of the steam extracted from the turbine for the closed feedwater heater, the net power output, and the thermal efficiency are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@20 \text{ kPa}} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@20 \text{ kPa}} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{pI,in} = \nu_1(P_2 - P_1)/\eta_p$$

$$= (0.001017 \text{ m}^3/\text{kg})(12,500 - 20 \text{ kPa}) \frac{1}{0.88}$$

$$= 14.43 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,in}$$

$$= 251.42 + 14.43$$

$$= 265.85 \text{ kJ/kg}$$

$$P_3 = 1 \text{ MPa} \left\{ \begin{array}{l} h_3 = h_{f@1 \text{ MPa}} = 762.51 \text{ kJ/kg} \\ \nu_3 = \nu_{f@1 \text{ MPa}} = 0.001127 \text{ m}^3/\text{kg} \end{array} \right.$$

$$\text{sat. liquid} \left\{ \begin{array}{l} \nu_3 = \nu_{f@1 \text{ MPa}} = 0.001127 \text{ m}^3/\text{kg} \end{array} \right.$$

$$w_{pII,in} = \nu_3(P_{11} - P_3)/\eta_p$$

$$= (0.001127 \text{ m}^3/\text{kg})(12,500 - 1000 \text{ kPa})/0.88$$

$$= 14.73 \text{ kJ/kg}$$

$$h_{11} = h_3 + w_{pII,in} = 762.51 + 14.73 = 777.25 \text{ kJ/kg}$$

Also,  $h_4 = h_{10} = h_{11} = 777.25 \text{ kJ/kg}$  since the two fluid streams which are being mixed have the same enthalpy.

$$P_5 = 12.5 \text{ MPa} \left\{ \begin{array}{l} h_5 = 3476.5 \text{ kJ/kg} \\ T_5 = 550^\circ\text{C} \end{array} \right\} s_5 = 6.6317 \text{ kJ/kg} \cdot \text{K}$$

$$P_6 = 5 \text{ MPa} \left\{ \begin{array}{l} h_{6s} = 3185.6 \text{ kJ/kg} \\ s_6 = s_5 \end{array} \right.$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s})$$

$$= 3476.5 - (0.88)(3476.5 - 3185.6) = 3220.5 \text{ kJ/kg}$$

$$P_7 = 5 \text{ MPa} \left\{ \begin{array}{l} h_7 = 3550.9 \text{ kJ/kg} \\ T_7 = 550^\circ\text{C} \end{array} \right\} s_7 = 7.1238 \text{ kJ/kg} \cdot \text{K}$$

$$P_8 = 1 \text{ MPa} \left\{ \begin{array}{l} h_{8s} = 3051.1 \text{ kJ/kg} \\ s_8 = s_7 \end{array} \right.$$

$$\eta_T = \frac{h_7 - h_8}{h_7 - h_{8s}} \longrightarrow h_8 = h_7 - \eta_T(h_7 - h_{8s})$$

$$= 3550.9 - (0.88)(3550.9 - 3051.1) = 3111.1 \text{ kJ/kg}$$

$$P_8 = 1 \text{ MPa} \left\{ \begin{array}{l} h_8 = 3111.1 \text{ kJ/kg} \\ T_8 = 328^\circ\text{C} \end{array} \right.$$

$$\left. \begin{array}{l} P_9 = 20 \text{ kPa} \\ s_9 = s_7 \end{array} \right\} h_{9s} = 2347.9 \text{ kJ/kg}$$

$$\eta_T = \frac{h_7 - h_9}{h_7 - h_{9s}} \longrightarrow h_9 = h_7 - \eta_T (h_7 - h_{9s})$$

$$= 3550.9 - (0.88)(3550.9 - 2347.9) = 2492.2 \text{ kJ/kg}$$

The fraction of steam extracted from the low pressure turbine for closed feedwater heater is determined from the steady-flow energy balance equation applied to the feedwater heater. Noting that

$$\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0,$$

$$(1-y)(h_{10} - h_2) = y(h_8 - h_3)$$

$$(1-y)(777.25 - 265.85) = y(3111.1 - 762.51) \longrightarrow y = 0.1788$$

The corresponding mass flow rate is

$$\dot{m}_8 = y\dot{m}_5 = (0.1788)(24 \text{ kg/s}) = \mathbf{4.29 \text{ kg/s}}$$

(c) Then,

$$q_{\text{in}} = h_5 - h_4 + h_7 - h_6 = 3476.5 - 777.25 + 3550.9 - 3220.5 = 3029.7 \text{ kJ/kg}$$

$$q_{\text{out}} = (1-y)(h_9 - h_1) = (1-0.1788)(2492.2 - 251.42) = 1840.1 \text{ kJ/kg}$$

and

$$\dot{W}_{\text{net}} = \dot{m}(q_{\text{in}} - q_{\text{out}}) = (24 \text{ kg/s})(3029.7 - 1840.1) \text{ kJ/kg} = \mathbf{28,550 \text{ kW}}$$

(b) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1840.1 \text{ kJ/kg}}{3029.7 \text{ kJ/kg}} = 0.393 = \mathbf{39.3\%}$$

## Second-Law Analysis of Vapor Power Cycles

**10-63C** In the simple ideal Rankine cycle, irreversibilities occur during heat addition and heat rejection processes in the boiler and the condenser, respectively, and both are due to temperature difference. Therefore, the irreversibilities can be decreased and thus the 2<sup>nd</sup> law efficiency can be increased by minimizing the temperature differences during heat transfer in the boiler and the condenser. One way of doing that is regeneration.

**10-64** The exergy destruction associated with the heat rejection process in Prob. 10-25 is to be determined for the specified source and sink temperatures. The exergy of the steam at the boiler exit is also to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Problem 10-25,

$$\begin{aligned}s_1 &= s_2 = s_{f@10\text{kPa}} = 0.6492 \text{ kJ/kg} \cdot \text{K} \\s_3 &= s_4 = 6.8000 \text{ kJ/kg} \cdot \text{K} \\h_3 &= 3411.4 \text{ kJ/kg} \\q_{\text{out}} &= 1961.8 \text{ kJ/kg}\end{aligned}$$

The exergy destruction associated with the heat rejection process is

$$x_{\text{destroyed},41} = T_0 \left( s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = (290 \text{ K}) \left( 0.6492 - 6.8000 + \frac{1961.8 \text{ kJ/kg}}{290 \text{ K}} \right) = \mathbf{178.0 \text{ kJ/kg}}$$

The exergy of the steam at the boiler exit is simply the flow exergy,

$$\begin{aligned}\psi_3 &= (h_3 - h_0) - T_0(s_3 - s_0) + \frac{\mathbf{v}_3^2}{2} \approx 0 + qz_3 \approx 0 \\&= (h_3 - h_0) - T_0(s_3 - s_0)\end{aligned}$$

where

$$\begin{aligned}h_0 &= h_{@ (290 \text{ K}, 100 \text{ kPa})} \cong h_f @ 290 \text{ K} = 71.95 \text{ kJ/kg} \\s_0 &= s_{@ (290 \text{ K}, 100 \text{ kPa})} \cong s_f @ 290 \text{ K} = 0.2533 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

Thus,

$$\psi_3 = (3411.4 - 71.95) \text{ kJ/kg} - (290 \text{ K})(6.800 - 0.2532) \text{ kJ/kg} \cdot \text{K} = \mathbf{1440.9 \text{ kJ/kg}}$$

**10-65E** The exergy destructions associated with each of the processes of the Rankine cycle described in Prob. 10-15E are to be determined for the specified source and sink temperatures.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Problem 10-15E,

$$s_1 = s_2 = s_f @ 6 \text{ psia} = 0.24739 \text{ Btu/lbm} \cdot \text{R}$$

$$s_3 = s_4 = 1.8075 \text{ Btu/lbm} \cdot \text{R}$$

$$q_{\text{in}} = h_3 - h_2 = 1630.0 - 139.52 = 1490.5 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_2 = 1120.4 - 138.02 = 982.38 \text{ Btu/lbm}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed}, 23} = T_0 \left( s_3 - s_2 - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (500 \text{ R}) \left( 1.8075 - 0.24739 - \frac{1490.5 \text{ Btu/lbm}}{1960 \text{ R}} \right) = \mathbf{399.8 \text{ Btu/lbm}}$$

$$x_{\text{destroyed}, 41} = T_0 \left( s_1 - s_4 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (500 \text{ R}) \left( 0.24739 - 1.8075 + \frac{982.38 \text{ Btu/lbm}}{500 \text{ R}} \right) = \mathbf{202.3 \text{ Btu/lbm}}$$

Processes 1-2 and 3-4 are isentropic, and thus

$$x_{\text{destroyed}, 12} = \mathbf{0}$$

$$x_{\text{destroyed}, 34} = \mathbf{0}$$

**10-66** The exergy destructions associated with each of the processes of the Rankine cycle described in Prob. 10-17 are to be determined for the specified source and sink temperatures.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Problem 10-17,

$$s_1 = s_2 = s_f @ 20 \text{ kPa} = 0.8320 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_4 = 7.6214 \text{ kJ/kg} \cdot \text{K}$$

$$q_{\text{in}} = h_3 - h_2 = 3906.3 - 255.47 = 3650.8 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2513.7 - 251.42 = 2262.3 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed}, 23} = T_0 \left( s_3 - s_2 - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (288 \text{ K}) \left( 7.6214 - 0.8320 - \frac{3650.8 \text{ kJ/kg}}{1023 \text{ K}} \right) = \mathbf{927.6 \text{ kJ/kg}}$$

$$x_{\text{destroyed}, 41} = T_0 \left( s_1 - s_4 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (288 \text{ K}) \left( 0.8320 - 7.6214 + \frac{2262.3 \text{ kJ/kg}}{288 \text{ K}} \right) = \mathbf{307.0 \text{ kJ/kg}}$$

Processes 1-2 and 3-4 are isentropic, and thus

$$x_{\text{destroyed}, 12} = \mathbf{0}$$

$$x_{\text{destroyed}, 34} = \mathbf{0}$$

**10-67E** The exergy destructions associated with each of the processes of the ideal reheat Rankine cycle described in Prob. 10-36E are to be determined for the specified source and sink temperatures.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Problem 10-36E,

$$s_1 = s_2 = s_f @ 10 \text{ psia} = 0.28362 \text{ Btu/lbm} \cdot \text{R}$$

$$s_3 = s_4 = 1.5325 \text{ Btu/lbm} \cdot \text{R}$$

$$s_5 = s_6 = 1.6771 \text{ Btu/lbm} \cdot \text{R}$$

$$q_{\text{in},2-3} = h_3 - h_2 = 1289.9 - 163.06 = 1126.8 \text{ Btu/lbm}$$

$$q_{\text{in},4-5} = h_5 - h_4 = 1322.3 - 1187.5 = 134.8 \text{ Btu/lbm}$$

$$q_{\text{out}} = 909.7 \text{ Btu/lbm}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed},23} = T_0 \left( s_3 - s_2 - \frac{q_{\text{in},2-3}}{T_{\text{source}}} \right) = (537 \text{ R}) \left( 1.5325 - 0.28362 - \frac{1126.8 \text{ Btu/lbm}}{1160 \text{ R}} \right) = \mathbf{149.0 \text{ Btu/lbm}}$$

$$x_{\text{destroyed},45} = T_0 \left( s_5 - s_4 - \frac{q_{\text{in},4-5}}{T_{\text{source}}} \right) = (537 \text{ R}) \left( 1.6771 - 1.5325 - \frac{134.8 \text{ Btu/lbm}}{1160 \text{ R}} \right) = \mathbf{15.2 \text{ Btu/lbm}}$$

$$x_{\text{destroyed},61} = T_0 \left( s_1 - s_6 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (537 \text{ R}) \left( 0.28362 - 1.6771 + \frac{909.7 \text{ Btu/lbm}}{537 \text{ R}} \right) = \mathbf{161.4 \text{ Btu/lbm}}$$

Processes 1-2, 3-4, and 5-6 are isentropic, and thus,

$$x_{\text{destroyed},12} = \mathbf{0}$$

$$x_{\text{destroyed},34} = \mathbf{0}$$

$$x_{\text{destroyed},56} = \mathbf{0}$$

**10-68** The exergy destructions associated with each of the processes of the reheat Rankine cycle described in Prob. 10-34 are to be determined for the specified source and sink temperatures.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Problem 10-34,

$$s_1 = s_2 = s_{f@20\text{kPa}} = 0.8320 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_4 = 6.7266 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = s_6 = 7.2359 \text{ kJ/kg} \cdot \text{K}$$

$$q_{23,\text{in}} = 3399.5 - 259.54 = 3140.0 \text{ kJ/kg}$$

$$q_{45,\text{in}} = 3457.2 - 3105.1 = 352.1 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2385.2 - 251.42 = 2133.8 \text{ kJ/kg}$$

Processes 1-2, 3-4, and 5-6 are isentropic. Thus,  $i_{12} = i_{34} = i_{56} = 0$ . Also,

$$x_{\text{destroyed},23} = T_0 \left( s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = (300 \text{ K}) \left( 6.7266 - 0.8320 + \frac{-3140.0 \text{ kJ/kg}}{1800 \text{ K}} \right) = \mathbf{1245.0 \text{ kJ/kg}}$$

$$x_{\text{destroyed},45} = T_0 \left( s_5 - s_4 + \frac{q_{R,45}}{T_R} \right) = (300 \text{ K}) \left( 7.2359 - 6.7266 + \frac{-352.5 \text{ kJ/kg}}{1800 \text{ K}} \right) = \mathbf{94.1 \text{ kJ/kg}}$$

$$x_{\text{destroyed},61} = T_0 \left( s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = (300 \text{ K}) \left( 0.8320 - 7.2359 + \frac{2133.8 \text{ kJ/kg}}{300 \text{ K}} \right) = \mathbf{212.6 \text{ kJ/kg}}$$

**10-69 EES** Problem 10-68 is reconsidered. The problem is to be solved by the diagram window data entry feature of EES by including the effects of the turbine and pump efficiencies. Also, the  $T$ - $s$  diagram is to be plotted.

**Analysis** The problem is solved using EES, and the solution is given below.

```

**10-70** A single-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The power output from the turbine, the thermal efficiency of the plant, the exergy of the geothermal liquid at the exit of the flash chamber, and the exergy destructions and exergy efficiencies for the flash chamber, the turbine, and the entire plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) We use properties of water for geothermal water (Tables A-4, A-5, and A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} \begin{array}{l} h_1 = 990.14 \text{ kJ/kg} \\ s_1 = 2.6100 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} x_2 = 0.1661 \\ s_2 = 2.6841 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\begin{aligned} \dot{m}_3 &= x_2 \dot{m}_1 \\ &= (0.1661)(230 \text{ kg/s}) \\ &= 38.19 \text{ kg/s} \end{aligned}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2748.1 \text{ kJ/kg} \\ s_3 = 6.8207 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.95 \end{array} \right\} \begin{array}{l} h_4 = 2464.3 \text{ kJ/kg} \\ s_4 = 7.7739 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{array} \right\} \begin{array}{l} h_6 = 640.09 \text{ kJ/kg} \\ s_6 = 1.8604 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 38.19 = 191.81 \text{ kg/s}$$

The power output from the turbine is

$$\dot{W}_T = \dot{m}_3 (h_3 - h_4) = (38.19 \text{ kJ/kg})(2748.1 - 2464.3) \text{ kJ/kg} = \mathbf{10,842 \text{ kW}}$$

We use saturated liquid state at the standard temperature for dead state properties

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} \begin{array}{l} h_0 = 104.83 \text{ kJ/kg} \\ s_0 = 0.3672 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\dot{E}_{\text{in}} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{10,842}{203,622} = 0.0532 = \mathbf{5.3\%}$$

(b) The specific exergies at various states are

$$\psi_1 = h_1 - h_0 - T_0 (s_1 - s_0) = (990.14 - 104.83) \text{ kJ/kg} - (298 \text{ K})(2.6100 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 216.53 \text{ kJ/kg}$$

$$\psi_2 = h_2 - h_0 - T_0 (s_2 - s_0) = (990.14 - 104.83) \text{ kJ/kg} - (298 \text{ K})(2.6841 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 194.44 \text{ kJ/kg}$$

$$\psi_3 = h_3 - h_0 - T_0 (s_3 - s_0) = (2748.1 - 104.83) \text{ kJ/kg} - (298 \text{ K})(6.8207 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 719.10 \text{ kJ/kg}$$

$$\psi_4 = h_4 - h_0 - T_0 (s_4 - s_0) = (2464.3 - 104.83) \text{ kJ/kg} - (298 \text{ K})(7.7739 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 151.05 \text{ kJ/kg}$$

$$\psi_6 = h_6 - h_0 - T_0 (s_6 - s_0) = (640.09 - 104.83) \text{ kJ/kg} - (298 \text{ K})(1.8604 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 89.97 \text{ kJ/kg}$$

The exergy of geothermal water at state 6 is

$$\dot{X}_6 = \dot{m}_6 \psi_6 = (191.81 \text{ kg/s})(89.97 \text{ kJ/kg}) = \mathbf{17,257 \text{ kW}}$$

(c) Flash chamber:

$$\dot{X}_{\text{dest, FC}} = \dot{m}_1 (\psi_1 - \psi_2) = (230 \text{ kg/s})(216.53 - 194.44) \text{ kJ/kg} = \mathbf{5080 \text{ kW}}$$

$$\eta_{\text{II, FC}} = \frac{\psi_2}{\psi_1} = \frac{194.44}{216.53} = 0.898 = \mathbf{89.8\%}$$

(d) Turbine:

$$\dot{X}_{\text{dest, T}} = \dot{m}_3 (\psi_3 - \psi_4) - \dot{W}_T = (38.19 \text{ kg/s})(719.10 - 151.05) \text{ kJ/kg} - 10,842 \text{ kW} = \mathbf{10,854 \text{ kW}}$$

$$\eta_{\text{II, T}} = \frac{\dot{W}_T}{\dot{m}_3 (\psi_3 - \psi_4)} = \frac{10,842 \text{ kW}}{(38.19 \text{ kg/s})(719.10 - 151.05) \text{ kJ/kg}} = 0.500 = \mathbf{50.0\%}$$

(e) Plant:

$$\dot{X}_{\text{in, Plant}} = \dot{m}_1 \psi_1 = (230 \text{ kg/s})(216.53 \text{ kJ/kg}) = 49,802 \text{ kW}$$

$$\dot{X}_{\text{dest, Plant}} = \dot{X}_{\text{in, Plant}} - \dot{W}_T = 49,802 - 10,842 = \mathbf{38,960 \text{ kW}}$$

$$\eta_{\text{II, Plant}} = \frac{\dot{W}_T}{\dot{X}_{\text{in, Plant}}} = \frac{10,842 \text{ kW}}{49,802 \text{ kW}} = 0.2177 = \mathbf{21.8\%}$$

## **Cogeneration**

**10-71C** The utilization factor of a cogeneration plant is the ratio of the energy utilized for a useful purpose to the total energy supplied. It could be unity for a plant that does not produce any power.

**10-72C** No. A cogeneration plant may involve throttling, friction, and heat transfer through a finite temperature difference, and still have a utilization factor of unity.

**10-73C** Yes, if the cycle involves no irreversibilities such as throttling, friction, and heat transfer through a finite temperature difference.

**10-74C** Cogeneration is the production of more than one useful form of energy from the same energy source. Regeneration is the transfer of heat from the working fluid at some stage to the working fluid at some other stage.

**10-75** A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The net power produced and the utilization factor of the plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = v_1 (P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(600 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.60 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 0.60 = 192.41 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{steady}} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

$$\text{or, } h_4 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(22.50)(192.41) + (7.50)(670.38)}{30} = 311.90 \text{ kJ/kg}$$

$$v_4 \approx v_f @ h_f = 311.90 \text{ kJ/kg} = 0.001026 \text{ m}^3/\text{kg}$$

$$w_{pII, \text{in}} = v_4 (P_5 - P_4)$$

$$= (0.001026 \text{ m}^3/\text{kg})(7000 - 600 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 6.57 \text{ kJ/kg}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 311.90 + 6.57 = 318.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 7 \text{ MPa} \\ T_6 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_6 = 3411.4 \text{ kJ/kg} \\ s_6 = 6.8000 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_7 = 0.6 \text{ MPa} \\ s_7 = s_6 \end{array} \right\} h_7 = 2774.6 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 10 \text{ kPa} \\ s_8 = s_6 \end{array} \right\} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{6.8000 - 0.6492}{7.4996} = 0.8201$$

$$h_8 = h_f + x_8 h_{fg} = 191.81 + (0.8201)(2392.1) = 2153.6 \text{ kJ/kg}$$

Then,

$$\dot{W}_{T, \text{out}} = \dot{m}_6 (h_6 - h_7) + \dot{m}_8 (h_7 - h_8)$$

$$= (30 \text{ kg/s})(3411.4 - 2774.6) \text{ kJ/kg} + (22.5 \text{ kg/s})(2774.6 - 2153.6) \text{ kJ/kg} = 33,077 \text{ kW}$$

$$\dot{W}_{p, \text{in}} = \dot{m}_1 w_{pI, \text{in}} + \dot{m}_4 w_{pII, \text{in}} = (22.5 \text{ kg/s})(0.60 \text{ kJ/kg}) + (30 \text{ kg/s})(6.57 \text{ kJ/kg}) = 210.6 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{T, \text{out}} - \dot{W}_{p, \text{in}} = 33,077 - 210.6 = \mathbf{32,866 \text{ kW}}$$

$$\text{Also, } \dot{Q}_{\text{process}} = \dot{m}_7 (h_7 - h_3) = (7.5 \text{ kg/s})(2774.6 - 670.38) \text{ kJ/kg} = 15,782 \text{ kW}$$

$$\dot{Q}_{\text{in}} = \dot{m}_5 (h_6 - h_5) = (30 \text{ kg/s})(3411.4 - 318.47) = 92,788 \text{ kW}$$

$$\text{and } \varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{32,866 + 15,782}{92,788} = \mathbf{52.4\%}$$

**10-76E** A large food-processing plant requires steam at a relatively high pressure, which is extracted from the turbine of a cogeneration plant. The rate of heat transfer to the boiler and the power output of the cogeneration plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis**

(a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 2 \text{ psia} = 94.02 \text{ Btu/lbm}$$

$$\nu_1 = \nu_f @ 2 \text{ psia} = 0.01623 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= \frac{1}{0.86} (0.01623 \text{ ft}^3/\text{lbm}) (80 - 2) \text{ psia} \\ &\quad \times \left( \frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.27 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 94.02 + 0.27 = 94.29 \text{ Btu/lbm}$$

$$h_3 = h_f @ 80 \text{ psia} = 282.13 \text{ Btu/lbm}$$

Mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

or,

$$h_4 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(3)(94.29) + (2)(282.13)}{5} = 169.43 \text{ Btu/lbm}$$

$$\nu_4 \cong \nu_f @ h_f = 169.43 \text{ Btu/lbm} = 0.01664 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_4 (P_5 - P_4) / \eta_p \\ &= (0.01664 \text{ ft}^3/\text{lbm}) (1000 - 80 \text{ psia}) \left( \frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) / (0.86) \\ &= 3.29 \text{ Btu/lbm} \end{aligned}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 169.43 + 3.29 = 172.72 \text{ Btu/lbm}$$

$$\left. \begin{aligned} P_6 &= 1000 \text{ psia} \\ T_6 &= 1000^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_6 &= 1506.2 \text{ Btu/lbm} \\ s_6 &= 1.6535 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\left. \begin{aligned} P_{7s} &= 80 \text{ psia} \\ s_{7s} &= s_6 \end{aligned} \right\} h_{7s} = 1209.0 \text{ Btu/lbm}$$

$$\left. \begin{aligned} P_{8s} &= 2 \text{ psia} \\ s_{8s} &= s_6 \end{aligned} \right\} \begin{aligned} x_{8s} &= \frac{s_{8s} - s_f}{s_{fg}} = \frac{1.6535 - 0.17499}{1.74444} = 0.8475 \\ h_{8s} &= h_f + x_{8s} h_{fg} = 94.02 + (0.8475)(1021.7) = 959.98 \text{ Btu/lbm} \end{aligned}$$

$$\text{Then, } \dot{Q}_{\text{in}} = \dot{m}_5 (h_6 - h_5) = (5 \text{ lbm/s})(1506.2 - 172.72) \text{ Btu/lbm} = \mathbf{6667 \text{ Btu/s}}$$

$$\begin{aligned} (b) \quad \dot{W}_{T, \text{out}} &= \eta_T \dot{W}_{T, s} = \eta_T [\dot{m}_6 (h_6 - h_{7s}) + \dot{m}_8 (h_{7s} - h_{8s})] \\ &= (0.86) [(5 \text{ lbm/s})(1506.2 - 1209.0) \text{ Btu/lbm} + (3 \text{ lbm/s})(1209.0 - 959.98) \text{ Btu/lbm}] \\ &= 1921 \text{ Btu/s} = \mathbf{2026 \text{ kW}} \end{aligned}$$

**10-77** A cogeneration plant has two modes of operation. In the first mode, all the steam leaving the turbine at a relatively high pressure is routed to the process heater. In the second mode, 60 percent of the steam is routed to the process heater and remaining is expanded to the condenser pressure. The power produced and the rate at which process heat is supplied in the first mode, and the power produced and the rate of process heat supplied in the second mode are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(10,000 - 20 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.15 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 251.42 + 10.15 = 261.57 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg}$$

$$\nu_3 = \nu_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_3 (P_4 - P_3) \\ &= (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.38 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 640.09 + 10.38 = 650.47 \text{ kJ/kg}$$

Mixing chamber:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_5 h_5 = \dot{m}_2 h_2 + \dot{m}_4 h_4 \end{aligned}$$

$$\text{or, } h_5 = \frac{\dot{m}_2 h_2 + \dot{m}_4 h_4}{\dot{m}_5} = \frac{(2)(261.57) + (3)(650.47)}{5} = 494.91 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ MPa} \\ T_6 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_6 = 3242.4 \text{ kJ/kg} \\ s_6 = 6.4219 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_7 = 0.5 \text{ MPa} \\ s_7 = s_6 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.4219 - 1.8604}{4.9603} = 0.9196 \\ h_7 = h_f + x_7 h_{fg} = 640.09 + (0.9196)(2108.0) = 2578.6 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_8 = 20 \text{ kPa} \\ s_8 = s_6 \end{array} \right\} \begin{array}{l} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{6.4219 - 0.8320}{7.0752} = 0.7901 \\ h_8 = h_f + x_8 h_{fg} = 251.42 + (0.7901)(2357.5) = 2114.0 \text{ kJ/kg} \end{array}$$

When the entire steam is routed to the process heater,

$$\dot{W}_{\text{T, out}} = \dot{m}_6 (h_6 - h_7) = (5 \text{ kg/s})(3242.4 - 2578.6) \text{ kJ/kg} = \mathbf{3319 \text{ kW}}$$

$$\dot{Q}_{\text{process}} = \dot{m}_7 (h_7 - h_3) = (5 \text{ kg/s})(2578.6 - 640.09) \text{ kJ/kg} = \mathbf{9693 \text{ kW}}$$

(b) When only 60% of the steam is routed to the process heater,

$$\begin{aligned} \dot{W}_{\text{T, out}} &= \dot{m}_6 (h_6 - h_7) + \dot{m}_8 (h_7 - h_8) \\ &= (5 \text{ kg/s})(3242.4 - 2578.6) \text{ kJ/kg} + (2 \text{ kg/s})(2578.6 - 2114.0) \text{ kJ/kg} = \mathbf{4248 \text{ kW}} \end{aligned}$$

$$\dot{Q}_{\text{process}} = \dot{m}_7 (h_7 - h_3) = (3 \text{ kg/s})(2578.6 - 640.09) \text{ kJ/kg} = \mathbf{5816 \text{ kW}}$$

**10-78** A cogeneration plant modified with regeneration is to generate power and process heat. The mass flow rate of steam through the boiler for a net power output of 15 MW is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

### Analysis

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= \nu_1 (P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg}) (400 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.39 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 191.81 + 0.39 = 192.20 \text{ kJ/kg}$$

$$h_3 = h_4 = h_9 = h_f @ 0.4 \text{ MPa} = 604.66 \text{ kJ/kg}$$

$$\nu_4 = \nu_f @ 0.4 \text{ MPa} = 0.001084 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII,in} &= \nu_4 (P_5 - P_4) \\ &= (0.001084 \text{ m}^3/\text{kg}) (6000 - 400 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.07 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII,in} = 604.66 + 6.07 = 610.73 \text{ kJ/kg}$$

$$\begin{aligned} P_6 &= 6 \text{ MPa} \quad \left. \begin{aligned} h_6 &= 3302.9 \text{ kJ/kg} \\ T_6 &= 450^\circ\text{C} \end{aligned} \right\} s_6 = 6.7219 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} P_7 &= 0.4 \text{ MPa} \quad \left. \begin{aligned} x_7 &= \frac{s_7 - s_f}{s_{fg}} = \frac{6.7219 - 1.7765}{5.1191} = 0.9661 \\ s_7 &= s_6 \end{aligned} \right\} h_7 = h_f + x_7 h_{fg} = 604.66 + (0.9661)(2133.4) = 2665.7 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} P_8 &= 10 \text{ kPa} \quad \left. \begin{aligned} x_8 &= \frac{s_8 - s_f}{s_{fg}} = \frac{6.7219 - 0.6492}{7.4996} = 0.8097 \\ s_8 &= s_6 \end{aligned} \right\} h_8 = h_f + x_8 h_{fg} = 191.81 + (0.8097)(2392.1) = 2128.7 \text{ kJ/kg} \end{aligned}$$

Then, per kg of steam flowing through the boiler, we have

$$\begin{aligned} w_{T,out} &= (h_6 - h_7) + 0.4(h_7 - h_8) \\ &= (3302.9 - 2665.7) \text{ kJ/kg} + (0.4)(2665.7 - 2128.7) \text{ kJ/kg} \\ &= 852.0 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} w_{p,in} &= 0.4 w_{pI,in} + w_{pII,in} \\ &= (0.4)(0.39 \text{ kJ/kg}) + (6.07 \text{ kJ/kg}) \\ &= 6.23 \text{ kJ/kg} \end{aligned}$$

$$w_{net} = w_{T,out} - w_{p,in} = 852.0 - 6.23 = 845.8 \text{ kJ/kg}$$

Thus,

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{15,000 \text{ kJ/s}}{845.8 \text{ kJ/kg}} = \mathbf{17.73 \text{ kg/s}}$$

**10-79 EES** Problem 10-78 is reconsidered. The effect of the extraction pressure for removing steam from the turbine to be used for the process heater and open feedwater heater on the required mass flow rate is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

#### "Input Data"

```
y = 0.6 "fraction of steam extracted from turbine for feedwater heater and process heater"
P[6] = 6000 [kPa]

**10-80E** A cogeneration plant is to generate power while meeting the process steam requirements for a certain industrial application. The net power produced, the rate of process heat supply, and the utilization factor of this plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis**

(a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 \cong h_f @ 240^\circ\text{F} = 208.49 \text{ Btu/lbm}$$

$$h_2 \cong h_1$$

$$\left. \begin{array}{l} P_3 = 600 \text{ psia} \\ T_3 = 800^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1408.0 \text{ Btu/lbm} \\ s_3 = s_5 = s_7 = 1.6348 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$h_3 = h_4 = h_5 = h_6$$

$$\left. \begin{array}{l} P_7 = 120 \text{ psia} \\ s_7 = s_3 \end{array} \right\} h_7 = 1229.5 \text{ Btu/lbm}$$

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m}_5 (h_5 - h_7) \\ &= (12 \text{ lbm/s})(1408.0 - 1229.5) \text{ Btu/lbm} \\ &= 2142 \text{ Btu/s} = \mathbf{2260 \text{ kW}} \end{aligned}$$

$$\begin{aligned} (b) \quad \dot{Q}_{\text{process}} &= \sum \dot{m}_i h_i - \sum \dot{m}_e h_e \\ &= \dot{m}_6 h_6 + \dot{m}_7 h_7 - \dot{m}_1 h_1 - \\ &= (6)(1408.0) + (12)(1229.5) - (18)(208.49) \\ &= \mathbf{19,450 \text{ Btu/s}} \end{aligned}$$

$$\begin{aligned} \dot{Q}_{\text{process}} &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i = \dot{m}_1 h_1 - \dot{m}_6 h_6 - \dot{m}_7 h_7 \\ &= (18)(208.49) - (6)(1408.0) - (12)(1229.5) \\ &= \mathbf{-19,450 \text{ Btu/s}} \end{aligned}$$

(c)  $\varepsilon_u = 1$  since all the energy is utilized.

**10-81** A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The mass flow rate of steam that must be supplied by the boiler, the net power produced, and the utilization factor of the plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(600 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.596 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 0.596 = 192.40 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{m}_3 h_3 + \dot{m}_2 h_2 = \dot{m}_4 h_4$$

$$(0.25)(670.38 \text{ kJ/kg}) + (0.75)(192.40 \text{ kJ/kg}) = (1)h_4 \longrightarrow h_4 = 311.90 \text{ kJ/kg}$$

$$\nu_4 \cong \nu_f @ h_f = 311.90 \text{ kJ/kg} = 0.001026 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_4 (P_5 - P_4) \\ &= (0.001026 \text{ m}^3/\text{kg})(7000 - 600 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.563 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 311.90 + 6.563 = 318.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 7 \text{ MPa} \\ T_6 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_6 = 3411.4 \text{ kJ/kg} \\ s_6 = 6.8000 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_7 = 0.6 \text{ MPa} \\ s_7 = s_6 \end{array} \right\} h_7 = 2773.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 10 \text{ kPa} \\ s_8 = s_6 \end{array} \right\} h_8 = 2153.6 \text{ kJ/kg}$$

$$\begin{aligned} \dot{Q}_{\text{process}} &= \dot{m}_7(h_7 - h_3) \\ 8600 \text{ kJ/s} &= \dot{m}_7(2773.9 - 670.38) \text{ kJ/kg} \\ \dot{m}_7 &= 4.088 \text{ kg/s} \end{aligned}$$

This is one-fourth of the mass flowing through the boiler. Thus, the mass flow rate of steam that must be supplied by the boiler becomes

$$\dot{m}_6 = 4\dot{m}_7 = 4(4.088 \text{ kg/s}) = \mathbf{16.35 \text{ kg/s}}$$

(b) Cycle analysis:

$$\begin{aligned} \dot{W}_{\text{T,out}} &= \dot{m}_7(h_6 - h_7) + \dot{m}_8(h_6 - h_8) \\ &= (4.088 \text{ kg/s})(3411.4 - 2773.9) \text{ kJ/kg} + (16.35 - 4.088 \text{ kg/s})(3411.4 - 2153.6) \text{ kJ/kg} \\ &= 18,033 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{W}_{\text{p,in}} &= \dot{m}_1 w_{\text{pI,in}} + \dot{m}_4 w_{\text{pII,in}} \\ &= (16.35 - 4.088 \text{ kg/s})(0.596 \text{ kJ/kg}) + (16.35 \text{ kg/s})(6.563 \text{ kJ/kg}) = 114.6 \text{ kW} \end{aligned}$$

$$\dot{W}_{\text{net}} = \dot{W}_{\text{T,out}} - \dot{W}_{\text{p,in}} = 18,033 - 115 = \mathbf{17,919 \text{ kW}}$$

(c) Then,

$$\dot{Q}_{\text{in}} = \dot{m}_5(h_6 - h_5) = (16.35 \text{ kg/s})(3411.4 - 318.46) = 50,581 \text{ kW}$$

and

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{17,919 + 8600}{50,581} = 0.524 = \mathbf{52.4\%}$$

## Combined Gas-Vapor Power Cycles

**10-82C** The energy source of the steam is the waste energy of the exhausted combustion gases.

**10-83C** Because the combined gas-steam cycle takes advantage of the desirable characteristics of the gas cycle at high temperature, and those of steam cycle at low temperature, and combines them. The result is a cycle that is more efficient than either cycle executed operated alone.

**10-84 [Also solved by EES on enclosed CD]** A 450-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is an ideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) The analysis of gas cycle yields (Table A-17)

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg}$$

$$P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (14)(1.386) = 19.40 \longrightarrow h_9 = 635.5 \text{ kJ/kg}$$

$$T_{10} = 1400 \text{ K} \longrightarrow h_{10} = 1515.42 \text{ kJ/kg}$$

$$P_{r_{10}} = 450.5$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left(\frac{1}{14}\right)(450.5) = 32.18 \longrightarrow h_{11} = 735.8 \text{ kJ/kg}$$

$$T_{12} = 460 \text{ K} \longrightarrow h_{12} = 462.02 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{pI,in} = v_1(P_2 - P_1)$$

$$= (0.001017 \text{ m}^3/\text{kg})(600 - 20 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.59 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,in} = 251.42 + 0.59 = 252.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

$$v_3 = v_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

$$w_{pII,in} = v_3(P_4 - P_3)$$

$$= (0.001101 \text{ m}^3/\text{kg})(8,000 - 600 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 8.15 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII,in} = 670.38 + 8.15 = 678.53 \text{ kJ/kg}$$

$$P_5 = 8 \text{ MPa} \left\{ h_5 = 3139.4 \text{ kJ/kg} \right.$$

$$T_5 = 400^\circ\text{C} \left\{ s_5 = 6.3658 \text{ kJ/kg} \cdot \text{K} \right.$$

$$P_6 = 0.6 \text{ MPa} \left\{ x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.3658 - 1.9308}{4.8285} = 0.9185 \right.$$

$$s_6 = s_5 \left\{ h_6 = h_f + x_6 h_{fg} = 670.38 + (0.9185)(2085.8) = 2586.1 \text{ kJ/kg} \right.$$

$$P_7 = 20 \text{ kPa} \left\{ x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.3658 - 0.8320}{7.0752} = 0.7821 \right.$$

$$s_7 = s_5 \left\{ h_7 = h_f + x_7 h_{fg} = 251.42 + (0.7821)(2357.5) = 2095.2 \text{ kJ/kg} \right.$$

Noting that  $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$  for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned}
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \overset{\varphi 0 \text{ (steady)}}{=} 0 \\
\dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\
\sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_5 - h_4) = \dot{m}_{\text{air}} (h_{11} - h_{12}) \\
\frac{\dot{m}_{\text{air}}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3139.4 - 678.53}{735.80 - 462.02} = \mathbf{8.99 \text{ kg air / kg steam}}
\end{aligned}$$

(b) Noting that  $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$  for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned}
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \overset{\varphi 0 \text{ (steady)}}{=} 0 \\
\dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\
\sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = (1) h_3
\end{aligned}$$

Thus,

$$\begin{aligned}
y &= \frac{h_3 - h_2}{h_6 - h_2} = \frac{670.38 - 252.01}{2586.1 - 252.01} = 0.1792 \quad (\text{the fraction of steam extracted}) \\
w_T &= h_5 - h_6 + (1 - y)(h_6 - h_7) \\
&= 3139.4 - 2586.1 + (1 - 0.1792)(2586.1 - 2095.2) = 956.23 \text{ kJ/kg} \\
w_{\text{net, steam}} &= w_T - w_{p, \text{in}} = w_T - (1 - y)w_{p, I} - w_{p, II} \\
&= 956.23 - (1 - 0.1792)(0.59) - 8.15 = 948.56 \text{ kJ/kg} \\
w_{\text{net, gas}} &= w_T - w_{C, \text{in}} = (h_{10} - h_{11}) - (h_9 - h_8) \\
&= 1515.42 - 735.8 - (635.5 - 300.19) = 444.3 \text{ kJ/kg}
\end{aligned}$$

The net work output per unit mass of gas is

$$w_{\text{net}} = w_{\text{net, gas}} + \frac{1}{8.99} w_{\text{net, steam}} = 444.3 + \frac{1}{8.99}(948.56) = 549.8 \text{ kJ/kg}$$

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{450,000 \text{ kJ/s}}{549.7 \text{ kJ/kg}} = 818.7 \text{ kg/s}$$

and

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_{10} - h_9) = (818.7 \text{ kg/s})(1515.42 - 635.5) \text{ kJ/kg} = \mathbf{720,215 \text{ kW}}$$

$$(c) \quad \eta_{th} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{450,000 \text{ kW}}{720,215 \text{ kW}} = \mathbf{62.5\%}$$

**10-85 EES** Problem 10-84 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**"Input data"**

**10-86** A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The mass flow rate of air for a specified power output is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left( \frac{P_6}{P_5} \right)^{(k-1)/k} = (293 \text{ K})(8)^{0.4/1.4} = 530.8 \text{ K}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\begin{aligned} \longrightarrow T_6 &= T_5 + \frac{T_{6s} - T_5}{\eta_C} \\ &= 293 + \frac{530.8 - 293}{0.85} = 572.8 \text{ K} \end{aligned}$$

$$T_{8s} = T_7 \left( \frac{P_8}{P_7} \right)^{(k-1)/k} = (1373 \text{ K}) \left( \frac{1}{8} \right)^{0.4/1.4} = 758.0 \text{ K}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_{8s}}{h_7 - h_8} = \frac{c_p(T_7 - T_{8s})}{c_p(T_7 - T_8)} \longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 1373 - (0.90)(1373 - 758.0) \\ &= 819.5 \text{ K} \end{aligned}$$

$$T_9 = T_{\text{sat @ } 6000 \text{ kPa}} = 275.6^\circ\text{C} = 548.6 \text{ K}$$

Fixing the states around the bottom steam cycle yields (Tables A-4, A-5, A-6):

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(6000 - 20) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.08 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 6.08 = 257.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 6000 \text{ kPa} \\ T_3 = 320^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 2953.6 \text{ kJ/kg} \\ s_3 = 6.1871 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 20 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 2035.8 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 2953.6 - (0.90)(2953.6 - 2035.8) \\ &= 2127.6 \text{ kJ/kg} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned}
 w_{\text{net, gas cycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\
 &= c_p (T_7 - T_8) - c_p (T_6 - T_5) \\
 &= (1.005 \text{ kJ/kg} \cdot \text{K})(1373 - 819.5 - 572.7 + 293)\text{K} \\
 &= 275.2 \text{ kJ/kg}
 \end{aligned}$$

$$\begin{aligned}
 w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\
 &= (h_3 - h_4) - w_{P,\text{in}} \\
 &= (2953.6 - 2127.6) - 6.08 \\
 &= 819.9 \text{ kJ/kg}
 \end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(1.005)(819.5 - 548.6)}{2953.6 - 257.5} \dot{m}_a = 0.1010 \dot{m}_a$$

That is, 1 kg of exhaust gases can heat only 0.1010 kg of water. Then, the mass flow rate of air is

$$\dot{m}_a = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{100,000 \text{ kJ/s}}{(1 \times 275.2 + 0.1010 \times 819.9) \text{ kJ/kg air}} = \mathbf{279.3 \text{ kg/s}}$$

**10-87** A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The mass flow rate of air for a specified power output is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** With an ideal regenerator, the temperature of the air at the compressor exit will be heated to the temperature at the turbine exit. Representing this state by “6a”

$$T_{6a} = T_8 = 819.5 \text{ K}$$

The rate of heat addition in the cycle is

$$\begin{aligned}\dot{Q}_{\text{in}} &= \dot{m}_a c_p (T_7 - T_{6a}) \\ &= (279.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot^\circ\text{C})(1373 - 819.5) \text{ K} \\ &= 155,370 \text{ kW}\end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{100,000 \text{ kW}}{155,370 \text{ kW}} = \mathbf{0.6436}$$

Without the regenerator, the rate of heat addition and the thermal efficiency are

$$\dot{Q}_{\text{in}} = \dot{m}_a c_p (T_7 - T_6) = (279.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot^\circ\text{C})(1373 - 572.7) \text{ K} = 224,640 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{100,000 \text{ kW}}{224,640 \text{ kW}} = \mathbf{0.4452}$$

The change in the thermal efficiency due to using the ideal regenerator is

$$\Delta\eta_{\text{th}} = 0.6436 - 0.4452 = \mathbf{0.1984}$$

**10-88** The component of the combined cycle with the largest exergy destruction of the component of the combined cycle in Prob. 10-86 is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Problem 10-86,

$$T_{\text{source, gas cycle}} = 1373 \text{ K}$$

$$T_{\text{source, steam cycle}} = T_8 = 819.5 \text{ K}$$

$$T_{\text{sink}} = 293 \text{ K}$$

$$s_1 = s_2 = s_f @ 20 \text{ kPa} = 0.8320 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = 6.1871 \text{ kJ/kg} \cdot \text{K}$$

$$s_4 = 6.4627 \text{ kJ/kg} \cdot \text{K}$$

$$q_{\text{in},67} = c_p (T_7 - T_6) = 804.3 \text{ kJ/kg}$$

$$q_{\text{in},23} = h_3 - h_2 = 2696.1 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 1876.2 \text{ kJ/kg}$$

$$\dot{m}_w = 0.1010 \dot{m}_a = 0.1010(279.3) = 28.21 \text{ kg/s}$$

$$\dot{X}_{\text{destroyed},12} = 0 \quad (\text{isentropic process})$$

$$\dot{X}_{\text{destroyed},34} = \dot{m}_w T_0 (s_4 - s_3) = (28.21 \text{ kg/s})(293 \text{ K})(6.4627 - 6.1871) = 2278 \text{ kW}$$

$$\begin{aligned} \dot{X}_{\text{destroyed},41} &= \dot{m}_w T_0 \left( s_1 - s_4 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) \\ &= (28.21 \text{ kg/s})(293 \text{ K}) \left( 0.8320 - 6.1871 + \frac{1876.2 \text{ kJ/kg}}{293 \text{ K}} \right) = 8665 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{X}_{\text{destroyed,heat exchanger}} &= \dot{m}_a T_0 \Delta s_{89} + \dot{m}_w T_0 \Delta s_{23} = \dot{m}_a T_0 \left( c_p \ln \frac{T_9}{T_8} \right) + \dot{m}_w T_0 (s_3 - s_2) \\ &= (279.3)(293) \left[ (1.005) \ln \frac{548.6}{819.5} \right] + (28.21)(293)(6.1871 - 0.8320) \\ &= 11260 \text{ kW} \end{aligned}$$

$$\dot{X}_{\text{destroyed},56} = \dot{m}_a T_0 \left( c_p \ln \frac{T_6}{T_5} - R \ln \frac{P_6}{P_5} \right) = (279.3)(293) \left[ (1.005) \ln \frac{572.7}{293} - (0.287) \ln(8) \right] = 6280 \text{ kW}$$

$$\dot{X}_{\text{destroyed},67} = \dot{m}_a T_0 \left( c_p \ln \frac{T_7}{T_6} - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (279.3)(293) \left[ (1.005) \ln \frac{1373}{572.7} - \frac{804.3}{1373} \right] = \mathbf{23,970 \text{ kW}}$$

$$\dot{X}_{\text{destroyed},78} = \dot{m}_a T_0 \left( c_p \ln \frac{T_8}{T_7} - R \ln \frac{P_8}{P_7} \right) = (279.3)(293) \left[ (1.005) \ln \frac{819.5}{1373} - (0.287) \ln \left( \frac{1}{8} \right) \right] = 6396 \text{ kW}$$

The largest exergy destruction occurs during the heat addition process in the combustor of the gas cycle.

**10-89** A 450-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) Using the properties of air from Table A-17, the analysis of gas cycle yields

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg}$$

$$P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (14)(1.386) = 19.40 \longrightarrow h_{9s} = 635.5 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{9s} - h_8}{h_9 - h_8} \longrightarrow h_9 = h_8 + (h_{9s} - h_8) / \eta_C$$

$$= 300.19 + (635.5 - 300.19) / (0.82)$$

$$= 709.1 \text{ kJ/kg}$$

$$T_{10} = 1400 \text{ K} \longrightarrow h_{10} = 1515.42 \text{ kJ/kg}$$

$$P_{r_{10}} = 450.5$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left( \frac{1}{14} \right) (450.5) = 32.18 \longrightarrow h_{11s} = 735.8 \text{ kJ/kg}$$

$$\eta_T = \frac{h_{10} - h_{11}}{h_{10} - h_{11s}} \longrightarrow h_{11} = h_{10} - \eta_T (h_{10} - h_{11s})$$

$$= 1515.42 - (0.86)(1515.42 - 735.8)$$

$$= 844.95 \text{ kJ/kg}$$

$$T_{12} = 460 \text{ K} \longrightarrow h_{12} = 462.02 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = \nu_1 (P_2 - P_1)$$

$$= (0.001017 \text{ m}^3/\text{kg})(600 - 20 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.59 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 251.42 + 0.59 = 252.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

$$\nu_3 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

$$w_{pII, \text{in}} = \nu_3 (P_4 - P_3)$$

$$= (0.001101 \text{ m}^3/\text{kg})(8,000 - 600 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 8.15 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 670.38 + 8.15 = 678.52 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 8 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3139.4 \text{ kJ/kg} \\ s_5 = 6.3658 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\begin{aligned}
 P_6 = 0.6 \text{ MPa} \quad \left\{ \begin{aligned} x_{6s} &= \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.3658 - 1.9308}{4.8285} = 0.9184 \\ h_{6s} &= h_f + x_{6s} h_{fg} = 670.38 + (0.9184)(2085.8) = 2585.9 \text{ kJ/kg} \end{aligned} \right. \\
 s_{6s} = s_5 \\
 \eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) = 3139.4 - (0.86)(3139.4 - 2585.9) = 2663.3 \text{ kJ/kg} \\
 P_7 = 20 \text{ kPa} \quad \left\{ \begin{aligned} x_{7s} &= \frac{s_7 - s_f}{s_{fg}} = \frac{6.3658 - 0.8320}{7.0752} = 0.7820 \\ h_{7s} &= h_f + x_{7s} h_{fg} = 251.42 + (0.7820)(2357.5) = 2095.1 \text{ kJ/kg} \end{aligned} \right. \\
 s_7 = s_5 \\
 \eta_T = \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T (h_5 - h_{7s}) = 3139.4 - (0.86)(3139.4 - 2095.1) = 2241.3 \text{ kJ/kg}
 \end{aligned}$$

Noting that  $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$  for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned}
 \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \quad \phi^0(\text{steady}) = 0 \\
 \dot{E}_{in} &= \dot{E}_{out} \\
 \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_5 - h_4) = \dot{m}_{air} (h_{11} - h_{12}) \\
 \frac{\dot{m}_{air}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3139.4 - 678.52}{844.95 - 462.02} = \mathbf{6.425 \text{ kg air / kg steam}}
 \end{aligned}$$

(b) Noting that  $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$  for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned}
 \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \quad \phi^0(\text{steady}) = 0 \rightarrow \dot{E}_{in} = \dot{E}_{out} \\
 \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = (1) h_3
 \end{aligned}$$

Thus,

$$\begin{aligned}
 y &= \frac{h_3 - h_2}{h_6 - h_2} = \frac{670.38 - 252.01}{2663.3 - 252.01} = 0.1735 \quad (\text{the fraction of steam extracted}) \\
 w_T &= \eta_T [h_5 - h_6 + (1 - y)(h_6 - h_7)] \\
 &= (0.86)[3139.4 - 2663.3 + (1 - 0.1735)(2663.3 - 2241.3)] = 824.5 \text{ kJ/kg} \\
 w_{\text{net, steam}} &= w_T - w_{p, in} = w_T - (1 - y)w_{p, I} - w_{p, II} \\
 &= 824.5 - (1 - 0.1735)(0.59) - 8.15 = 815.9 \text{ kJ/kg} \\
 w_{\text{net, gas}} &= w_T - w_{C, in} = (h_{10} - h_{11}) - (h_9 - h_8) \\
 &= 1515.42 - 844.95 - (709.1 - 300.19) = 261.56 \text{ kJ/kg}
 \end{aligned}$$

The net work output per unit mass of gas is

$$\begin{aligned}
 w_{\text{net}} &= w_{\text{net, gas}} + \frac{1}{6.425} w_{\text{net, steam}} = 261.56 + \frac{1}{6.425} (815.9) = 388.55 \text{ kJ/kg} \\
 \dot{m}_{air} &= \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{450,000 \text{ kJ/s}}{388.55 \text{ kJ/kg}} = 1158.2 \text{ kg/s}
 \end{aligned}$$

and  $\dot{Q}_{in} = \dot{m}_{air} (h_{10} - h_9) = (1158.2 \text{ kg/s})(1515.42 - 709.1) \text{ kJ/kg} = \mathbf{933,850 \text{ kW}}$

$$(c) \quad \eta_{th} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{in}} = \frac{450,000 \text{ kW}}{933,850 \text{ kW}} = \mathbf{48.2\%}$$

**10-90 EES** Problem 10-89 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**Cycle Thermal Efficiency vs Gas Cycle Pressure Ratio**

**$\dot{W}_{dot,gas} / \dot{W}_{dot,steam}$  vs Gas Pressure Ratio**

**Ratio of Gas Flow Rate to Steam Flow Rate vs Gas Pressure Ratio**

**10-91** A combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal reheat Rankine cycle. The moisture percentage at the exit of the low-pressure turbine, the steam temperature at the inlet of the high-pressure turbine, and the thermal efficiency of the combined cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) We obtain the air properties from EES. The analysis of gas cycle is as follows

$$T_7 = 15^\circ\text{C} \longrightarrow h_7 = 288.50 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = 15^\circ\text{C} \\ P_7 = 100 \text{ kPa} \end{array} \right\} s_7 = 5.6648 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 700 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_{8s} = 503.47 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{8s} - h_7}{h_8 - h_7} \longrightarrow h_8 = h_7 + (h_{8s} - h_7) / \eta_C = 290.16 + (503.47 - 290.16) / (0.80) = 557.21 \text{ kJ/kg}$$

$$T_9 = 950^\circ\text{C} \longrightarrow h_9 = 1304.8 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_9 = 950^\circ\text{C} \\ P_9 = 700 \text{ kPa} \end{array} \right\} s_9 = 6.6456 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{10} = 100 \text{ kPa} \\ s_{10} = s_9 \end{array} \right\} h_{10s} = 763.79 \text{ kJ/kg}$$

$$\eta_T = \frac{h_9 - h_{10}}{h_9 - h_{10s}} \longrightarrow h_{10} = h_9 - \eta_T (h_9 - h_{10s}) = 1304.8 - (0.80)(1304.8 - 763.79) = 871.98 \text{ kJ/kg}$$

$$T_{11} = 200^\circ\text{C} \longrightarrow h_{11} = 475.62 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6 or from EES),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p1,\text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(6000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.80 \\ &= 7.56 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p1,\text{in}} = 191.81 + 7.56 = 199.37 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 1 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3264.5 \text{ kJ/kg} \\ s_5 = 7.4670 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ s_{6s} = s_5 \end{array} \right\} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.4670 - 0.6492}{7.4996} = 0.9091$$

$$h_{6s} = h_f + x_{6s} h_{fg} = 191.81 + (0.9091)(2392.1) = 2366.4 \text{ kJ/kg}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s})$$

$$= 3264.5 - (0.80)(3264.5 - 2366.4)$$

$$= 2546.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ h_6 = 2546.5 \text{ kJ/kg} \end{array} \right\} x_6 = 0.9842$$

$$\text{Moisture Percentage} = 1 - x_6 = 1 - 0.9842 = 0.0158 = \mathbf{1.6\%}$$

(b) Noting that  $\dot{Q} \cong \dot{W} \cong \Delta \text{ke} \cong \Delta \text{pe} \cong 0$  for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_s (h_3 - h_2) + \dot{m}_s (h_5 - h_4) = \dot{m}_{\text{air}} (h_{10} - h_{11})$$

$$(1.15)[(3346.5 - 199.37) + (3264.5 - h_4)] = (10)(871.98 - 475.62) \longrightarrow h_4 = 2965.0 \text{ kJ/kg}$$

Also,

$$\left. \begin{array}{l} P_3 = 6 \text{ MPa} \\ T_3 = ? \end{array} \right\} \begin{array}{l} h_3 = \\ s_3 = \end{array} \quad \left. \begin{array}{l} P_4 = 1 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} h_{4s} =$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

The temperature at the inlet of the high-pressure turbine may be obtained by a trial-error approach or using EES from the above relations. The answer is  $T_3 = \mathbf{468.0^\circ\text{C}}$ . Then, the enthalpy at state 3 becomes:  $h_3 = 3346.5 \text{ kJ/kg}$

$$(c) \quad \dot{W}_{\text{T,gas}} = \dot{m}_{\text{air}} (h_9 - h_{10}) = (10 \text{ kg/s})(1304.8 - 871.98) \text{ kJ/kg} = 4328 \text{ kW}$$

$$\dot{W}_{\text{C,gas}} = \dot{m}_{\text{air}} (h_8 - h_7) = (10 \text{ kg/s})(557.21 - 288.50) \text{ kJ/kg} = 2687 \text{ kW}$$

$$\dot{W}_{\text{net,gas}} = \dot{W}_{\text{T,gas}} - \dot{W}_{\text{C,gas}} = 4328 - 2687 = 1641 \text{ kW}$$

$$\dot{W}_{\text{T,steam}} = \dot{m}_s (h_3 - h_4 + h_5 - h_6) = (1.15 \text{ kg/s})(3346.5 - 2965.0 + 3264.5 - 2546.0) \text{ kJ/kg} = 1265 \text{ kW}$$

$$\dot{W}_{\text{P,steam}} = \dot{m}_s w_{\text{pump}} = (1.15 \text{ kg/s})(7.564) \text{ kJ/kg} = 8.7 \text{ kW}$$

$$\dot{W}_{\text{net,steam}} = \dot{W}_{\text{T,steam}} - \dot{W}_{\text{P,steam}} = 1265 - 8.7 = 1256 \text{ kW}$$

$$\dot{W}_{\text{net,plant}} = \dot{W}_{\text{net,gas}} + \dot{W}_{\text{net,steam}} = 1641 + 1256 = \mathbf{2897 \text{ kW}}$$

$$(d) \quad \dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_9 - h_8) = (10 \text{ kg/s})(1304.8 - 557.21) \text{ kJ/kg} = 7476 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net,plant}}}{\dot{Q}_{\text{in}}} = \frac{2897 \text{ kW}}{7476 \text{ kW}} = 0.388 = \mathbf{38.8\%}$$

### Special Topic: Binary Vapor Cycles

**10-92C** Binary power cycle is a cycle which is actually a combination of two cycles; one in the high temperature region, and the other in the low temperature region. Its purpose is to increase thermal efficiency.

**10-93C** Consider the heat exchanger of a binary power cycle. The working fluid of the topping cycle (cycle A) enters the heat exchanger at state 1 and leaves at state 2. The working fluid of the bottoming cycle (cycle B) enters at state 3 and leaves at state 4. Neglecting any changes in kinetic and potential energies, and assuming the heat exchanger is well-insulated, the steady-flow energy balance relation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{0 (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ \dot{m}_A h_2 + \dot{m}_B h_4 &= \dot{m}_A h_1 + \dot{m}_B h_3 \text{ or } \dot{m}_A (h_2 - h_1) = \dot{m}_B (h_3 - h_4)\end{aligned}$$

Thus,

$$\frac{\dot{m}_A}{\dot{m}_B} = \frac{h_3 - h_4}{h_2 - h_1}$$

**10-94C** Steam is not an ideal fluid for vapor power cycles because its critical temperature is low, its saturation dome resembles an inverted V, and its condenser pressure is too low.

**10-95C** Because mercury has a high critical temperature, relatively low critical pressure, but a very low condenser pressure. It is also toxic, expensive, and has a low enthalpy of vaporization.

**10-96C** In binary vapor power cycles, both cycles are vapor cycles. In the combined gas-steam power cycle, one of the cycles is a gas cycle.

## Review Problems

**10-97** It is to be demonstrated that the thermal efficiency of a combined gas-steam power plant  $\eta_{cc}$  can be expressed as  $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$  where  $\eta_g = W_g / Q_{in}$  and  $\eta_s = W_s / Q_{g,out}$  are the thermal efficiencies of the gas and steam cycles, respectively, and the efficiency of a combined cycle is to be obtained.

**Analysis** The thermal efficiencies of gas, steam, and combined cycles can be expressed as

$$\begin{aligned}\eta_{cc} &= \frac{W_{total}}{Q_{in}} = 1 - \frac{Q_{out}}{Q_{in}} \\ \eta_g &= \frac{W_g}{Q_{in}} = 1 - \frac{Q_{g,out}}{Q_{in}} \\ \eta_s &= \frac{W_s}{Q_{g,out}} = 1 - \frac{Q_{out}}{Q_{g,out}}\end{aligned}$$

where  $Q_{in}$  is the heat supplied to the gas cycle, where  $Q_{out}$  is the heat rejected by the steam cycle, and where  $Q_{g,out}$  is the heat rejected from the gas cycle and supplied to the steam cycle.

Using the relations above, the expression  $\eta_g + \eta_s - \eta_g \eta_s$  can be expressed as

$$\begin{aligned}\eta_g + \eta_s - \eta_g \eta_s &= \left(1 - \frac{Q_{g,out}}{Q_{in}}\right) + \left(1 - \frac{Q_{out}}{Q_{g,out}}\right) - \left(1 - \frac{Q_{g,out}}{Q_{in}}\right) \left(1 - \frac{Q_{out}}{Q_{g,out}}\right) \\ &= 1 - \frac{Q_{g,out}}{Q_{in}} + 1 - \frac{Q_{out}}{Q_{g,out}} - 1 + \frac{Q_{g,out}}{Q_{in}} + \frac{Q_{out}}{Q_{g,out}} - \frac{Q_{out}}{Q_{in}} \\ &= 1 - \frac{Q_{out}}{Q_{in}} \\ &= \eta_{cc}\end{aligned}$$

Therefore, the proof is complete. Using the relation above, the thermal efficiency of the given combined cycle is determined to be

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = 0.4 + 0.30 - 0.40 \times 0.30 = \mathbf{0.58}$$

**10-98** The thermal efficiency of a combined gas-steam power plant  $\eta_{cc}$  can be expressed in terms of the thermal efficiencies of the gas and the steam turbine cycles as  $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$ . It is to be shown that the value of  $\eta_{cc}$  is greater than either of  $\eta_g$  or  $\eta_s$ .

**Analysis** By factoring out terms, the relation  $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$  can be expressed as

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = \eta_g + \underbrace{\eta_s(1 - \eta_g)}_{\substack{\text{Positive since} \\ \eta_g < 1}} > \eta_g$$

or

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = \eta_s + \underbrace{\eta_g(1 - \eta_s)}_{\substack{\text{Positive since} \\ \eta_s < 1}} > \eta_s$$

Thus we conclude that the combined cycle is more efficient than either of the gas turbine or steam turbine cycles alone.

**10-99** A steam power plant operating on the ideal Rankine cycle with reheating is considered. The reheat pressures of the cycle are to be determined for the cases of single and double reheat.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Single Reheat: From the steam tables (Tables A-4, A-5, and A-6),

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ x_6 = 0.92 \end{array} \right\} \begin{array}{l} h_6 = h_f + x_6 h_{fg} = 191.81 + (0.92)(2392.1) = 2392.5 \text{ kJ/kg} \\ s_6 = s_f + x_6 s_{fg} = 0.6492 + (0.92)(7.4996) = 7.5488 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} T_5 = 600^\circ\text{C} \\ s_5 = s_6 \end{array} \right\} P_5 = 2780 \text{ kPa}$$

(b) Double Reheat :

$$\left. \begin{array}{l} P_3 = 25 \text{ MPa} \\ T_3 = 600^\circ\text{C} \end{array} \right\} s_3 = 6.3637 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_4 = P_x \\ s_4 = s_3 \end{array} \right\} \text{and} \left. \begin{array}{l} P_5 = P_x \\ T_5 = 600^\circ\text{C} \end{array} \right\}$$

Any pressure  $P_x$  selected between the limits of 25 MPa and 2.78 MPa will satisfy the requirements, and can be used for the double reheat pressure.

**10-100E** A geothermal power plant operating on the simple Rankine cycle using an organic fluid as the working fluid is considered. The exit temperature of the geothermal water from the vaporizer, the rate of heat rejection from the working fluid in the condenser, the mass flow rate of geothermal water at the preheater, and the thermal efficiency of the Level I cycle of this plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The exit temperature of geothermal water from the vaporizer is determined from the steady-flow energy balance on the geothermal water (brine),

$$\begin{aligned}\dot{Q}_{\text{brine}} &= \dot{m}_{\text{brine}} c_p (T_2 - T_1) \\ -22,790,000 \text{ Btu/h} &= (384,286 \text{ lbm/h})(1.03 \text{ Btu/lbm} \cdot ^\circ\text{F})(T_2 - 325^\circ\text{F}) \\ T_2 &= \mathbf{267.4^\circ\text{F}}\end{aligned}$$

(b) The rate of heat rejection from the working fluid to the air in the condenser is determined from the steady-flow energy balance on air,

$$\begin{aligned}\dot{Q}_{\text{air}} &= \dot{m}_{\text{air}} c_p (T_9 - T_8) \\ &= (4,195,100 \text{ lbm/h})(0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(84.5 - 55^\circ\text{F}) \\ &= \mathbf{29.7 \text{ MBtu/h}}\end{aligned}$$

(c) The mass flow rate of geothermal water at the preheater is determined from the steady-flow energy balance on the geothermal water,

$$\begin{aligned}\dot{Q}_{\text{geo}} &= \dot{m}_{\text{geo}} c_p (T_{\text{out}} - T_{\text{in}}) \\ -11,140,000 \text{ Btu/h} &= \dot{m}_{\text{geo}} (1.03 \text{ Btu/lbm} \cdot ^\circ\text{F})(154.0 - 211.8^\circ\text{F}) \\ \dot{m}_{\text{geo}} &= \mathbf{187,120 \text{ lbm/h}}\end{aligned}$$

(d) The rate of heat input is

$$\begin{aligned}\dot{Q}_{\text{in}} &= \dot{Q}_{\text{vaporizer}} + \dot{Q}_{\text{reheater}} = 22,790,000 + 11,140,000 \\ &= 33,930,000 \text{ Btu/h}\end{aligned}$$

and

$$\dot{W}_{\text{net}} = 1271 - 200 = 1071 \text{ kW}$$

Then,

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1071 \text{ kW}}{33,930,000 \text{ Btu/h}} \left( \frac{3412.14 \text{ Btu}}{1 \text{ kWh}} \right) = \mathbf{10.8\%}$$

**10-101** A steam power plant operating on an ideal Rankine cycle with two stages of reheat is considered. The thermal efficiency of the cycle and the mass flow rate of the steam are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 5 \text{ kPa} = 137.75 \text{ kJ/kg}$$

$$v_1 = v_f @ 5 \text{ kPa} = 0.001005 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001005 \text{ m}^3/\text{kg})(15,000 - 5 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.07 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 137.75 + 15.07 = 152.82 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 15 \text{ MPa} \\ T_3 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3310.8 \text{ kJ/kg} \\ s_3 = 6.3480 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 5 \text{ MPa} \\ s_4 = s_3 \end{array} \right\} h_4 = 3007.4 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 5 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3434.7 \text{ kJ/kg} \\ s_5 = 6.9781 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 1 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} h_6 = 2971.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_7 = 1 \text{ MPa} \\ T_7 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_7 = 3479.1 \text{ kJ/kg} \\ s_7 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_8 = 5 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} \begin{array}{l} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{7.7642 - 0.4762}{7.9176} = 0.9204 \\ h_8 = h_f + x_8 h_{fg} = 137.75 + (0.9204)(2423.0) = 2367.9 \text{ kJ/kg} \end{array}$$

Then,

$$\begin{aligned} q_{\text{in}} &= (h_3 - h_2) + (h_5 - h_4) + (h_7 - h_6) \\ &= 3310.8 - 152.82 + 3434.7 - 3007.4 + 3479.1 - 2971.3 = 4093.1 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{out}} = h_8 - h_1 = 2367.9 - 137.75 = 2230.2 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 4093.1 - 2230.2 = 1862.9 \text{ kJ/kg}$$

Thus,

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1862.9 \text{ kJ/kg}}{4093.1 \text{ kJ/kg}} = \mathbf{45.5\%}$$

$$(b) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{120,000 \text{ kJ/s}}{1862.9 \text{ kJ/kg}} = \mathbf{64.4 \text{ kg/s}}$$

**10-102** A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The thermal efficiency of the cycle is to be compared when it is operated so that the liquid enters the pump as a saturated liquid against that when the liquid enters as a subcooled liquid.

determined power produced by the turbine and consumed by the pump are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned} h_1 &= h_{f@50\text{ kPa}} = 340.54 \text{ kJ/kg} \\ \nu_1 &= \nu_{f@20\text{ kPa}} = 0.001030 \text{ m}^3/\text{kg} \\ w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(6000 - 50) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.13 \text{ kJ/kg} \\ h_2 &= h_1 + w_{p,\text{in}} = 340.54 + 6.13 = 346.67 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{aligned} P_3 &= 6000 \text{ kPa} \\ T_3 &= 600^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_3 &= 3658.8 \text{ kJ/kg} \\ s_3 &= 7.1693 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_4 &= 50 \text{ kPa} \\ s_4 &= s_3 \end{aligned} \right\} \begin{aligned} x_4 &= \frac{s_4 - s_f}{s_{fg}} = \frac{7.1693 - 1.0912}{6.5019} = 0.9348 \\ h_4 &= h_f + x_4 h_{fg} = 340.54 + (0.9348)(2304.7) = 2495.0 \text{ kJ/kg} \end{aligned}$$

Thus,

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = 3658.8 - 346.67 = 3312.1 \text{ kJ/kg} \\ q_{\text{out}} &= h_4 - h_1 = 2495.0 - 340.54 = 2154.5 \text{ kJ/kg} \end{aligned}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2154.5}{3312.1} = \mathbf{0.3495}$$

When the liquid enters the pump 11.3°C cooler than a saturated liquid at the condenser pressure, the enthalpies become

$$\left. \begin{aligned} P_1 &= 50 \text{ kPa} \\ T_1 &= T_{\text{sat}@50\text{ kPa}} - 11.3 = 81.3 - 11.3 = 70^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &\cong h_{f@70^\circ\text{C}} = 293.07 \text{ kJ/kg} \\ \nu_1 &\cong \nu_{f@70^\circ\text{C}} = 0.001023 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001023 \text{ m}^3/\text{kg})(6000 - 50) \text{ kPa} \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.09 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 293.07 + 6.09 = 299.16 \text{ kJ/kg}$$

Then,

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = 3658.8 - 299.16 = 3359.6 \text{ kJ/kg} \\ q_{\text{out}} &= h_4 - h_1 = 2495.0 - 293.09 = 2201.9 \text{ kJ/kg} \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2201.9}{3359.6} = \mathbf{0.3446}$$

The thermal efficiency slightly decreases as a result of subcooling at the pump inlet.

**10-103** An 150-MW steam power plant operating on a regenerative Rankine cycle with an open feedwater heater is considered. The mass flow rate of steam through the boiler, the thermal efficiency of the cycle, and the irreversibility associated with the regeneration process are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis**

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1)/\eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(500 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) \\ &= 0.52 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 191.81 + 0.52 = 192.33 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.5 \text{ MPa} \\ \text{sat liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg} \\ v_3 = v_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned} w_{pII,in} &= v_3(P_4 - P_3)/\eta_p \\ &= (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) \\ &= 10.93 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII,in} = 640.09 + 10.93 = 651.02 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.5995 - 1.8604}{4.9603} = 0.9554$$

$$\left. \begin{array}{l} P_{6s} = 0.5 \text{ MPa} \\ s_{6s} = s_5 \end{array} \right\} \begin{array}{l} h_{6s} = h_f + x_{6s} h_{fg} = 640.09 + (0.9554)(2108.0) \\ = 2654.1 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s})$$

$$= 3375.1 - (0.80)(3375.1 - 2654.1)$$

$$= 2798.3 \text{ kJ/kg}$$

$$x_{7s} = \frac{s_{7s} - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = 0.7934$$

$$\left. \begin{array}{l} P_{7s} = 10 \text{ kPa} \\ s_{7s} = s_5 \end{array} \right\} h_{7s} = h_f + x_{7s} h_{fg} = 191.81 + (0.7934)(2392.1)$$

$$= 2089.7 \text{ kJ/kg}$$

$$\eta_T = \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T(h_5 - h_{7s})$$

$$= 3375.1 - (0.80)(3375.1 - 2089.7)$$

$$= 2346.8 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that  $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ ,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi_0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = 1(h_3)$$

where  $y$  is the fraction of steam extracted from the turbine ( $= \dot{m}_6 / \dot{m}_3$ ). Solving for  $y$ ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{640.09 - 192.33}{2798.3 - 192.33} = 0.1718$$

Then,

$$q_{\text{in}} = h_5 - h_4 = 3375.1 - 651.02 = 2724.1 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y)(h_7 - h_1) = (1 - 0.1718)(2346.8 - 191.81) = 1784.7 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2724.1 - 1784.7 = 939.4 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150,000 \text{ kJ/s}}{939.4 \text{ kJ/kg}} = \mathbf{159.7 \text{ kg/s}}$$

(b) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1784.7 \text{ kJ/kg}}{2724.1 \text{ kJ/kg}} = \mathbf{34.5\%}$$

Also,

$$\left. \begin{array}{l} P_6 = 0.5 \text{ MPa} \\ h_6 = 2798.3 \text{ kJ/kg} \end{array} \right\} s_6 = 6.9453 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_f @ 0.5 \text{ MPa} = 1.8604 \text{ kJ/kg} \cdot \text{K}$$

$$s_2 = s_1 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

Then the irreversibility (or exergy destruction) associated with this regeneration process is

$$i_{\text{regen}} = T_0 s_{\text{gen}} = T_0 \left( \sum \dot{m}_e s_e - \sum \dot{m}_i s_i + \frac{q_{\text{surr}}}{T_L} \right) \stackrel{\phi_0}{=} T_0 [s_3 - y s_6 - (1 - y) s_2]$$

$$= (303 \text{ K}) [1.8604 - (0.1718)(6.9453) - (1 - 0.1718)(0.6492)] = \mathbf{39.25 \text{ kJ/kg}}$$

**10-104** An 150-MW steam power plant operating on an ideal regenerative Rankine cycle with an open feedwater heater is considered. The mass flow rate of steam through the boiler, the thermal efficiency of the cycle, and the irreversibility associated with the regeneration process are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis**

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI,in} = \nu_1 (P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(500 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.50 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,in} = 191.81 + 0.50 = 192.30 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.5 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg} \\ \nu_3 = \nu_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg} \end{array}$$

$$w_{pII,in} = \nu_3 (P_4 - P_3) = (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 10.38 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII,in} = 640.09 + 10.38 = 650.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 0.5 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.5995 - 1.8604}{4.9603} = 0.9554 \\ h_6 = h_f + x_6 h_{fg} = 640.09 + (0.9554)(2108.0) = 2654.1 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_7 = 10 \text{ kPa} \\ s_7 = s_5 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = 0.7934 \\ h_7 = h_f + x_7 h_{fg} = 191.81 + (0.7934)(2392.1) = 2089.7 \text{ kJ/kg} \end{array}$$

The fraction of steam extracted is determined from the steady-flow energy equation applied to the feedwater heaters. Noting that  $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ ,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1-y) h_2 = 1(h_3)$$

where  $y$  is the fraction of steam extracted from the turbine ( $= \dot{m}_6 / \dot{m}_3$ ). Solving for  $y$ ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{640.09 - 192.31}{2654.1 - 192.31} = 0.1819$$

Then,

$$q_{\text{in}} = h_3 - h_4 = 3375.1 - 650.47 = 2724.6 \text{ kJ/kg}$$

$$q_{\text{out}} = (1-y)(h_7 - h_1) = (1-0.1819)(2089.7 - 191.81) = 1552.7 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2724.6 - 1552.7 = 1172.0 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150,000 \text{ kJ/s}}{1171.9 \text{ kJ/kg}} = \mathbf{128.0 \text{ kg/s}}$$

$$\eta_T = \frac{h_7 - h_8}{h_7 - h_{8s}} \longrightarrow h_8 = h_7 - \eta_T(h_7 - h_{8s}) = 3479.1 - (0.84)(3479.1 - 3310.2) = 3337.2 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{9s} = 15 \text{ kPa} \\ s_{9s} = s_7 \end{array} \right\} \begin{array}{l} x_{9s} = \frac{s_{9s} - s_f}{s_{fg}} = \frac{7.7642 - 0.7549}{7.2522} = 0.9665 \\ h_{9s} = h_f + x_{9s}h_{fg} = 225.94 + (0.9665)(2372.3) = 2518.8 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_7 - h_9}{h_7 - h_{9s}} \longrightarrow h_9 = h_7 - \eta_T(h_7 - h_{9s}) = 3479.1 - (0.84)(3479.1 - 2518.8) = 2672.5 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that  $\dot{Q} \cong \dot{W} \cong \Delta \text{ke} \cong \Delta \text{pe} \cong 0$ ,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_8 + (1 - y) h_2 = 1(h_3) \end{aligned}$$

where  $y$  is the fraction of steam extracted from the turbine ( $= \dot{m}_8 / \dot{m}_3$ ). Solving for  $y$ ,

$$y = \frac{h_3 - h_2}{h_8 - h_2} = \frac{670.38 - 226.53}{3335.3 - 226.53} = \mathbf{0.1427}$$

(b) The thermal efficiency is determined from

$$\begin{aligned} q_{\text{in}} &= (h_5 - h_4) + (h_7 - h_6) \\ &= (3375.1 - 680.73) + (3479.1 - 2878.4) = 3295.1 \text{ kJ/kg} \\ q_{\text{out}} &= (1 - y)(h_9 - h_1) = (1 - 0.1427)(2672.5 - 225.94) = 2097.2 \text{ kJ/kg} \end{aligned}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2097.2 \text{ kJ/kg}}{3295.1 \text{ kJ/kg}} = \mathbf{36.4\%}$$

**10-107** A steam power plant operating on the ideal reheat-regenerative Rankine cycle with three feedwater heaters is considered. Various items for this system per unit of mass flow rate through the boiler are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** The compression processes in the pumps and the expansion processes in the turbines are isentropic. Also, the state of water at the inlet of pumps is saturated liquid. Then, from the steam tables (Tables A-4, A-5, and A-6),

|                                 |                                 |
|---------------------------------|---------------------------------|
| $h_1 = 191.81 \text{ kJ/kg}$    | $h_{13} = 3139.4 \text{ kJ/kg}$ |
| $h_2 = 191.90 \text{ kJ/kg}$    | $h_{14} = 3062.8 \text{ kJ/kg}$ |
| $h_3 = 417.51 \text{ kJ/kg}$    | $h_{15} = 2931.8 \text{ kJ/kg}$ |
| $h_4 = 421.05 \text{ kJ/kg}$    | $h_{16} = 2470.4 \text{ kJ/kg}$ |
| $h_5 = 1049.7 \text{ kJ/kg}$    | $h_{17} = 3275.5 \text{ kJ/kg}$ |
| $h_6 = 1052.8 \text{ kJ/kg}$    | $h_{18} = 2974.6 \text{ kJ/kg}$ |
| $h_9 = 1213.8 \text{ kJ/kg}$    | $h_{19} = 2547.5 \text{ kJ/kg}$ |
| $h_{10} = 1216.2 \text{ kJ/kg}$ |                                 |

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure. Then,

$$\left. \begin{array}{l} P_7 = 3500 \text{ kPa} \\ T_7 = T_5 = 242.6^\circ\text{C} \end{array} \right\} h_7 = 1050.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{11} = 6000 \text{ kPa} \\ T_{11} = T_9 = 275.6^\circ\text{C} \end{array} \right\} h_{11} = 1213.1 \text{ kJ/kg}$$

Enthalpies at other states and the fractions of steam extracted from the turbines can be determined from mass and energy balances on cycle components as follows:

Mass Balances:

$$x + y + z = 1$$

$$m + n = z$$

Open feedwater heater:

$$mh_{18} + nh_2 = zh_3$$

Closed feedwater heater-II:

$$zh_4 + yh_{15} = zh_7 + yh_5$$

Closed feedwater heater-I:

$$(y + z)h_8 + xh_{14} = (y + z)h_{11} + xh_9$$

Mixing chamber after closed feedwater heater II:

$$zh_7 + yh_6 = (y + z)h_8$$

Mixing chamber after closed feedwater heater I:

$$xh_{10} + (y + z)h_{11} = 1h_{12}$$

Substituting the values and solving the above equations simultaneously using EES, we obtain

$$h_8 = 1050.7 \text{ kJ/kg}$$

$$h_{12} = 1213.3 \text{ kJ/kg}$$

$$x = \mathbf{0.08072}$$

$$y = \mathbf{0.2303}$$

$$z = 0.6890$$

$$m = \mathbf{0.05586}$$

$$n = \mathbf{0.6332}$$

Note that these values may also be obtained by a hand solution by using the equations above with some rearrangements and substitutions. Other results of the cycle are

$$w_{T,\text{out,HP}} = x(h_{13} - h_{14}) + y(h_{13} - h_{15}) + z(h_{13} - h_{16}) = \mathbf{514.9 \text{ kJ/kg}}$$

$$w_{T,\text{out,LP}} = m(h_{17} - h_{18}) + n(h_{17} - h_{19}) = \mathbf{477.8 \text{ kJ/kg}}$$

$$q_{\text{in}} = h_{13} - h_{12} + z(h_{17} - h_{16}) = \mathbf{2481 \text{ kJ/kg}}$$

$$q_{\text{out}} = n(h_{19} - h_1) = \mathbf{1492 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1492}{2481} = \mathbf{0.3986}$$

**10-108 EES** The optimum bleed pressure for the open feedwater heater that maximizes the thermal efficiency of the cycle is to be determined using EES.

**Analysis** The EES program used to solve this problem as well as the solutions are given below.

**10-109E** A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The thermal efficiency of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable for Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left( \frac{P_6}{P_5} \right)^{(k-1)/k} = (540 \text{ R})(10)^{0.4/1.4} = 1043 \text{ R}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\begin{aligned} \longrightarrow T_6 &= T_5 + \frac{T_{6s} - T_5}{\eta_C} \\ &= 540 + \frac{1043 - 540}{0.90} = 1099 \text{ R} \end{aligned}$$

$$T_{8s} = T_7 \left( \frac{P_8}{P_7} \right)^{(k-1)/k} = (2560 \text{ R}) \left( \frac{1}{10} \right)^{0.4/1.4} = 1326 \text{ R}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} = \frac{c_p(T_7 - T_8)}{c_p(T_7 - T_{8s})} \longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 2560 - (0.90)(2560 - 1326) \\ &= 1449 \text{ R} \end{aligned}$$

$$T_9 = T_{\text{sat @ } 800 \text{ psia}} + 50 = 978.3 \text{ R} + 50 = 1028 \text{ R}$$

Fixing the states around the bottom steam cycle yields (Tables A-4E, A-5E, A-6E):

$$h_1 = h_f @ 5 \text{ psia} = 130.18 \text{ Btu/lbm}$$

$$\nu_1 = \nu_f @ 5 \text{ psia} = 0.01641 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lbm})(800 - 5) \text{ psia} \left( \frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 2.41 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 130.18 + 2.41 = 132.59 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1270.9 \text{ Btu/lbm} \\ s_3 = 1.4866 \text{ Btu/lbm}\cdot\text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 5 \text{ psia} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 908.6 \text{ Btu/lbm}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1270.9 - (0.95)(1270.9 - 908.6) \\ &= 926.7 \text{ Btu/lbm} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned}
 w_{\text{net, gas cycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\
 &= c_p (T_7 - T_8) - c_p (T_6 - T_5) \\
 &= (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1449 - 1099 + 540)\text{R} \\
 &= 132.5 \text{ Btu/lbm}
 \end{aligned}$$

$$\begin{aligned}
 w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\
 &= (h_3 - h_4) - w_{P,\text{in}} \\
 &= (1270.9 - 926.7) - 2.41 \\
 &= 341.8 \text{ Btu/lbm}
 \end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(0.240)(1449 - 1028)}{1270.9 - 132.59} = 0.08876 \dot{m}_a$$

That is, 1 lbm of exhaust gases can heat only 0.08876 lbm of water. Then the heat input, the heat output and the thermal efficiency are

$$q_{\text{in}} = \frac{\dot{m}_a}{\dot{m}_a} c_p (T_7 - T_6) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1099)\text{R} = 350.6 \text{ Btu/lbm}$$

$$\begin{aligned}
 q_{\text{out}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_9 - T_1) + \frac{\dot{m}_w}{\dot{m}_a} (h_4 - h_1) \\
 &= 1 \times (0.240 \text{ Btu/lbm} \cdot \text{R})(1028 - 540)\text{R} + 0.08876 \times (926.7 - 130.18) \text{ Btu/lbm} \\
 &= 187.8 \text{ Btu/lbm}
 \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{187.8}{350.6} = \mathbf{0.4643}$$

**10-110E** A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The thermal efficiency of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left( \frac{P_6}{P_5} \right)^{(k-1)/k} = (540 \text{ R})(10)^{0.4/1.4} = 1043 \text{ R}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

$$= 1270.9 - (0.95)(1270.9 - 946.6)$$

$$= 962.8 \text{ Btu/lbm}$$

The net work outputs from each cycle are

$$w_{\text{net, gas cycle}} = w_{T,\text{out}} - w_{C,\text{in}}$$

$$= c_p (T_7 - T_8) - c_p (T_6 - T_5)$$

$$= (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1449 - 1099 + 540)\text{R}$$

$$= 132.5 \text{ Btu/lbm}$$

$$w_{\text{net, steam cycle}} = w_{T,\text{out}} - w_{P,\text{in}}$$

$$= (h_3 - h_4) - w_{P,\text{in}}$$

$$= (1270.9 - 962.8) - 2.43$$

$$= 305.7 \text{ Btu/lbm}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(0.240)(1449 - 1028)}{1270.9 - 163.7} = 0.09126 \dot{m}_a$$

That is, 1 lbm of exhaust gases can heat only 0.09126 lbm of water. Then the heat input, the heat output and the thermal efficiency are

$$q_{\text{in}} = \frac{\dot{m}_a}{\dot{m}_a} c_p (T_7 - T_6) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1099)\text{R} = 350.6 \text{ Btu/lbm}$$

$$q_{\text{out}} = \frac{\dot{m}_a}{\dot{m}_a} c_p (T_9 - T_1) + \frac{\dot{m}_w}{\dot{m}_a} (h_4 - h_1)$$

$$= 1 \times (0.240 \text{ Btu/lbm} \cdot \text{R})(1028 - 540)\text{R} + 0.09126 \times (962.8 - 161.25) \text{ Btu/lbm}$$

$$= 190.3 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{190.3}{350.6} = \mathbf{0.4573}$$

When the condenser pressure is increased from 5 psia to 10 psia, the thermal efficiency is decreased from 0.4643 to 0.4573.

**10-111E** A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The cycle supplies a specified rate of heat to the buildings during winter. The mass flow rate of air and the net power output from the cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist.

2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** The mass flow rate of water is

$$\dot{m}_w = \frac{\dot{Q}_{\text{buildings}}}{h_4 - h_1} = \frac{2 \times 10^6 \text{ Btu/h}}{(962.8 - 161.25) \text{ Btu/lbm}} = 2495 \text{ lbm/h}$$

The mass flow rate of air is then

$$\dot{m}_w = \frac{\dot{m}_a}{0.09126} = \frac{2495}{0.09126} = \mathbf{27,340 \text{ lbm/h}}$$

The power outputs from each cycle are

$$\begin{aligned} \dot{W}_{\text{net, gas cycle}} &= \dot{m}_a (w_{T,\text{out}} - w_{C,\text{in}}) \\ &= c_p (T_7 - T_8) - c_p (T_6 - T_5) \\ &= (27,340 \text{ lbm/h})(0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1449 - 1099 + 540) \text{R} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) \\ &= 1062 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{W}_{\text{net, steam cycle}} &= \dot{m}_a (w_{T,\text{out}} - w_{P,\text{in}}) \\ &= \dot{m}_a (h_3 - h_4 - w_{P,\text{in}}) \\ &= (2495 \text{ lbm/h})(1270.9 - 962.8 - 2.43) \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) \\ &= 224 \text{ kW} \end{aligned}$$

The net electricity production by this cycle is then

$$\dot{W}_{\text{net}} = 1062 + 224 = \mathbf{1286 \text{ kW}}$$

**10-112** A combined gas-steam power plant is considered. The topping cycle is an ideal gas-turbine cycle and the bottoming cycle is an ideal reheat Rankine cycle. The mass flow rate of air in the gas-turbine cycle, the rate of total heat input, and the thermal efficiency of the combined cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) The analysis of gas cycle yields

$$T_7 = 290 \text{ K} \longrightarrow h_7 = 290.16 \text{ kJ/kg}$$

$$P_{r_7} = 1.2311$$

$$P_{r_8} = \frac{P_8}{P_7} P_{r_7} = (8)(1.2311) = 9.849 \longrightarrow h_8 = 526.12 \text{ kJ/kg}$$

$$T_9 = 1400 \text{ K} \longrightarrow h_9 = 1515.42 \text{ kJ/kg}$$

$$P_{r_9} = 450.5$$

$$P_{r_{10}} = \frac{P_{10}}{P_9} P_{r_9} = \left(\frac{1}{8}\right)(450.5) = 56.3 \longrightarrow h_{10} = 860.35 \text{ kJ/kg}$$

$$T_{11} = 520 \text{ K} \longrightarrow h_{11} = 523.63 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pl,in} = v_1(P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 15.14 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pl,in} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 15 \text{ MPa} \\ T_3 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3157.9 \text{ kJ/kg} \\ s_3 = 6.1434 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 3 \text{ MPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.1434 - 2.6454}{3.5402} = 0.9880 \\ h_4 = h_f + x_4 h_{fg} = 1008.3 + (0.9880)(1794.9) = 2781.7 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_5 = 3 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3457.2 \text{ kJ/kg} \\ s_5 = 7.2359 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.2355 - 0.6492}{7.4996} = 0.8783 \\ h_6 = h_f + x_6 h_{fg} = 191.81 + (0.8783)(2392.1) = 2292.8 \text{ kJ/kg} \end{array}$$

Noting that  $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$  for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{in} = \dot{E}_{out} \longrightarrow \sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_3 - h_2) = \dot{m}_{air} (h_{10} - h_{11})$$

$$\dot{m}_{air} = \frac{h_3 - h_2}{h_{10} - h_{11}} \dot{m}_s = \frac{3157.9 - 206.95}{860.35 - 523.63} (30 \text{ kg/s}) = \mathbf{262.9 \text{ kg/s}}$$

$$\begin{aligned}
 (b) \quad \dot{Q}_{\text{in}} &= \dot{Q}_{\text{air}} + \dot{Q}_{\text{reheat}} = \dot{m}_{\text{air}}(h_9 - h_8) + \dot{m}_{\text{reheat}}(h_5 - h_4) \\
 &= (262.9 \text{ kg/s})(1515.42 - 526.12) \text{ kJ/kg} + (30 \text{ kg/s})(3457.2 - 2781.7) \text{ kJ/kg} \\
 &= 280,352 \text{ kW} \\
 &\cong \mathbf{2.80 \times 10^5 \text{ kW}}
 \end{aligned}$$

$$\begin{aligned}
 (c) \quad \dot{Q}_{\text{out}} &= \dot{Q}_{\text{out,air}} + \dot{Q}_{\text{out,steam}} = \dot{m}_{\text{air}}(h_{11} - h_7) + \dot{m}_s(h_6 - h_1) \\
 &= (262.9 \text{ kg/s})(523.63 - 290.16) \text{ kJ/kg} + (30 \text{ kg/s})(2292.8 - 191.81) \text{ kJ/kg} \\
 &= 124,409 \text{ kW} \\
 \eta_{\text{th}} &= 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{124,409 \text{ kW}}{280,352 \text{ kW}} = \mathbf{55.6\%}
 \end{aligned}$$

**10-113** A combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal reheat Rankine cycle. The mass flow rate of air in the gas-turbine cycle, the rate of total heat input, and the thermal efficiency of the combined cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) The analysis of gas cycle yields (Table A-17)

$$T_7 = 290 \text{ K} \longrightarrow h_7 = 290.16 \text{ kJ/kg}$$

$$P_{r_7} = 1.2311$$

$$P_{r_{8s}} = \frac{P_{8s}}{P_7} P_{r_7} = (8)(1.2311) = 9.849 \longrightarrow h_{8s} = 526.12 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{8s} - h_7}{h_8 - h_7} \longrightarrow h_8 = h_7 + (h_{8s} - h_7)/\eta_C$$

$$= 290.16 + (526.12 - 290.16)/(0.80)$$

$$= 585.1 \text{ kJ/kg}$$

$$T_9 = 1400 \text{ K} \longrightarrow h_9 = 1515.42 \text{ kJ/kg}$$

$$P_{r_9} = 450.5$$

$$P_{r_{10s}} = \frac{P_{10s}}{P_9} P_{r_9} = \left(\frac{1}{8}\right)(450.5) = 56.3 \longrightarrow h_{10s} = 860.35 \text{ kJ/kg}$$

$$\eta_T = \frac{h_9 - h_{10}}{h_9 - h_{10s}} \longrightarrow h_{10} = h_9 - \eta_T(h_9 - h_{10s})$$

$$= 1515.42 - (0.85)(1515.42 - 860.35)$$

$$= 958.4 \text{ kJ/kg}$$

$$T_{11} = 520 \text{ K} \longrightarrow h_{11} = 523.63 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{p1,in} = v_1(P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 15.14 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p1,in} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 15 \text{ MPa} \\ T_3 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3157.9 \text{ kJ/kg} \\ s_3 = 6.1428 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 3 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} \begin{array}{l} x_{4s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.1434 - 2.6454}{3.5402} = 0.9880 \\ h_{4s} = h_f + x_{4s}h_{fg} = 1008.3 + (0.9879)(1794.9) = 2781.7 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s})$$

$$= 3157.9 - (0.85)(3157.9 - 2781.7)$$

$$= 2838.1 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_5 &= 3 \text{ MPa} \\ T_5 &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_5 &= 3457.2 \text{ kJ/kg} \\ s_5 &= 7.2359 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_6 &= 10 \text{ kPa} \\ s_{6s} &= s_5 \end{aligned} \right\} \begin{aligned} x_{6s} &= \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.2359 - 0.6492}{7.4996} = 0.8783 \\ h_{6s} &= h_f + x_{6s}h_{fg} = 191.81 + (0.8782)(2392.1) = 2292.8 \text{ kJ/kg} \end{aligned}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s})$$

$$= 3457.2 - (0.85)(3457.2 - 2292.8)$$

$$= 2467.5 \text{ kJ/kg}$$

Noting that  $\dot{Q} \cong \dot{W} \cong \Delta \text{ke} \cong \Delta \text{pe} \cong 0$  for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{\cong} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_s(h_3 - h_2) = \dot{m}_{\text{air}}(h_{10} - h_{11})$$

$$\dot{m}_{\text{air}} = \frac{h_3 - h_2}{h_{10} - h_{11}} \dot{m}_s = \frac{3157.9 - 206.95}{958.4 - 523.63} (30 \text{ kg/s}) = \mathbf{203.6 \text{ kg/s}}$$

$$(b) \quad \dot{Q}_{\text{in}} = \dot{Q}_{\text{air}} + \dot{Q}_{\text{reheat}} = \dot{m}_{\text{air}}(h_9 - h_8) + \dot{m}_{\text{reheat}}(h_5 - h_4)$$

$$= (203.6 \text{ kg/s})(1515.42 - 585.1) \text{ kJ/kg} + (30 \text{ kg/s})(3457.2 - 2838.1) \text{ kJ/kg}$$

$$= \mathbf{207,986 \text{ kW}}$$

$$(c) \quad \dot{Q}_{\text{out}} = \dot{Q}_{\text{out,air}} + \dot{Q}_{\text{out,steam}} = \dot{m}_{\text{air}}(h_{11} - h_7) + \dot{m}_s(h_6 - h_1)$$

$$= (203.6 \text{ kg/s})(523.63 - 290.16) \text{ kJ/kg} + (30 \text{ kg/s})(2467.5 - 191.81) \text{ kJ/kg}$$

$$= 115,805 \text{ kW}$$

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{115,805 \text{ kW}}{207,986 \text{ kW}} = \mathbf{44.3\%}$$

**10-114** It is to be shown that the exergy destruction associated with a simple ideal Rankine cycle can be expressed as  $x_{\text{destroyed}} = q_{\text{in}} (\eta_{\text{th,Carnot}} - \eta_{\text{th}})$ , where  $\eta_{\text{th}}$  is efficiency of the Rankine cycle and  $\eta_{\text{th,Carnot}}$  is the efficiency of the Carnot cycle operating between the same temperature limits.

**Analysis** The exergy destruction associated with a cycle is given on a unit mass basis as

$$x_{\text{destroyed}} = T_0 \sum \frac{q_R}{T_R}$$

where the direction of  $q_{\text{in}}$  is determined with respect to the reservoir (positive if to the reservoir and negative if from the reservoir). For a cycle that involves heat transfer only with a source at  $T_H$  and a sink at  $T_0$ , the irreversibility becomes

$$\begin{aligned} x_{\text{destroyed}} &= T_0 \left( \frac{q_{\text{out}}}{T_0} - \frac{q_{\text{in}}}{T_H} \right) = q_{\text{out}} - \frac{T_0}{T_H} q_{\text{in}} = q_{\text{in}} \left( \frac{q_{\text{out}}}{q_{\text{in}}} - \frac{T_0}{T_H} \right) \\ &= q_{\text{in}} \left[ (1 - \eta_{\text{th}}) - (1 - \eta_{\text{th,C}}) \right] = q_{\text{in}} (\eta_{\text{th,C}} - \eta_{\text{th}}) \end{aligned}$$

**10-115** A cogeneration plant is to produce power and process heat. There are two turbines in the cycle: a high-pressure turbine and a low-pressure turbine. The temperature, pressure, and mass flow rate of steam at the inlet of high-pressure turbine are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$P_4 = 1.4 \text{ MPa} \left\{ \begin{array}{l} h_4 = h_g @ 1.4 \text{ MPa} = 2788.9 \text{ kJ/kg} \\ \text{sat. vapor} \quad \left\{ \begin{array}{l} s_4 = s_g @ 1.4 \text{ MPa} = 6.4675 \text{ kJ/kg} \cdot \text{K} \\ x_{5s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.4675 - 0.6492}{7.4996} = 0.7758 \end{array} \right. \end{array} \right.$$

$$P_5 = 10 \text{ kPa} \left\{ \begin{array}{l} h_{5s} = h_f + x_{5s} h_{fg} \\ s_{5s} = s_4 \end{array} \right. \left\{ \begin{array}{l} = 191.81 + (0.7758)(2392.1) = 2047.6 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T (h_4 - h_{5s}) = 2788.9 - (0.60)(2788.9 - 2047.6) = 2344.1 \text{ kJ/kg}$$

and

$$w_{\text{turb,low}} = h_4 - h_5 = 2788.9 - 2344.1 = 444.8 \text{ kJ/kg}$$

$$\dot{m}_{\text{low turb}} = \frac{\dot{W}_{\text{turb,II}}}{w_{\text{turb,low}}} = \frac{800 \text{ kJ/s}}{444.8 \text{ kJ/kg}} = 1.799 \text{ kg/s} = 107.9 \text{ kg/min}$$

Therefore ,

$$\dot{m}_{\text{total}} = 1000 + 108 = 1108 \text{ kg/min} = \mathbf{18.47 \text{ kg/s}}$$

$$w_{\text{turb,high}} = \frac{\dot{W}_{\text{turb,I}}}{\dot{m}_{\text{high,turb}}} = \frac{1000 \text{ kJ/s}}{18.47 \text{ kg/s}} = 54.15 \text{ kJ/kg} = h_3 - h_4$$

$$h_3 = w_{\text{turb,high}} + h_4 = 54.15 + 2788.9 = 2843.0 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_{4s} = h_3 - (h_3 - h_4) / \eta_T = 2843.0 - (2843.0 - 2788.9) / (0.75) = 2770.8 \text{ kJ/kg}$$

$$P_{4s} = 1.4 \text{ MPa} \left\{ \begin{array}{l} x_{4s} = \frac{h_{4s} - h_f}{h_{fg}} = \frac{2770.8 - 829.96}{1958.9} = 0.9908 \\ s_{4s} = s_3 \end{array} \right. \left\{ \begin{array}{l} s_{4s} = s_f + x_{4s} s_{fg} = 2.2835 + (0.9908)(4.1840) = 6.4289 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

Then from the tables or the software, the turbine inlet temperature and pressure becomes

$$\left. \begin{array}{l} h_3 = 2843.0 \text{ kJ/kg} \\ s_3 = 6.4289 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} \begin{array}{l} P_3 = \mathbf{2 \text{ MPa}} \\ T_3 = \mathbf{227.5^\circ \text{C}} \end{array}$$

**10-116** A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The rate of process heat, the net power produced, and the utilization factor of the plant are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.001017 \text{ m}^3/\text{kg}) (2000 - 20 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.88 \\ &= 2.29 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 251.42 + 2.29 = 253.71 \text{ kJ/kg}$$

$$h_3 = h_f @ 2 \text{ MPa} = 908.47 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{m}_3 h_3 + \dot{m}_2 h_2 = \dot{m}_4 h_4$$

$$(4 \text{ kg/s})(908.47 \text{ kJ/kg}) + (11 - 4 \text{ kg/s})(253.71 \text{ kJ/kg}) = (11 \text{ kg/s})h_4 \longrightarrow h_4 = 491.81 \text{ kJ/kg}$$

$$\nu_4 \cong \nu_f @ h_f = 491.81 \text{ kJ/kg} = 0.001058 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_4 (P_5 - P_4) / \eta_p \\ &= (0.001058 \text{ m}^3/\text{kg}) (8000 - 2000 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.88 \\ &= 7.21 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 491.81 + 7.21 = 499.02 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_6 &= 8 \text{ MPa} \\ T_6 &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_6 &= 3399.5 \text{ kJ/kg} \\ s_6 &= 6.7266 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_7 &= 2 \text{ MPa} \\ s_7 &= s_6 \end{aligned} \right\} h_{7s} = 3000.4 \text{ kJ/kg}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} \longrightarrow h_7 = h_6 - \eta_T (h_6 - h_{7s}) = 3399.5 - (0.88)(3399.5 - 3000.4) = 3048.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 20 \text{ kPa} \\ s_8 = s_6 \end{array} \right\} h_{8s} = 2215.5 \text{ kJ/kg}$$

$$\eta_T = \frac{h_6 - h_8}{h_6 - h_{8s}} \longrightarrow h_8 = h_6 - \eta_T (h_6 - h_{8s}) = 3399.5 - (0.88)(3399.5 - 2215.5) = 2357.6 \text{ kJ/kg}$$

Then,

$$\dot{Q}_{\text{process}} = \dot{m}_7 (h_7 - h_3) = (4 \text{ kg/s})(3048.3 - 908.47) \text{ kJ/kg} = \mathbf{8559 \text{ kW}}$$

(b) Cycle analysis:

$$\begin{aligned} \dot{W}_{T,\text{out}} &= \dot{m}_7 (h_6 - h_7) + \dot{m}_8 (h_6 - h_8) \\ &= (4 \text{ kg/s})(3399.5 - 3048.3) \text{ kJ/kg} + (7 \text{ kg/s})(3399.5 - 2357.6) \text{ kJ/kg} \\ &= 8698 \text{ kW} \end{aligned}$$

$$\dot{W}_{p,\text{in}} = \dot{m}_1 w_{pI,\text{in}} + \dot{m}_4 w_{pII,\text{in}} = (7 \text{ kg/s})(2.29 \text{ kJ/kg}) + (11 \text{ kg/s})(7.21 \text{ kJ/kg}) = 95 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{T,\text{out}} - \dot{W}_{p,\text{in}} = 8698 - 95 = \mathbf{8603 \text{ kW}}$$

(c) Then,

$$\dot{Q}_{\text{in}} = \dot{m}_5 (h_6 - h_5) = (11 \text{ kg/s})(3399.5 - 499.02) = 31,905 \text{ kW}$$

and

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{8603 + 8559}{31,905} = 0.538 = \mathbf{53.8\%}$$

**10-117** A Rankine steam cycle modified for reheat, a closed feedwater heater, and an open feedwater heater is considered. The  $T$ - $s$  diagram for the ideal cycle is to be sketched. The net power output of the cycle and the minimum flow rate of the cooling water required are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 20 \text{ kPa} = 251.4 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.00102 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= \nu_1 (P_2 - P_1) \\ &= (0.00102 \text{ m}^3/\text{kg})(1400 - 20 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 1.41 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 251.4 + 1.41 = 252.8 \text{ kJ/kg}$$

$$h_4 = h_f @ 1400 \text{ kPa} = 830 \text{ kJ/kg}$$

$$\nu_4 = \nu_f @ 1400 \text{ kPa} = 0.00115 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII,in} &= \nu_4 (P_5 - P_4) \\ &= (0.00115 \text{ m}^3/\text{kg})(5000 - 1400 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 4.14 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII,in} = 830 + 4.14 = 834.1 \text{ kJ/kg}$$

Also,

$$h_3 = h_{12} = h_f @ 245 \text{ kPa} = 532 \text{ kJ/kg}$$

$$h_{13} = h_{12} \text{ (throttle valve operation)}$$

An energy balance on the open feedwater heater gives

$$yh_7 + (1-y)h_3 = 1(h_4)$$

where  $y$  is the fraction of steam extracted from the high-pressure turbine. Solving for  $y$ ,

$$y = \frac{h_4 - h_3}{h_7 - h_3} = \frac{830 - 532}{3400 - 532} = 0.1039$$

An energy balance on the closed feedwater heater gives

$$zh_{10} + (1-y)h_2 = (1-y)h_3 + zh_{12}$$

where  $z$  is the fraction of steam extracted from the low-pressure turbine. Solving for  $z$ ,

$$z = \frac{(1-y)(h_3 - h_2)}{h_{10} - h_{12}} = \frac{(1-0.1039)(532 - 252.8)}{3154 - 532} = 0.09542$$

The heat input in the boiler is

$$\begin{aligned} q_{in} &= (h_6 - h_5) + (1-y)(h_9 - h_8) \\ &= (3894 - 834.1) + (1-0.1039)(3692 - 3349) = 3367 \text{ kJ/kg} \end{aligned}$$

The work output from the turbines is

$$\begin{aligned}
 w_{T,\text{out}} &= h_6 - yh_7 - (1-y)h_8 + (1-y)h_9 - zh_{10} - (1-y-z)h_{11} \\
 &= 3894 - (0.1039)(3400) - (1-0.1039)(3349) \\
 &\quad + (1-0.1039)(3692) - (0.09542)(3154) - (1-0.1039-0.09542)(2620) \\
 &= 1449 \text{ kJ/kg}
 \end{aligned}$$

The net work output from the cycle is

$$\begin{aligned}
 w_{\text{net}} &= w_{T,\text{out}} - (1-y)w_{\text{PI},\text{in}} - w_{\text{PII},\text{in}} \\
 &= 1449 - (1-0.1039)(1.41) - 4.14 \\
 &= 1444 \text{ kJ/kg}
 \end{aligned}$$

The net power output is

$$\begin{aligned}
 \dot{W}_{\text{net}} &= \dot{m}w_{\text{net}} = (100 \text{ kg/s})(1444 \text{ kJ/kg}) \\
 &= 144,400 \text{ kW} = \mathbf{144.4 \text{ MW}}
 \end{aligned}$$

(c) The heat rejected from the condenser is

$$\begin{aligned}
 q_{\text{out}} &= (1-y-z)h_{11} + zh_{13} - (1-y)h_1 \\
 &= (1-0.1039-0.09542)(2620) + (0.09542)(532) - (1-0.1039)(251.4) \\
 &= 1923 \text{ kJ/kg}
 \end{aligned}$$

The mass flow rate of cooling water will be minimum when the cooling water exit temperature is a maximum. That is,

$$T_{w,2} = T_1 = T_{\text{sat @ } 20 \text{ kPa}} = 60.1^\circ\text{C}$$

Then an energy balance on the condenser gives

$$\begin{aligned}
 \dot{m}q_{\text{out}} &= \dot{m}_w c_{p,w} (T_{w,2} - T_{w,1}) \\
 \dot{m}_w &= \frac{\dot{m}q_{\text{out}}}{c_{p,w} (T_{w,2} - T_{w,1})} = \frac{(100 \text{ kg/s})(1923 \text{ kJ/kg})}{(4.18 \text{ kJ/kg} \cdot \text{K})(60.1 - 25) \text{ K}} = \mathbf{1311 \text{ kg/s}}
 \end{aligned}$$

**10-118** A Rankine steam cycle modified for reheat and three closed feedwater heaters is considered. The  $T$ - $s$  diagram for the ideal cycle is to be sketched. The net power output of the cycle and the flow rate of the cooling water required are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 10 \text{ kPa} = 191.8 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1) \\ &= (0.001010 \text{ m}^3/\text{kg})(5000 - 10 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.04 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 191.8 + 5.04 = 196.8 \text{ kJ/kg}$$

$$h_{16} = h_f @ 300 \text{ kPa} = 561.4 \text{ kJ/kg}$$

$$v_{16} = v_f @ 300 \text{ kPa} = 0.001073 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII,in} &= v_{16}(P_{17} - P_{16}) \\ &= (0.001073 \text{ m}^3/\text{kg})(5000 - 300 \text{ kPa}) \left( \frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.04 \text{ kJ/kg} \end{aligned}$$

$$h_{17} = h_{16} + w_{pII,in} = 561.4 + 5.04 = 566.4 \text{ kJ/kg}$$

Also,

$$h_3 = h_{18} = h_f @ 75 \text{ kPa} = 384.4 \text{ kJ/kg}$$

$$h_4 = h_{16} = h_f @ 300 \text{ kPa} = 561.4 \text{ kJ/kg}$$

$$h_5 = h_{14} = h_f @ 925 \text{ kPa} = 747.7 \text{ kJ/kg}$$

$$h_{15} = h_{14} \text{ (throttle valve operation)}$$

$$h_{19} = h_{18} \text{ (throttle valve operation)}$$

Energy balances on three closed feedwater heaters give

$$yh_{10} + (1 - y - z)h_4 = (1 - y - z)h_5 + yh_{15}$$

$$zh_{11} + (1 - y - z)h_3 + yh_{15} = (1 - y - z)h_4 + (y + z)h_{16}$$

$$wh_{12} + (1 - y - z)h_2 = (1 - y - z)h_3 + wh_{18}$$

The enthalpies are known, and thus there are three unknowns ( $y$ ,  $z$ ,  $w$ ) and three equations. Solving these equations using EES, we obtain

$$y = 0.06335$$

$$z = 0.05863$$

$$w = 0.07063$$

The enthalpy at state 6 may be determined from an energy balance on mixing chamber:

$$\begin{aligned} h_6 &= (1 - y - z)h_5 + (y + z)h_{17} \\ &= (1 - 0.06335 - 0.05863)(747.7) + (0.06335 + 0.05863)(566.4) = 725.6 \text{ kJ/kg} \end{aligned}$$

The heat input in the boiler is

$$\begin{aligned} q_{in} &= (h_7 - h_6) + (h_9 - h_8) \\ &= (3900 - 725.6) + (3687 - 3615) = 3246 \text{ kJ/kg} \end{aligned}$$

The work output from the turbines is

$$\begin{aligned}
 w_{T,\text{out}} &= h_7 - h_8 + h_9 - yh_{10} - zh_{11} - wh_{12} - (1 - y - z - w)h_{13} \\
 &= 3900 - 3615 + 3687 - (0.06335)(3330) - (0.05863)(3011) \\
 &\quad - (0.07063)(2716) - (1 - 0.06335 - 0.05863 - 0.07063)(2408) \\
 &= 1448 \text{ kJ/kg}
 \end{aligned}$$

The net work output from the cycle is

$$\begin{aligned}
 w_{\text{net}} &= w_{T,\text{out}} - (1 - y - z)w_{\text{PI},\text{in}} - (y + z)w_{\text{PII},\text{in}} \\
 &= 1448 - (1 - 0.06335 - 0.05863)(5.04) - (0.06335 + 0.05863)(5.04) \\
 &= 1443 \text{ kJ/kg}
 \end{aligned}$$

The net power output is

$$\begin{aligned}
 \dot{W}_{\text{net}} &= \dot{m}w_{\text{net}} = (100 \text{ kg/s})(1443 \text{ kJ/kg}) \\
 &= 144,300 \text{ kW} = \mathbf{144.3 \text{ MW}}
 \end{aligned}$$

(c) The heat rejected from the condenser is

$$\begin{aligned}
 q_{\text{out}} &= (1 - y - z - w)h_{13} + wh_{19} - (1 - y - z)h_1 \\
 &= (1 - 0.06335 - 0.05863 - 0.07063)(2408) + (0.07063)(384.4) - (1 - 0.06335 - 0.05863)(191.8) \\
 &= 1803 \text{ kJ/kg}
 \end{aligned}$$

Then an energy balance on the condenser gives

$$\begin{aligned}
 \dot{m}q_{\text{out}} &= \dot{m}_w c_{p,w} (T_{w,2} - T_{w,1}) \\
 \dot{m}_w &= \frac{\dot{m}q_{\text{out}}}{c_{p,w} (T_{w,2} - T_{w,1})} = \frac{(100 \text{ kg/s})(1803 \text{ kJ/kg})}{(4.18 \text{ kJ/kg} \cdot \text{K})(10 \text{ K})} = \mathbf{4313 \text{ kg/s}}
 \end{aligned}$$

**10-119 EES** The effect of the condenser pressure on the performance a simple ideal Rankine cycle is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

```

## Fundamentals of Engineering (FE) Exam Problems

**10-123** Consider a steady-flow Carnot cycle with water as the working fluid executed under the saturation dome between the pressure limits of 8 MPa and 20 kPa. Water changes from saturated liquid to saturated vapor during the heat addition process. The net work output of this cycle is

- (a) 494 kJ/kg      (b) 975 kJ/kg      (c) 596 kJ/kg      (d) 845 kJ/kg      (e) 1148 kJ/kg

*Answer* (c) 596 kJ/kg

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

P1=8000 "kPa"

P2=20 "kPa"

h\_fg=ENTHALPY(Steam\_IAPWS,x=1,P=P1)-ENTHALPY(Steam\_IAPWS,x=0,P=P1)

```

**10-127** Consider a combined gas-steam power plant. Water for the steam cycle is heated in a well-insulated heat exchanger by the exhaust gases that enter at 800 K at a rate of 60 kg/s and leave at 400 K. Water enters the heat exchanger at 200°C and 8 MPa and leaves at 350°C and 8 MPa. If the exhaust gases are treated as air with constant specific heats at room temperature, the mass flow rate of water through the heat exchanger becomes

- (a) 11 kg/s                      (b) 24 kg/s                      (c) 46 kg/s                      (d) 53 kg/s                      (e) 60 kg/s

*Answer* (a) 11 kg/s

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
m_gas=60 "kg/s"
Cp=1.005 "kJ/kg.K"
T3=800 "K"
T4=400 "K"
Q_gas=m_gas*Cp*(T3-T4)
P1=8000 "kPa"
T1=200 "C"
P2=8000 "kPa"
T2=350 "C"
h1=ENTHALPY(Steam_IAPWS,T=T1,P=P1)
h2=ENTHALPY(Steam_IAPWS,T=T2,P=P2)

W2_ext = h3/(h_extracted-h_feed) "Using wrong relation"
W3_ext = h_feed/(h_extracted-h_feed) "Using wrong relation"
```

**10-130** Consider a steam power plant that operates on the regenerative Rankine cycle with one open feedwater heater. The enthalpy of the steam is 3374 kJ/kg at the turbine inlet, 2797 kJ/kg at the location of bleeding, and 2346 kJ/kg at the turbine exit. The net power output of the plant is 120 MW, and the fraction of steam bled off the turbine for regeneration is 0.172. If the pump work is negligible, the mass flow rate of steam at the turbine inlet is

- (a) 117 kg/s                      (b) 126 kg/s                      (c) 219 kg/s                      (d) 288 kg/s                      (e) 679 kg/s

*Answer* (b) 126 kg/s

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
h_in=3374 "kJ/kg"
h_out=2346 "kJ/kg"
h_extracted=2797 "kJ/kg"
Wnet_out=120000 "kW"
x_bleed=0.172
w_turb=(h_in-h_extracted)+(1-x_bleed)*(h_extracted-h_out)
m=Wnet_out/w_turb
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_mass = Wnet_out/(h_in-h_out) "Disregarding extraction of steam"
W2_mass = Wnet_out/(x_bleed*(h_in-h_out)) "Assuming steam is extracted at turbine inlet"
W3_mass = Wnet_out/(h_in-h_out-x_bleed*h_extracted) "Using wrong relation"
```

**10-131** Consider a simple ideal Rankine cycle. If the condenser pressure is lowered while keeping turbine inlet state the same, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the cycle efficiency will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the pump work input will decrease.

*Answer* (b) the amount of heat rejected will decrease.

**10-132** Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the steam is superheated to a higher temperature, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the cycle efficiency will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the amount of heat input will decrease.

*Answer* (d) the moisture content at turbine exit will decrease.

**10-133** Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the cycle is modified with reheating, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the pump work input will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the amount of heat input will decrease.

*Answer* (d) the moisture content at turbine exit will decrease.

**10-134** Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the cycle is modified with regeneration that involves one open feed water heater, (select the correct statement per unit mass of steam flowing through the boiler)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will increase.
- (c) the cycle thermal efficiency will decrease.
- (d) the quality of steam at turbine exit will decrease.
- (e) the amount of heat input will increase.

*Answer* (a) the turbine work output will decrease.

**10-135** Consider a cogeneration power plant modified with regeneration. Steam enters the turbine at 6 MPa and 450°C at a rate of 20 kg/s and expands to a pressure of 0.4 MPa. At this pressure, 60% of the steam is extracted from the turbine, and the remainder expands to a pressure of 10 kPa. Part of the extracted steam is used to heat feedwater in an open feedwater heater. The rest of the extracted steam is used for process heating and leaves the process heater as a saturated liquid at 0.4 MPa. It is subsequently mixed with the feedwater leaving the feedwater heater, and the mixture is pumped to the boiler pressure. The steam in the condenser is cooled and condensed by the cooling water from a nearby river, which enters the adiabatic condenser at a rate of 463 kg/s.

1. The total power output of the turbine is

- (a) 17.0 MW      (b) 8.4 MW      (c) 12.2 MW      (d) 20.0 MW      (e) 3.4 MW

Answer (a) 17.0 MW

2. The temperature rise of the cooling water from the river in the condenser is

- (a) 8.0°C      (b) 5.2°C      (c) 9.6°C      (d) 12.9°C      (e) 16.2°C

Answer (a) 8.0°C

3. The mass flow rate of steam through the process heater is

- (a) 1.6 kg/s      (b) 3.8 kg/s      (c) 5.2 kg/s      (d) 7.6 kg/s      (e) 10.4 kg/s

Answer (e) 10.4 kg/s

4. The rate of heat supply from the process heater per unit mass of steam passing through it is

- (a) 246 kJ/kg      (b) 893 kJ/kg      (c) 1344 kJ/kg      (d) 1891 kJ/kg      (e) 2060 kJ/kg

Answer (e) 2060 kJ/kg

5. The rate of heat transfer to the steam in the boiler is

- (a) 26.0 MJ/s      (b) 53.8 MJ/s      (c) 39.5 MJ/s      (d) 62.8 MJ/s      (e) 125.4 MJ/s

Answer (b) 53.8 MJ/s

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

## 10-136 ... 10-143 Design and Essay Problems

# Chapter 11

## REFRIGERATION CYCLES

### The Reversed Carnot Cycle

**11-1C** Because the compression process involves the compression of a liquid-vapor mixture which requires a compressor that will handle two phases, and the expansion process involves the expansion of high-moisture content refrigerant.

**11-2** A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The coefficient of performance, the amount of heat absorbed from the refrigerated space, and the net work input are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Noting that  $T_H = 30^\circ\text{C} = 303\text{ K}$  and  $T_L = T_{\text{sat @ } 160\text{ kPa}} = -15.60^\circ\text{C} = 257.4\text{ K}$ , the COP of this Carnot refrigerator is determined from

$$\text{COP}_{\text{R,C}} = \frac{1}{T_H / T_L - 1} = \frac{1}{(303\text{ K}) / (257.4\text{ K}) - 1} = 5.64$$

(b) From the refrigerant tables (Table A-11),

$$h_3 = h_{g@30^\circ\text{C}} = 266.66\text{ kJ/kg}$$

$$h_4 = h_{f@30^\circ\text{C}} = 93.58\text{ kJ/kg}$$

Thus,

$$q_H = h_3 - h_4 = 266.66 - 93.58 = 173.08\text{ kJ/kg}$$

and

$$\frac{q_H}{q_L} = \frac{T_H}{T_L} \longrightarrow q_L = \frac{T_L}{T_H} q_H = \left( \frac{257.4\text{ K}}{303\text{ K}} \right) (173.08\text{ kJ/kg}) = 147.03\text{ kJ/kg}$$

(c) The net work input is determined from

$$w_{\text{net}} = q_H - q_L = 173.08 - 147.03 = 26.05\text{ kJ/kg}$$

**11-3E** A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The coefficient of performance, the quality at the beginning of the heat-absorption process, and the net work input are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) Noting that  $T_H = T_{\text{sat @ 90 psia}} = 72.78^\circ\text{F} = 532.8\text{ R}$  and  $T_L = T_{\text{sat @ 30 psia}} = 15.37^\circ\text{F} = 475.4\text{ R}$ .

$$\text{COP}_{\text{R,C}} = \frac{1}{T_H / T_L - 1} = \frac{1}{(532.8\text{ R}) / (475.4\text{ R}) - 1} = \mathbf{8.28}$$

(b) Process 4-1 is isentropic, and thus

$$s_1 = s_4 = (s_f + x_4 s_{fg})_{\text{@ 90 psia}} = 0.07481 + (0.05)(0.14525) \\ = 0.08207\text{ Btu/lbm} \cdot \text{R}$$

$$x_1 = \left( \frac{s_1 - s_f}{s_{fg}} \right)_{\text{@ 30 psia}} = \frac{0.08207 - 0.03793}{0.18589} = \mathbf{0.2374}$$

(c) Remembering that on a  $T$ - $s$  diagram the area enclosed represents the net work, and  $s_3 = s_g \text{ @ 90 psia} = 0.22006\text{ Btu/lbm} \cdot \text{R}$ ,

$$w_{\text{net,in}} = (T_H - T_L)(s_3 - s_4) = (72.78 - 15.37)(0.22006 - 0.08207)\text{ Btu/lbm} \cdot \text{R} = \mathbf{7.92\text{ Btu/lbm}}$$

## Ideal and Actual Vapor-Compression Cycles

**11-4C** Yes; the throttling process is an internally irreversible process.

**11-5C** To make the ideal vapor-compression refrigeration cycle more closely approximate the actual cycle.

**11-6C** No. Assuming the water is maintained at 10°C in the evaporator, the evaporator pressure will be the saturation pressure corresponding to this pressure, which is 1.2 kPa. It is not practical to design refrigeration or air-conditioning devices that involve such extremely low pressures.

**11-7C** Allowing a temperature difference of 10°C for effective heat transfer, the condensation temperature of the refrigerant should be 25°C. The saturation pressure corresponding to 25°C is 0.67 MPa. Therefore, the recommended pressure would be 0.7 MPa.

**11-8C** The area enclosed by the cyclic curve on a  $T$ - $s$  diagram represents the net work input for the reversed Carnot cycle, but not so for the ideal vapor-compression refrigeration cycle. This is because the latter cycle involves an irreversible process for which the process path is not known.

**11-9C** The cycle that involves saturated liquid at 30°C will have a higher COP because, judging from the  $T$ - $s$  diagram, it will require a smaller work input for the same refrigeration capacity.

**11-10C** The minimum temperature that the refrigerant can be cooled to before throttling is the temperature of the sink (the cooling medium) since heat is transferred from the refrigerant to the cooling medium.

**11-11** A commercial refrigerator with refrigerant-134a as the working fluid is considered. The quality of the refrigerant at the evaporator inlet, the refrigeration load, the COP of the refrigerator, and the theoretical maximum refrigeration load for the same power input to the compressor are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} P_1 &= 60 \text{ kPa} \\ T_1 &= -34^\circ\text{C} \end{aligned} \left\{ \begin{aligned} h_1 &= 230.03 \text{ kJ/kg} \end{aligned} \right.$$

$$\begin{aligned} P_2 &= 1200 \text{ kPa} \\ T_2 &= 65^\circ\text{C} \end{aligned} \left\{ \begin{aligned} h_2 &= 295.16 \text{ kJ/kg} \end{aligned} \right.$$

$$\begin{aligned} P_3 &= 1200 \text{ kPa} \\ T_3 &= 42^\circ\text{C} \end{aligned} \left\{ \begin{aligned} h_3 &= 111.23 \text{ kJ/kg} \end{aligned} \right.$$

$$h_4 = h_3 = 111.23 \text{ kJ/kg}$$

$$\begin{aligned} P_4 &= 60 \text{ kPa} \\ h_4 &= 111.23 \text{ kJ/kg} \end{aligned} \left\{ \begin{aligned} x_4 &= \mathbf{0.4795} \end{aligned} \right.$$

Using saturated liquid enthalpy at the given temperature, for water we have (Table A-4)

$$h_{w1} = h_f @ 18^\circ\text{C} = 75.47 \text{ kJ/kg}$$

$$h_{w2} = h_f @ 26^\circ\text{C} = 108.94 \text{ kJ/kg}$$

(b) The mass flow rate of the refrigerant may be determined from an energy balance on the compressor

$$\begin{aligned} \dot{m}_R(h_2 - h_3) &= \dot{m}_w(h_{w2} - h_{w1}) \\ \dot{m}_R(295.16 - 111.23) \text{ kJ/kg} &= (0.25 \text{ kg/s})(108.94 - 75.47) \text{ kJ/kg} \\ \longrightarrow \dot{m}_R &= 0.0455 \text{ kg/s} \end{aligned}$$

The waste heat transferred from the refrigerant, the compressor power input, and the refrigeration load are

$$\dot{Q}_H = \dot{m}_R(h_2 - h_3) = (0.0455 \text{ kg/s})(295.16 - 111.23) \text{ kJ/kg} = 8.367 \text{ kW}$$

$$\dot{W}_{\text{in}} = \dot{m}_R(h_2 - h_1) - \dot{Q}_{\text{in}} = (0.0455 \text{ kg/s})(295.16 - 230.03) \text{ kJ/kg} - 0.45 \text{ kW} = 2.513 \text{ kW}$$

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{\text{in}} = 8.367 - 2.513 = \mathbf{5.85 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{5.85}{2.513} = \mathbf{2.33}$$

(d) The reversible COP of the refrigerator for the same temperature limits is

$$\text{COP}_{\text{max}} = \frac{1}{T_H/T_L - 1} = \frac{1}{(18 + 273)/(-30 + 273) - 1} = 5.063$$

Then, the maximum refrigeration load becomes

$$\dot{Q}_{L,\text{max}} = \text{COP}_{\text{max}} \dot{W}_{\text{in}} = (5.063)(2.513 \text{ kW}) = \mathbf{12.72 \text{ kW}}$$

**11-12** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP and the power requirement are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 4^\circ\text{C} = 252.77 \text{ kJ/kg} \\ s_1 = s_g @ 4^\circ\text{C} = 0.92927 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 275.29 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1 \text{ MPa} = 107.32 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{400 \text{ kJ/s}}{(252.77 - 107.32) \text{ kJ/kg}} = 2.750 \text{ kg/s}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (2.750 \text{ kg/s})(275.29 - 252.77) \text{ kJ/kg} = \mathbf{61.93 \text{ kW}}$$

The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{400 \text{ kW}}{61.93 \text{ kW}} = \mathbf{6.46}$$

**11-13** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The mass flow rate of the refrigerant and the power requirement are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = 400 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 400 \text{ kPa} = 255.55 \text{ kJ/kg} \\ s_1 = s_g @ 400 \text{ kPa} = 0.92691 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 269.90 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 95.47 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{10 \text{ kJ/s}}{(255.55 - 95.47) \text{ kJ/kg}} = \mathbf{0.06247 \text{ kg/s}}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.06247 \text{ kg/s})(269.90 - 255.55) \text{ kJ/kg} = \mathbf{0.8964 \text{ kW}}$$

**11-14E** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The mass flow rate of the refrigerant and the power requirement are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} T_1 = -10^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -10^\circ\text{F} = 101.61 \text{ Btu/lbm} \\ s_1 = s_g @ -10^\circ\text{F} = 0.22660 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_2 = 100 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 117.57 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 100 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 100 \text{ psia} = 37.869 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 37.869 \text{ Btu/lbm} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{24,000 \text{ Btu/h}}{(101.61 - 37.869) \text{ Btu/lbm}} = \mathbf{376.5 \text{ lbm/h}}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (376.5 \text{ lbm/h})(117.57 - 101.61) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{1.761 \text{ kW}}$$

**11-15E** Problem 11-14E is to be repeated if ammonia is used as the refrigerant.

**Analysis** The problem is solved using EES, and the solution is given below.

**11-16** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the rate of heat rejection to the environment, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 120 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 120 \text{ kPa} = 236.97 \text{ kJ/kg} \\ s_1 = s_g @ 120 \text{ kPa} = 0.94779 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.7 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_2 = 273.50 \text{ kJ/kg} \quad (T_2 = 34.95^\circ\text{C}) \end{array}$$

$$\left. \begin{array}{l} P_3 = 0.7 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.7 \text{ MPa} = 88.82 \text{ kJ/kg} \end{array}$$

$$h_4 \cong h_3 = 88.82 \text{ kJ/kg} \quad (\text{throttling})$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.05 \text{ kg/s})(236.97 - 88.82) \text{ kJ/kg} = \mathbf{7.41 \text{ kW}}$$

and

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.05 \text{ kg/s})(273.50 - 236.97) \text{ kJ/kg} = \mathbf{1.83 \text{ kW}}$$

(b) The rate of heat rejection to the environment is determined from

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{\text{in}} = 7.41 + 1.83 = \mathbf{9.23 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{7.41 \text{ kW}}{1.83 \text{ kW}} = \mathbf{4.06}$$

**11-17** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the rate of heat rejection to the environment, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 120 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 120 \text{ kPa} = 236.97 \text{ kJ/kg} \\ s_1 = s_g @ 120 \text{ kPa} = 0.94779 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.9 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_2 = 278.93 \text{ kJ/kg} \quad (T_2 = 44.45^\circ\text{C}) \\ \end{array}$$

$$\left. \begin{array}{l} P_3 = 0.9 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 0.9 \text{ MPa} = 101.61 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 101.61 \text{ kJ/kg} \quad (\text{throttling})$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.05 \text{ kg/s})(236.97 - 101.61) \text{ kJ/kg} = \mathbf{6.77 \text{ kW}}$$

and

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.05 \text{ kg/s})(278.93 - 236.97) \text{ kJ/kg} = \mathbf{2.10 \text{ kW}}$$

(b) The rate of heat rejection to the environment is determined from

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{\text{in}} = 6.77 + 2.10 = \mathbf{8.87 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{6.77 \text{ kW}}{2.10 \text{ kW}} = \mathbf{3.23}$$

**11-18** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The throttling valve in the cycle is replaced by an isentropic turbine. The percentage increase in the COP and in the rate of heat removal from the refrigerated space due to this replacement are to be determined.

**Assumptions 1** Steady operating conditions exist.

**2** Kinetic and potential energy changes are negligible.

**Analysis** If the throttling valve in the previous problem is replaced by an isentropic turbine, we would have  $s_{4s} = s_3 = s_f @ 0.7 \text{ MPa} = 0.33230 \text{ kJ/kg}\cdot\text{K}$ , and the enthalpy at the turbine exit would be

$$x_{4s} = \left( \frac{s_3 - s_f}{s_{fg}} \right)_{@ 120 \text{ kPa}} = \frac{0.33230 - 0.09275}{0.85503} = 0.2802$$

$$h_{4s} = (h_f + x_{4s} h_{fg})_{@ 120 \text{ kPa}} = 22.49 + (0.2802)(214.48) = 82.58 \text{ kJ/kg}$$

Then,

$$\dot{Q}_L = \dot{m}(h_1 - h_{4s}) = (0.05 \text{ kg/s})(236.97 - 82.58) \text{ kJ/kg} = 7.72 \text{ kW}$$

and

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{7.72 \text{ kW}}{1.83 \text{ kW}} = 4.23$$

Then the percentage increase in  $\dot{Q}$  and COP becomes

$$\text{Increase in } \dot{Q}_L = \frac{\Delta \dot{Q}_L}{\dot{Q}_L} = \frac{7.72 - 7.41}{7.41} = \mathbf{4.2\%}$$

$$\text{Increase in } \text{COP}_R = \frac{\Delta \text{COP}_R}{\text{COP}_R} = \frac{4.23 - 4.06}{4.06} = \mathbf{4.2\%}$$

**11-19** A refrigerator with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the isentropic efficiency of the compressor, and the COP of the refrigerator are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 0.14 \text{ MPa} \\ T_1 = -10^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 246.36 \text{ kJ/kg} \\ s_1 = 0.97236 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.7 \text{ MPa} \\ T_2 = 50^\circ\text{C} \end{array} \right\} h_2 = 288.53 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{2s} = 0.7 \text{ MPa} \\ s_{2s} = s_1 \end{array} \right\} h_{2s} = 281.16 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.65 \text{ MPa} \\ T_3 = 24^\circ\text{C} \end{array} \right\} h_3 = h_f @ 24^\circ\text{C} = 84.98 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 84.98 \text{ kJ/kg (throttling)}$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.12 \text{ kg/s})(246.36 - 84.98) \text{ kJ/kg} = \mathbf{19.4 \text{ kW}}$$

and

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.12 \text{ kg/s})(288.53 - 246.36) \text{ kJ/kg} = \mathbf{5.06 \text{ kW}}$$

(b) The adiabatic efficiency of the compressor is determined from

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{281.16 - 246.36}{288.53 - 246.36} = \mathbf{82.5\%}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{19.4 \text{ kW}}{5.06 \text{ kW}} = \mathbf{3.83}$$

**11-20** An air conditioner operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP of the system is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. The evaporating temperature will be  $22-2=20^{\circ}\text{C}$ . From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 20^{\circ}\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 20^{\circ}\text{C} = 261.59 \text{ kJ/kg} \\ s_1 = s_g @ 20^{\circ}\text{C} = 0.92234 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 273.11 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1 \text{ MPa} = 107.32 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling})$$

The COP of the air conditioner is determined from its definition,

$$\text{COP}_{\text{AC}} = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{261.59 - 107.32}{273.11 - 261.59} = \mathbf{13.39}$$

**11-21E** A refrigerator operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The increase in the COP if the throttling process were replaced by an isentropic expansion is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\begin{aligned}
 & \left. \begin{array}{l} T_1 = 20^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 20^\circ\text{F} = 105.98 \text{ Btu/lbm} \\ s_1 = s_g @ 20^\circ\text{F} = 0.22341 \text{ Btu/lbm} \cdot \text{R} \end{array} \\
 & \left. \begin{array}{l} P_2 = 300 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 125.68 \text{ Btu/lbm} \\
 & \left. \begin{array}{l} P_3 = 300 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 300 \text{ psia} = 66.339 \text{ Btu/lbm} \\ s_3 = s_f @ 300 \text{ psia} = 0.12715 \text{ Btu/lbm} \cdot \text{R} \end{array} \\
 & h_4 \cong h_3 = 66.339 \text{ Btu/lbm} \quad (\text{throttling}) \\
 & \left. \begin{array}{l} T_4 = 15^\circ\text{F} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 59.80 \text{ Btu/lbm} \quad (\text{isentropic expansion})
 \end{aligned}$$

The COP of the refrigerator for the throttling case is

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{105.98 - 66.339}{125.68 - 105.98} = \mathbf{2.012}$$

The COP of the refrigerator for the isentropic expansion case is

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_{4s}}{h_2 - h_1} = \frac{105.98 - 59.80}{125.68 - 105.98} = \mathbf{2.344}$$

The increase in the COP by isentropic expansion is **16.5%**.

**11-22** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP of the system and the cooling load are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = -10^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -10^\circ\text{C} = 244.51 \text{ kJ/kg} \\ s_1 = s_g @ -10^\circ\text{C} = 0.93766 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 600 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 267.12 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 600 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 600 \text{ kPa} = 81.51 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 81.51 \text{ kJ/kg} \quad (\text{throttling})$$

The COP of the air conditioner is determined from its definition,

$$\text{COP}_{\text{AC}} = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{244.51 - 81.51}{267.12 - 244.51} = \mathbf{7.21}$$

The cooling load is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (7 \text{ kg/s})(244.51 - 81.51) \text{ kJ/kg} = \mathbf{1141 \text{ kW}}$$

**11-23** A refrigerator with refrigerant-134a as the working fluid is considered. The power input to the compressor, the rate of heat removal from the refrigerated space, and the pressure drop and the rate of heat gain in the line between the evaporator and the compressor are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 140 \text{ kPa} \\ T_1 = -10^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 246.36 \text{ kJ/kg} \\ s_1 = 0.97236 \text{ kJ/kg} \cdot \text{K} \\ v_1 = 0.14605 \text{ m}^3/\text{kg} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1.0 \text{ MPa} \\ s_{2s} = s_1 \end{array} \right\} \begin{array}{l} h_{2s} = 289.20 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_3 = 0.95 \text{ MPa} \\ T_3 = 30^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 \cong h_f @ 30^\circ\text{C} = 93.58 \text{ kJ/kg} \end{array}$$

$$h_4 \cong h_3 = 93.58 \text{ kJ/kg} \text{ (throttling)}$$

$$\left. \begin{array}{l} T_5 = -18.5^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} P_5 = 0.14165 \text{ MPa} \\ h_5 = 239.33 \text{ kJ/kg} \end{array}$$

Then the mass flow rate of the refrigerant and the power input becomes

$$\dot{m} = \frac{\dot{V}_1}{v_1} = \frac{0.3/60 \text{ m}^3/\text{s}}{0.14605 \text{ m}^3/\text{kg}} = 0.03423 \text{ kg/s}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_{2s} - h_1)/\eta_C = (0.03423 \text{ kg/s})[(289.20 - 246.36) \text{ kJ/kg}]/(0.78) = \mathbf{1.88 \text{ kW}}$$

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}(h_5 - h_4) = (0.03423 \text{ kg/s})(239.33 - 93.58) \text{ kJ/kg} = \mathbf{4.99 \text{ kW}}$$

(c) The pressure drop and the heat gain in the line between the evaporator and the compressor are

$$\Delta P = P_5 - P_1 = 141.65 - 140 = \mathbf{1.65}$$

and

$$\dot{Q}_{\text{gain}} = \dot{m}(h_1 - h_5) = (0.03423 \text{ kg/s})(246.36 - 239.33) \text{ kJ/kg} = \mathbf{0.241 \text{ kW}}$$

**11-24 EES** Problem 11-23 is reconsidered. The effects of the compressor isentropic efficiency and the compressor inlet volume flow rate on the power input and the rate of refrigeration are to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**11-25** A refrigerator uses refrigerant-134a as the working fluid and operates on the ideal vapor-compression refrigeration cycle. The mass flow rate of the refrigerant, the condenser pressure, and the COP of the refrigerator are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) (b) From the refrigerant-134a tables (Tables A-11 through A-13)

$$\left. \begin{array}{l} P_4 = 120 \text{ kPa} \\ x_4 = 0.30 \end{array} \right\} h_4 = 86.83 \text{ kJ/kg}$$

$$h_3 = h_4$$

$$\left. \begin{array}{l} h_3 = 86.83 \text{ kJ/kg} \\ x_3 = 0 \text{ (sat. liq.)} \end{array} \right\} P_3 = \mathbf{671.8 \text{ kPa}}$$

$$P_2 = P_3$$

$$\left. \begin{array}{l} P_2 = 671.8 \text{ kPa} \\ T_2 = 60^\circ\text{C} \end{array} \right\} h_2 = 298.87 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_1 = P_4 = 120 \text{ kPa} \\ x_1 = 1 \text{ (sat. vap.)} \end{array} \right\} h_1 = 236.97 \text{ kJ/kg}$$

The mass flow rate of the refrigerant is determined from

$$\dot{m} = \frac{\dot{W}_{\text{in}}}{h_2 - h_1} = \frac{0.45 \text{ kW}}{(298.87 - 236.97) \text{ kJ/kg}} = \mathbf{0.00727 \text{ kg/s}}$$

(c) The refrigeration load and the COP are

$$\begin{aligned} \dot{Q}_L &= \dot{m}(h_1 - h_4) \\ &= (0.00727 \text{ kg/s})(236.97 - 86.83) \text{ kJ/kg} \\ &= \mathbf{1.091 \text{ kW}} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{1.091 \text{ kW}}{0.45 \text{ kW}} = \mathbf{2.43}$$

## Selecting the Right Refrigerant

**11-26C** The desirable characteristics of a refrigerant are to have an evaporator pressure which is above the atmospheric pressure, and a condenser pressure which corresponds to a saturation temperature above the temperature of the cooling medium. Other desirable characteristics of a refrigerant include being nontoxic, noncorrosive, nonflammable, chemically stable, having a high enthalpy of vaporization (minimizes the mass flow rate) and, of course, being available at low cost.

**11-27C** The minimum pressure that the refrigerant needs to be compressed to is the saturation pressure of the refrigerant at 30°C, which is **0.771 MPa**. At lower pressures, the refrigerant will have to condense at temperatures lower than the temperature of the surroundings, which cannot happen.

**11-28C** Allowing a temperature difference of 10°C for effective heat transfer, the evaporation temperature of the refrigerant should be -20°C. The saturation pressure corresponding to -20°C is 0.133 MPa. Therefore, the recommended pressure would be 0.12 MPa.

**11-29** A refrigerator that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. Reasonable pressures for the evaporator and the condenser are to be selected.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** Allowing a temperature difference of 10°C for effective heat transfer, the evaporation and condensation temperatures of the refrigerant should be -20°C and 35°C, respectively. The saturation pressures corresponding to these temperatures are 0.133 MPa and 0.888 MPa. Therefore, the recommended evaporator and condenser pressures are **0.133 MPa** and **0.888 MPa**, respectively.

**11-30** A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. Reasonable pressures for the evaporator and the condenser are to be selected.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** Allowing a temperature difference of 10°C for effective heat transfer, the evaporation and condensation temperatures of the refrigerant should be 0°C and 32°C, respectively. The saturation pressures corresponding to these temperatures are 0.293 MPa and 0.816 MPa. Therefore, the recommended evaporator and condenser pressures are **0.293 MPa** and **0.816 MPa**, respectively.

## Heat Pump Systems

**11-31C** A heat pump system is more cost effective in Miami because of the low heating loads and high cooling loads at that location.

**11-32C** A water-source heat pump extracts heat from water instead of air. Water-source heat pumps have higher COPs than the air-source systems because the temperature of water is higher than the temperature of air in winter.

**11-33** An actual heat pump cycle with R-134a as the refrigerant is considered. The isentropic efficiency of the compressor, the rate of heat supplied to the heated room, the COP of the heat pump, and the COP of the heat pump and the rate of heat supplied to the heated room if this heat pump operated on the ideal vapor-compression cycle between the same pressure limits are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The properties of refrigerant-134a are (Tables A-11 through A-13)

$$\begin{aligned} P_2 &= 800 \text{ kPa} \\ T_2 &= 55^\circ\text{C} \end{aligned} \left\} \begin{aligned} h_2 &= 291.76 \text{ kJ/kg} \\ T_3 &= T_{\text{sat}@750 \text{ kPa}} = 29.06^\circ\text{C} \end{aligned} \right.$$

$$\begin{aligned} P_3 &= 750 \text{ kPa} \\ T_3 &= (29.06 - 3)^\circ\text{C} \end{aligned} \left\} \begin{aligned} h_3 &= 87.91 \text{ kJ/kg} \\ h_4 &= h_3 = 87.91 \text{ kJ/kg} \end{aligned} \right.$$

$$T_{\text{sat}@200 \text{ kPa}} = -10.09^\circ\text{C}$$

$$\begin{aligned} P_1 &= 200 \text{ kPa} \\ T_1 &= (-10.09 + 4)^\circ\text{C} \end{aligned} \left\} \begin{aligned} h_1 &= 247.87 \text{ kJ/kg} \\ s_1 &= 0.9506 \text{ kJ/kg} \end{aligned} \right.$$

$$\begin{aligned} P_2 &= 800 \text{ kPa} \\ s_2 &= s_1 \end{aligned} \left\} \begin{aligned} h_{2s} &= 277.26 \end{aligned} \right.$$

The isentropic efficiency of the compressor is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{277.26 - 247.87}{291.76 - 247.87} = \mathbf{0.670}$$

(b) The rate of heat supplied to the room is

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.018 \text{ kg/s})(291.76 - 87.91) \text{ kJ/kg} = \mathbf{3.67 \text{ kW}}$$

(c) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.018 \text{ kg/s})(291.76 - 247.87) \text{ kJ/kg} = 0.790 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{3.67}{0.790} = \mathbf{4.64}$$

(d) The ideal vapor-compression cycle analysis of the cycle is as follows:

$$\begin{aligned} h_1 &= h_{g@200 \text{ kPa}} = 244.46 \text{ kJ/kg} \\ s_1 &= s_{g@200 \text{ kPa}} = 0.9377 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_2 &= 800 \text{ kPa} \\ s_2 &= s_1 \end{aligned} \left\} \begin{aligned} h_2 &= 273.25 \text{ kJ/kg} \end{aligned} \right.$$

$$\begin{aligned} h_3 &= h_{f@800 \text{ kPa}} = 95.47 \text{ kJ/kg} \\ h_4 &= h_3 \end{aligned}$$

$$\text{COP} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{273.25 - 95.47}{273.25 - 244.46} = \mathbf{6.18}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.018 \text{ kg/s})(273.25 - 95.47) \text{ kJ/kg} = \mathbf{3.20 \text{ kW}}$$

**11-34** A heat pump operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP and the rate of heat supplied to the evaporator are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = 280 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 280 \text{ kPa} = 249.72 \text{ kJ/kg} \\ s_1 = s_g @ 280 \text{ kPa} = 0.93210 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 280.00 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1200 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1200 \text{ kPa} = 117.77 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 117.77 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is determined from

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) \longrightarrow \dot{m} = \frac{\dot{W}_{\text{in}}}{h_2 - h_1} = \frac{20 \text{ kJ/s}}{(280.00 - 249.72) \text{ kJ/kg}} = 0.6605 \text{ kg/s}$$

Then the rate of heat supplied to the evaporator is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.6605 \text{ kg/s})(249.72 - 117.77) \text{ kJ/kg} = \mathbf{87.15 \text{ kW}}$$

The COP of the heat pump is determined from its definition,

$$\text{COP}_{\text{HP}} = \frac{q_H}{w_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{280.00 - 117.77}{280.00 - 249.72} = \mathbf{5.36}$$

**11-35** A heat pump operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The effect of compressor irreversibilities on the COP of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In this cycle, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. The compression process is not isentropic. The saturation pressure of refrigerant at  $-1.25^\circ\text{C}$  is 280 kPa. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = 280 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 280 \text{ kPa} = 249.72 \text{ kJ/kg} \\ s_1 = s_g @ 280 \text{ kPa} = 0.93210 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 271.50 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 95.47 \text{ kJ/kg} \quad (\text{throttling})$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 249.72 + \frac{271.50 - 249.72}{0.85} = 275.34 \text{ kJ/kg}$$

The COPs of the heat pump for isentropic and irreversible compression cases are

$$\text{COP}_{\text{HP, ideal}} = \frac{q_H}{w_{\text{in}}} = \frac{h_{2s} - h_3}{h_{2s} - h_1} = \frac{271.50 - 95.47}{271.50 - 249.72} = \mathbf{8.082}$$

$$\text{COP}_{\text{HP, actual}} = \frac{q_H}{w_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{275.34 - 95.47}{275.34 - 249.72} = \mathbf{7.021}$$

The irreversible compressor decreases the COP by **13.1%**.

**11-36** A heat pump operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The effect of superheating at the compressor inlet on the COP of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In this cycle, the compression process is isentropic and leaves the condenser as saturated liquid at the condenser pressure. The refrigerant entering the compressor is superheated by 2°C. The saturation pressure of refrigerant at -1.25°C is 280 kPa. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = 280 \text{ kPa} \\ T_1 = -1.25 + 2 = 1.25^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 251.96 \text{ kJ/kg} \\ s_1 = 0.9403 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 274.04 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 95.47 \text{ kJ/kg} \quad (\text{throttling})$$

The states at the inlet and exit of the compressor when the refrigerant enters the compressor as a saturated vapor are

$$\left. \begin{array}{l} P_1 = 280 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 280 \text{ kPa} = 249.72 \text{ kJ/kg} \\ s_1 = s_g @ 280 \text{ kPa} = 0.93210 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 271.50 \text{ kJ/kg}$$

The COPs of the heat pump for the two cases are

$$\text{COP}_{\text{HP, ideal}} = \frac{q_H}{w_{\text{in}}} = \frac{h_{2s} - h_3}{h_{2s} - h_1} = \frac{271.50 - 95.47}{271.50 - 249.72} = \mathbf{8.082}$$

$$\text{COP}_{\text{HP, actual}} = \frac{q_H}{w_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{274.04 - 95.47}{274.04 - 251.96} = \mathbf{8.087}$$

The effect of superheating on the COP is negligible.

**11-37E** A heat pump operating on the vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The effect of subcooling at the exit of the condenser on the power requirement is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In this cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as subcooled liquid. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_1 = 50 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 50 \text{ psia} = 108.81 \text{ Btu/lbm} \\ s_1 = s_g @ 50 \text{ psia} = 0.22188 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 119.19 \text{ Btu/lbm}$$

$$T_3 = T_{\text{sat}} @ 160 \text{ psia} - 9.5 = 109.5 - 9.5 = 100^\circ\text{F}$$

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ T_3 = 100^\circ\text{F} \end{array} \right\} h_3 \cong h_f @ 100^\circ\text{F} = 45.124 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 45.124 \text{ Btu/lbm} \quad (\text{throttling})$$

The states at the inlet and exit of the expansion valve when the refrigerant is saturated liquid at the condenser exit are

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 160 \text{ psia} = 48.519 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 48.519 \text{ Btu/lbm} \quad (\text{throttling})$$

The mass flow rate of the refrigerant in the ideal case is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{100,000 \text{ Btu/h}}{(108.81 - 45.124) \text{ Btu/lbm}} = 1415.0 \text{ lbm/h}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (1415.0 \text{ lbm/h})(119.19 - 108.81) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{4.305 \text{ kW}}$$

With subcooling, the mass flow rate and the power input are

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{100,000 \text{ Btu/h}}{(108.81 - 45.124) \text{ Btu/lbm}} = 1350.1 \text{ lbm/h}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (1350.1 \text{ lbm/h})(119.19 - 108.81) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{4.107 \text{ kW}}$$

Subcooling decreases the power requirement by 4.6%.

**11-38E** A heat pump operating on the vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The effect of superheating at the compressor inlet on the power requirement is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In this cycle, the compression process is isentropic and leaves the condenser as saturated liquid at the condenser pressure. The refrigerant entering the compressor is superheated by 10°F. The saturation temperature of the refrigerant at 50 psia is 40.23°F. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_1 = 50 \text{ psia} \\ T_1 = 40.23 + 10 = 50.2^\circ\text{F} \end{array} \right\} \begin{array}{l} h_1 = 110.99 \text{ Btu/lbm} \\ s_1 = 0.2262 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 121.71 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 160 \text{ psia} = 48.519 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 48.519 \text{ Btu/lbm} \quad (\text{throttling})$$

The states at the inlet and exit of the compressor when the refrigerant enters the compressor as a saturated vapor are

$$\left. \begin{array}{l} P_1 = 50 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 50 \text{ psia} = 108.81 \text{ Btu/lbm} \\ s_1 = s_g @ 50 \text{ psia} = 0.22188 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 119.19 \text{ Btu/lbm}$$

The mass flow rate of the refrigerant in the ideal case is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{100,000 \text{ Btu/h}}{(119.19 - 48.519) \text{ Btu/lbm}} = 1415.0 \text{ lbm/h}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (1415.0 \text{ lbm/h})(119.19 - 108.81) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{4.305 \text{ kW}}$$

With superheating, the mass flow rate and the power input are

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{100,000 \text{ Btu/h}}{(121.71 - 48.519) \text{ Btu/lbm}} = 1366.3 \text{ lbm/h}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (1366.3 \text{ lbm/h})(121.71 - 110.99) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{4.293 \text{ kW}}$$

Superheating decreases the power requirement slightly.

**11-39** A geothermal heat pump is considered. The degrees of subcooling done on the refrigerant in the condenser, the mass flow rate of the refrigerant, the heating load, the COP of the heat pump, the minimum power input are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) From the refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} T_4 = 20^\circ\text{C} \quad \left. \begin{array}{l} P_4 = 572.1 \text{ kPa} \\ x_4 = 0.23 \end{array} \right\} h_4 = 121.24 \text{ kJ/kg} \\ h_3 = h_4 \\ P_1 = 572.1 \text{ kPa} \quad \left. \begin{array}{l} h_1 = 261.59 \text{ kJ/kg} \\ x_1 = 1 \text{ (sat. vap.)} \end{array} \right\} s_1 = 0.9223 \text{ kJ/kg} \\ P_2 = 1400 \text{ kPa} \quad \left. \begin{array}{l} h_2 = 280.00 \text{ kJ/kg} \\ s_2 = s_1 \end{array} \right\} \end{aligned}$$

From the steam tables (Table A-4)

$$h_{w1} = h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg}$$

$$h_{w2} = h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg}$$

The saturation temperature at the condenser pressure of 1400 kPa and the actual temperature at the condenser outlet are

$$T_{\text{sat @ 1400 kPa}} = 52.40^\circ\text{C}$$

$$\begin{aligned} P_3 = 1400 \text{ kPa} \quad \left. \begin{array}{l} h_3 = 121.24 \text{ kJ} \end{array} \right\} T_3 = 48.59^\circ\text{C} \text{ (from EES)} \end{aligned}$$

Then, the degrees of subcooling is

$$\Delta T_{\text{subcool}} = T_{\text{sat}} - T_3 = 52.40 - 48.59 = \mathbf{3.81^\circ\text{C}}$$

(b) The rate of heat absorbed from the geothermal water in the evaporator is

$$\dot{Q}_L = \dot{m}_w (h_{w1} - h_{w2}) = (0.065 \text{ kg/s})(209.34 - 167.53) \text{ kJ/kg} = 2.718 \text{ kW}$$

This heat is absorbed by the refrigerant in the evaporator

$$\dot{m}_R = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{2.718 \text{ kW}}{(261.59 - 121.24) \text{ kJ/kg}} = \mathbf{0.01936 \text{ kg/s}}$$

(c) The power input to the compressor, the heating load and the COP are

$$\dot{W}_{\text{in}} = \dot{m}_R (h_2 - h_1) + \dot{Q}_{\text{out}} = (0.01936 \text{ kg/s})(280.00 - 261.59) \text{ kJ/kg} = 0.6564 \text{ kW}$$

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = (0.01936 \text{ kg/s})(280.00 - 121.24) \text{ kJ/kg} = \mathbf{3.074 \text{ kW}}$$

$$\text{COP} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{3.074 \text{ kW}}{0.6564 \text{ kW}} = \mathbf{4.68}$$

(d) The reversible COP of the cycle is

$$\text{COP}_{\text{rev}} = \frac{1}{1 - T_L / T_H} = \frac{1}{1 - (25 + 273) / (50 + 273)} = 12.92$$

The corresponding minimum power input is

$$\dot{W}_{\text{in, min}} = \frac{\dot{Q}_H}{\text{COP}_{\text{rev}}} = \frac{3.074 \text{ kW}}{12.92} = \mathbf{0.238 \text{ kW}}$$

## Innovative Refrigeration Systems

**11-40C** Performing the refrigeration in stages is called cascade refrigeration. In cascade refrigeration, two or more refrigeration cycles operate in series. Cascade refrigerators are more complex and expensive, but they have higher COP's, they can incorporate two or more different refrigerants, and they can achieve much lower temperatures.

**11-41C** Cascade refrigeration systems have higher COPs than the ordinary refrigeration systems operating between the same pressure limits.

**11-42C** The saturation pressure of refrigerant-134a at  $-32^{\circ}\text{C}$  is 77 kPa, which is below the atmospheric pressure. In reality a pressure below this value should be used. Therefore, a cascade refrigeration system with a different refrigerant at the bottoming cycle is recommended in this case.

**11-43C** We would favor the two-stage compression refrigeration system with a flash chamber since it is simpler, cheaper, and has better heat transfer characteristics.

**11-44C** Yes, by expanding the refrigerant in stages in several throttling devices.

**11-45C** To take advantage of the cooling effect by throttling from high pressures to low pressures.

**11-46 [Also solved by EES on enclosed CD]** A two-stage compression refrigeration system with refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the rate of heat removed from the refrigerated space, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flash chamber is adiabatic.

**Analysis** (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$\begin{aligned} h_1 &= 239.16 \text{ kJ/kg}, & h_2 &= 265.31 \text{ kJ/kg} \\ h_3 &= 259.30 \text{ kJ/kg}, & & \\ h_5 &= 107.32 \text{ kJ/kg}, & h_6 &= 107.32 \text{ kJ/kg} \\ h_7 &= 73.33 \text{ kJ/kg}, & h_8 &= 73.33 \text{ kJ/kg} \end{aligned}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{107.32 - 73.33}{185.98} = \mathbf{0.1828}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi=0 \text{ (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ (1)h_9 &= x_6 h_3 + (1 - x_6)h_2 \\ h_9 &= (0.1828)(259.30) + (1 - 0.1828)(265.31) = 264.21 \text{ kJ/kg} \end{aligned}$$

also,

$$\left. \begin{aligned} P_4 &= 1 \text{ MPa} \\ s_4 &= s_9 = 0.94083 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} h_4 = 278.97 \text{ kJ/kg}$$

Then the rate of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$\begin{aligned} \dot{m}_B &= (1 - x_6)\dot{m}_A = (1 - 0.1828)(0.25 \text{ kg/s}) = 0.2043 \text{ kg/s} \\ \dot{Q}_L &= \dot{m}_B(h_1 - h_8) = (0.2043 \text{ kg/s})(239.16 - 73.33) \text{ kJ/kg} = \mathbf{33.88 \text{ kW}} \\ \dot{W}_{\text{in}} &= \dot{W}_{\text{compI, in}} + \dot{W}_{\text{compII, in}} = \dot{m}_A(h_4 - h_9) + \dot{m}_B(h_2 - h_1) \\ &= (0.25 \text{ kg/s})(278.97 - 264.21) \text{ kJ/kg} + (0.2043 \text{ kg/s})(265.31 - 239.16) \text{ kJ/kg} \\ &= 9.03 \text{ kW} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{33.88 \text{ kW}}{9.03 \text{ kW}} = \mathbf{3.75}$$

**11-47 EES** Problem 11-46 is reconsidered. The effects of the various refrigerants in EES data bank for compressor efficiencies of 80, 90, and 100 percent is to be investigated.

**Analysis** The problem is solved using EES, and the results are tabulated and plotted below.

**11-48 [Also solved by EES on enclosed CD]** A two-stage compression refrigeration system with refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the rate of heat removed from the refrigerated space, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flash chamber is adiabatic.

**Analysis** (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$h_1 = 239.16 \text{ kJ/kg}, \quad h_2 = 255.90 \text{ kJ/kg}$$

$$h_3 = 251.88 \text{ kJ/kg},$$

$$h_5 = 107.32 \text{ kJ/kg}, \quad h_6 = 107.32 \text{ kJ/kg}$$

$$h_7 = 55.16 \text{ kJ/kg}, \quad h_8 = 55.16 \text{ kJ/kg}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{107.32 - 55.16}{196.71} = \mathbf{0.2651}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi=0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i$$

$$(1)h_9 = x_6 h_3 + (1 - x_6)h_2$$

$$h_9 = (0.2651)(251.88) + (1 - 0.2651)(255.90) = 254.84 \text{ kJ/kg}$$

and

$$\left. \begin{array}{l} P_9 = 0.32 \text{ MPa} \\ h_9 = 254.84 \text{ kJ/kg} \end{array} \right\} s_9 = 0.94074 \text{ kJ/kg} \cdot \text{K}$$

$$\text{also, } \left. \begin{array}{l} P_4 = 1 \text{ MPa} \\ s_4 = s_9 = 0.94074 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_4 = 278.94 \text{ kJ/kg}$$

Then the rate of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$\dot{m}_B = (1 - x_6)\dot{m}_A = (1 - 0.2651)(0.25 \text{ kg/s}) = 0.1837 \text{ kg/s}$$

$$\dot{Q}_L = \dot{m}_B(h_1 - h_8) = (0.1837 \text{ kg/s})(239.16 - 55.16) \text{ kJ/kg} = \mathbf{33.80 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{W}_{\text{compI, in}} + \dot{W}_{\text{compII, in}} = \dot{m}_A(h_4 - h_9) + \dot{m}_B(h_2 - h_1) \\ &= (0.25 \text{ kg/s})(278.94 - 254.84) \text{ kJ/kg} + (0.1837 \text{ kg/s})(255.90 - 239.16) \text{ kJ/kg} \\ &= \mathbf{9.10 \text{ kW}} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{33.80 \text{ kW}}{9.10 \text{ kW}} = \mathbf{3.71}$$

**11-49** A two-stage cascade refrigeration cycle is considered. The mass flow rate of the refrigerant through the upper cycle, the rate of heat removal from the refrigerated space, and the COP of the refrigerator are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The properties are to be obtained from the refrigerant tables (Tables A-11 through A-13):

$$h_1 = h_g @ 200 \text{ kPa} = 244.46 \text{ kJ/kg}$$

$$s_1 = s_g @ 200 \text{ kPa} = 0.9377 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 263.30 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{263.30 - 244.46}{h_2 - 244.46} \longrightarrow h_2 = 268.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 500 \text{ kPa} = 73.33 \text{ kJ/kg}$$

$$h_4 = h_3 = 73.33 \text{ kJ/kg}$$

$$h_5 = h_g @ 400 \text{ kPa} = 255.55 \text{ kJ/kg}$$

$$s_5 = s_g @ 400 \text{ kPa} = 0.9269 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_6 = 1200 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} h_{6s} = 278.33 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5}$$

$$0.80 = \frac{278.33 - 255.55}{h_6 - 255.55} \longrightarrow h_6 = 284.02 \text{ kJ/kg}$$

$$h_7 = h_f @ 1200 \text{ kPa} = 117.77 \text{ kJ/kg}$$

$$h_8 = h_7 = 117.77 \text{ kJ/kg}$$

The mass flow rate of the refrigerant through the upper cycle is determined from an energy balance on the heat exchanger

$$\dot{m}_A (h_5 - h_8) = \dot{m}_B (h_2 - h_3)$$

$$\dot{m}_A (255.55 - 117.77) \text{ kJ/kg} = (0.15 \text{ kg/s})(268.01 - 73.33) \text{ kJ/kg} \longrightarrow \dot{m}_A = \mathbf{0.212 \text{ kg/s}}$$

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}_B (h_1 - h_4) = (0.15 \text{ kg/s})(244.46 - 73.33) \text{ kJ/kg} = \mathbf{25.67 \text{ kW}}$$

(c) The power input and the COP are

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_A (h_6 - h_5) + \dot{m}_B (h_2 - h_1) \\ &= (0.15 \text{ kg/s})(284.02 - 255.55) \text{ kJ/kg} + (0.212 \text{ kg/s})(268.01 - 244.46) \text{ kJ/kg} = 9.566 \text{ kW} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{25.67}{9.566} = \mathbf{2.68}$$

**11-50** A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The cooling rate of the high-temperature evaporator, the power required by the compressor, and the COP of the system are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$h_4 = h_6 \cong h_3 = 95.47 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 0^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 0^\circ\text{C} = 250.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = -26.4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ -26.4^\circ\text{C} = 234.44 \text{ kJ/kg}$$

The mass flow rate through the low-temperature evaporator is found by

$$\dot{Q}_L = \dot{m}_2 (h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_L}{h_7 - h_6} = \frac{8 \text{ kJ/s}}{(234.44 - 95.47) \text{ kJ/kg}} = 0.05757 \text{ kg/s}$$

The mass flow rate through the warmer evaporator is then

$$\dot{m}_1 = \dot{m} - \dot{m}_2 = 0.1 - 0.05757 = 0.04243 \text{ kg/s}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = \dot{m} h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}} = \frac{(0.04243)(250.45) + (0.05757)(234.44)}{0.1} = 241.23 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = P_{\text{sat @ } -26.4^\circ\text{C}} \cong 100 \text{ kPa} \\ h_1 = 241.23 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9789 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 286.26 \text{ kJ/kg}$$

The cooling rate of the high-temperature evaporator is

$$\dot{Q}_L = \dot{m}_1(h_5 - h_4) = (0.04243 \text{ kg/s})(250.45 - 95.47) \text{ kJ/kg} = \mathbf{6.58 \text{ kW}}$$

The power input to the compressor is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.1 \text{ kg/s})(286.26 - 241.23) \text{ kJ/kg} = \mathbf{4.50 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(8 + 6.58) \text{ kW}}{4.50 \text{ kW}} = \mathbf{3.24}$$

**11-51E** A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The power required by the compressor and the COP of the system are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 140 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 140 \text{ psia} = 45.304 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 45.304 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 30 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 30 \text{ psia} = 105.32 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_7 = 15 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ 15 \text{ psia} = 100.99 \text{ Btu/lbm}$$

The mass flow rates through the high-temperature and low-temperature evaporators are found by

$$\dot{Q}_{L,1} = \dot{m}_1(h_5 - h_4) \longrightarrow \dot{m}_1 = \frac{\dot{Q}_{L,1}}{h_5 - h_4} = \frac{3000 \text{ Btu/h}}{(105.32 - 45.304) \text{ Btu/lbm}} = 49.99 \text{ lbm/h}$$

$$\dot{Q}_{L,2} = \dot{m}_2(h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_{L,2}}{h_7 - h_6} = \frac{10,000 \text{ Btu/h}}{(100.99 - 45.304) \text{ Btu/lbm}} = 179.58 \text{ lbm/h}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = (\dot{m}_1 + \dot{m}_2) h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}_1 + \dot{m}_2} = \frac{(49.99)(105.32) + (179.58)(100.99)}{49.99 + 179.58} = 101.93 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = 15 \text{ psia} \\ h_1 = 101.93 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2293 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 140 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 122.24 \text{ Btu/lbm}$$

The power input to the compressor is

$$\dot{W}_{in} = (\dot{m}_1 + \dot{m}_2)(h_2 - h_1) = (49.99 + 179.58) \text{ lbm/h} (122.24 - 101.93) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{1.366 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{(10,000 + 3000) \text{ Btu/h}}{1.366 \text{ kW}} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{2.79}$$

**11-52E** A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The power required by the compressor and the COP of the system are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 140 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 140 \text{ psia} = 45.304 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 45.304 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 60 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 60 \text{ psia} = 110.11 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_7 = 15 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ 15 \text{ psia} = 100.99 \text{ Btu/lbm}$$

The mass flow rates through the high-temperature and low-temperature evaporators are found by

$$\dot{Q}_{L,1} = \dot{m}_1(h_5 - h_4) \longrightarrow \dot{m}_1 = \frac{\dot{Q}_{L,1}}{h_5 - h_4} = \frac{48,000 \text{ Btu/h}}{(110.11 - 45.304) \text{ Btu/lbm}} = 740.7 \text{ lbm/h}$$

$$\dot{Q}_{L,2} = \dot{m}_2(h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_{L,2}}{h_7 - h_6} = \frac{10,000 \text{ Btu/h}}{(100.99 - 45.304) \text{ Btu/lbm}} = 179.6 \text{ lbm/h}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = (\dot{m}_1 + \dot{m}_2) h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}_1 + \dot{m}_2} = \frac{(740.7)(110.11) + (179.58)(100.99)}{740.7 + 179.58} = 108.33 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = 15 \text{ psia} \\ h_1 = 108.33 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2430 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 140 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 130.45 \text{ Btu/lbm}$$

The power input to the compressor is

$$\dot{W}_{in} = (\dot{m}_1 + \dot{m}_2)(h_2 - h_1) = (740.7 + 179.6) \text{ lbm/h}(130.45 - 108.33) \text{ Btu/lbm} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{5.966 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{(48,000 + 10,000) \text{ Btu/h}}{5.966 \text{ kW}} \left( \frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{2.85}$$

**11-53** A two-stage compression refrigeration system with a separation unit is considered. The mass flow rate through the two compressors, the power used by the compressors, and the system's COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = -10.1^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -10.1^\circ\text{C} = 244.46 \text{ kJ/kg} \\ s_1 = s_g @ -10.1^\circ\text{C} = 0.93773 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 273.24 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 95.47 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = -10.1^\circ\text{C} \\ \text{sat. liquid} \end{array} \right\} h_5 = h_f @ -10.1^\circ\text{C} = 38.43 \text{ kJ/kg}$$

$$h_6 \cong h_5 = 38.43 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_7 = -40^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_7 = h_g @ -40^\circ\text{C} = 225.86 \text{ kJ/kg} \\ s_7 = s_g @ -40^\circ\text{C} = 0.96866 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_8 = P_{\text{sat}} @ -10.1^\circ\text{C} = 200 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_8 = 252.74 \text{ kJ/kg}$$

The mass flow rate through the evaporator is determined from

$$\dot{Q}_L = \dot{m}_6(h_7 - h_6) \longrightarrow \dot{m}_6 = \frac{\dot{Q}_L}{h_7 - h_6} = \frac{30 \text{ kJ/s}}{(225.86 - 38.43) \text{ kJ/kg}} = \mathbf{0.1601 \text{ kg/s}}$$

An energy balance on the separator gives

$$\dot{m}_6(h_8 - h_5) = \dot{m}_2(h_1 - h_4) \longrightarrow \dot{m}_2 = \dot{m}_6 \frac{h_8 - h_5}{h_1 - h_4} = (0.1601) \frac{252.74 - 38.43}{244.46 - 95.47} = \mathbf{0.2303 \text{ kg/s}}$$

The total power input to the compressors is

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_6(h_8 - h_7) + \dot{m}_2(h_2 - h_1) \\ &= (0.1601 \text{ kg/s})(252.74 - 225.86) \text{ kJ/kg} + (0.2303 \text{ kg/s})(273.24 - 244.46) \text{ kJ/kg} \\ &= \mathbf{10.93 \text{ kW}} \end{aligned}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{30 \text{ kW}}{10.93 \text{ kW}} = \mathbf{2.74}$$

**11-54E** A two-stage compression refrigeration system with a separation unit is considered. The cooling load and the system's COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_1 = 120 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 120 \text{ psia} = 115.16 \text{ Btu/lbm} \\ s_1 = s_g @ 120 \text{ psia} = 0.21924 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_2 = 300 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 123.06 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 300 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 300 \text{ psia} = 66.339 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 66.339 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 120 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_5 = h_f @ 120 \text{ psia} = 41.787 \text{ Btu/lbm}$$

$$h_6 \cong h_5 = 41.787 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_7 = 60 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_7 = h_g @ 60 \text{ psia} = 110.11 \text{ Btu/lbm} \\ s_7 = s_g @ 60 \text{ psia} = 0.22127 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_8 = 120 \text{ psia} \\ s_8 = s_7 \end{array} \right\} h_8 = 116.28 \text{ Btu/lbm}$$

An energy balance on the separator gives

$$\dot{m}_6(h_8 - h_5) = \dot{m}_2(h_1 - h_4) \longrightarrow \dot{m}_2 = \dot{m}_6 \frac{h_8 - h_5}{h_1 - h_4} = \dot{m}_6 \frac{116.28 - 41.787}{115.16 - 66.339} = 1.5258 \dot{m}_6$$

The total power input to the compressors is given by

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_6(h_8 - h_7) + \dot{m}_2(h_2 - h_1) \\ &= \dot{m}_6(h_8 - h_7) + 1.5258 \dot{m}_6(h_2 - h_1) \end{aligned}$$

Solving for  $\dot{m}_6$ ,

$$\dot{m}_6 = \frac{\dot{W}_{\text{in}}}{(h_8 - h_7) + 1.5258(h_2 - h_1)} = \frac{(25 \times 3412.14) \text{ Btu/h}}{(116.28 - 110.11) + 1.5258(123.06 - 115.16) \text{ Btu/lbm}} = 4681 \text{ lbm/h}$$

The cooling effect produced by this system is then

$$\dot{Q}_L = \dot{m}_6(h_7 - h_6) = (4681 \text{ lbm/h})(110.11 - 41.787) \text{ Btu/lbm} = \mathbf{319,800 \text{ Btu/h}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(319,800/3412.14) \text{ kW}}{25 \text{ kW}} = \mathbf{3.75}$$

**11-55** A two-stage cascade refrigeration system is considered. Each stage operates on the ideal vapor-compression cycle with upper cycle using water and lower cycle using refrigerant-134a as the working fluids. The mass flow rate of R-134a and water in their respective cycles and the overall COP of this system are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The heat exchanger is adiabatic.

**Analysis** From the water and refrigerant tables (Tables A-4, A-5, A-6, A-11, A-12, and A-13),

$$\begin{aligned}
 & \left. \begin{array}{l} T_1 = 5^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 5^\circ\text{C} = 2510.1 \text{ kJ/kg} \\ s_1 = s_g @ 5^\circ\text{C} = 9.0249 \text{ kJ/kg} \cdot \text{K} \end{array} \\
 & \left. \begin{array}{l} P_2 = 1.6 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 5083.4 \text{ kJ/kg} \\
 & \left. \begin{array}{l} P_3 = 1.6 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1.6 \text{ MPa} = 858.44 \text{ kJ/kg} \\
 & h_4 \cong h_3 = 858.44 \text{ kJ/kg} \quad (\text{throttling}) \\
 & \left. \begin{array}{l} T_5 = -40^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_5 = h_g @ -40^\circ\text{C} = 225.86 \text{ kJ/kg} \\ s_5 = s_g @ -40^\circ\text{C} = 0.96866 \text{ kJ/kg} \cdot \text{K} \end{array} \\
 & \left. \begin{array}{l} P_6 = 400 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} h_6 = 267.59 \text{ kJ/kg} \\
 & \left. \begin{array}{l} P_7 = 400 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_7 = h_f @ 400 \text{ kPa} = 63.94 \text{ kJ/kg} \\
 & h_8 \cong h_7 = 63.94 \text{ kJ/kg} \quad (\text{throttling})
 \end{aligned}$$

The mass flow rate of R-134a is determined from

$$\dot{Q}_L = \dot{m}_R (h_5 - h_8) \longrightarrow \dot{m}_R = \frac{\dot{Q}_L}{h_5 - h_8} = \frac{20 \text{ kJ/s}}{(225.86 - 63.94) \text{ kJ/kg}} = \mathbf{0.1235 \text{ kg/s}}$$

An energy balance on the heat exchanger gives the mass flow rate of water

$$\begin{aligned}
 \dot{m}_R (h_6 - h_7) &= \dot{m}_w (h_1 - h_4) \\
 \longrightarrow \dot{m}_w &= \dot{m}_R \frac{h_6 - h_7}{h_1 - h_4} = (0.1235 \text{ kg/s}) \frac{267.59 - 63.94}{2510.1 - 858.44} = \mathbf{0.01523 \text{ kg/s}}
 \end{aligned}$$

The total power input to the compressors is

$$\begin{aligned}
 \dot{W}_{\text{in}} &= \dot{m}_R (h_6 - h_5) + \dot{m}_w (h_2 - h_1) \\
 &= (0.1235 \text{ kg/s})(267.59 - 225.86) \text{ kJ/kg} + (0.01523 \text{ kg/s})(5083.4 - 2510.1) \text{ kJ/kg} \\
 &= \mathbf{44.35 \text{ kJ/s}}
 \end{aligned}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{20 \text{ kJ/s}}{44.35 \text{ kJ/s}} = \mathbf{0.451}$$

**11-56** A two-stage vapor-compression refrigeration system with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Prob. 11-55 and the water and refrigerant tables (Tables A-4, A-5, A-6, A-11, A-12, and A-13),

$$\begin{aligned} s_1 &= s_2 = 9.0249 \text{ kJ/kg} \cdot \text{K} \\ s_3 &= 2.3435 \text{ kJ/kg} \cdot \text{K} \\ s_4 &= 3.0869 \text{ kJ/kg} \cdot \text{K} \\ s_5 &= s_6 = 0.96866 \text{ kJ/kg} \cdot \text{K} \\ s_7 &= 0.24757 \text{ kJ/kg} \cdot \text{K} \\ s_8 &= 0.27423 \text{ kJ/kg} \cdot \text{K} \\ \dot{m}_R &= 0.1235 \text{ kg/s} \\ \dot{m}_w &= 0.01751 \text{ kg/s} \\ q_L &= h_5 - h_8 = 161.92 \text{ kJ/kg} \\ q_H &= h_2 - h_3 = 4225.0 \text{ kJ/kg} \\ T_L &= -30^\circ\text{C} = 243 \text{ K} \\ T_H &= 30^\circ\text{C} = 303 \text{ K} \\ T_0 &= 30^\circ\text{C} = 303 \text{ K} \end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} \dot{X}_{\text{destroyed}, 23} &= \dot{m}_w T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) \\ &= (0.01751)(303 \text{ K}) \left( 2.3435 - 9.0249 + \frac{4225.0}{303} \right) = 38.53 \text{ kJ/s} \end{aligned}$$

$$\dot{X}_{\text{destroyed}, 34} = \dot{m}_w T_0 (s_4 - s_3) = (0.01751)(303)(3.0869 - 2.3435) = 3.94 \text{ kJ/s}$$

$$\dot{X}_{\text{destroyed}, 78} = \dot{m}_R T_0 (s_8 - s_7) = (0.1235)(303)(0.27423 - 0.24757) = 1.00 \text{ kJ/s}$$

$$\begin{aligned} \dot{X}_{\text{destroyed}, 85} &= \dot{m}_R T_0 \left( s_5 - s_8 - \frac{q_L}{T_L} \right) \\ &= (0.1235)(303) \left( 0.96866 - 0.27423 - \frac{161.92}{243} \right) = 1.05 \text{ kJ/s} \end{aligned}$$

$$\begin{aligned} \dot{X}_{\text{destroyed, heat exch}} &= T_0 [\dot{m}_w (s_1 - s_4) + \dot{m}_R (s_7 - s_6)] \\ &= (303) [(0.01751)(9.0249 - 3.0869) + (0.1235)(0.24757 - 0.96866)] = 4.52 \text{ kJ/s} \end{aligned}$$

For isentropic processes, the exergy destruction is zero:

$$\dot{X}_{\text{destroyed}, 12} = 0$$

$$\dot{X}_{\text{destroyed}, 56} = 0$$

Note that heat is absorbed from a reservoir at  $-30^\circ\text{C}$  (243 K) and rejected to a reservoir at  $30^\circ\text{C}$  (303 K), which is also taken as the dead state temperature. Alternatively, one may use the standard  $25^\circ\text{C}$  (298 K) as the dead state temperature, and perform the calculations accordingly. The greatest exergy destruction occurs in the condenser.

## Gas Refrigeration Cycles

**11-57C** The ideal gas refrigeration cycle is identical to the Brayton cycle, except it operates in the reversed direction.

**11-58C** The reversed Stirling cycle is identical to the Stirling cycle, except it operates in the reversed direction. Remembering that the Stirling cycle is a totally reversible cycle, the reversed Stirling cycle is also totally reversible, and thus its COP is

$$\text{COP}_{\text{R, Stirling}} = \frac{1}{T_H / T_L - 1}$$

**11-59C** In the ideal gas refrigeration cycle, the heat absorption and the heat rejection processes occur at constant pressure instead of at constant temperature.

**11-60C** In aircraft cooling, the atmospheric air is compressed by a compressor, cooled by the surrounding air, and expanded in a turbine. The cool air leaving the turbine is then directly routed to the cabin.

**11-61C** No; because  $h = h(T)$  for ideal gases, and the temperature of air will not drop during a throttling ( $h_1 = h_2$ ) process.

**11-62C** By regeneration.

**11-63 [Also solved by EES on enclosed CD]** An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

**Analysis** (a) We assume both the turbine and the compressor to be isentropic, the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 285 \text{ K} \longrightarrow \begin{aligned} h_1 &= 285.14 \text{ kJ/kg} \\ P_{r_1} &= 1.1584 \end{aligned}$$

$$T_3 = 320 \text{ K} \longrightarrow \begin{aligned} h_3 &= 320.29 \text{ kJ/kg} \\ P_{r_3} &= 1.7375 \end{aligned}$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left( \frac{250}{50} \right) (1.1584) = 5.792 \longrightarrow \begin{aligned} T_2 &= 450.4 \text{ K} \\ h_2 &= 452.17 \text{ kJ/kg} \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left( \frac{50}{250} \right) (1.7375) = 0.3475 \longrightarrow \begin{aligned} T_4 &= 201.8 \text{ K} \\ h_4 &= 201.76 \text{ kJ/kg} \end{aligned}$$

Then the rate of refrigeration is

$$\dot{Q}_{\text{refrig}} = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.08 \text{ kg/s})(285.14 - 201.76) \text{ kJ/kg} = \mathbf{6.67 \text{ kW}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net, in}} = \dot{W}_{\text{comp, in}} - \dot{W}_{\text{turb, out}}$$

where

$$\dot{W}_{\text{comp, in}} = \dot{m}(h_2 - h_1) = (0.08 \text{ kg/s})(452.17 - 285.14) \text{ kJ/kg} = 13.36 \text{ kW}$$

$$\dot{W}_{\text{turb, out}} = \dot{m}(h_3 - h_4) = (0.08 \text{ kg/s})(320.29 - 201.76) \text{ kJ/kg} = 9.48 \text{ kW}$$

Thus,

$$\dot{W}_{\text{net, in}} = 13.36 - 9.48 = \mathbf{3.88 \text{ kW}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{6.67 \text{ kW}}{3.88 \text{ kW}} = \mathbf{1.72}$$

**11-64 EES** Problem 11-63 is reconsidered. The effects of compressor and turbine isentropic efficiencies on the rate of refrigeration, the net power input, and the COP are to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**"Input data"**

T[1] = 12 [C]  
P[1] = 50 [kPa]  
T[3] = 47 [C]

**11-65 [Also solved by EES on enclosed CD]** An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

**Analysis** (a) We assume the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 285 \text{ K} \longrightarrow \begin{aligned} h_1 &= 285.14 \text{ kJ/kg} \\ P_{r_1} &= 1.1584 \end{aligned}$$

$$T_3 = 320 \text{ K} \longrightarrow \begin{aligned} h_3 &= 320.29 \text{ kJ/kg} \\ P_{r_3} &= 1.7375 \end{aligned}$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left( \frac{250}{50} \right) (1.1584) = 5.792 \longrightarrow \begin{aligned} T_{2s} &= 450.4 \text{ K} \\ h_{2s} &= 452.17 \text{ kJ/kg} \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left( \frac{50}{250} \right) (1.7375) = 0.3475 \longrightarrow \begin{aligned} T_{4s} &= 201.8 \text{ K} \\ h_{4s} &= 201.76 \text{ kJ/kg} \end{aligned}$$

Also,

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} &\longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) \\ &= 320.29 - (0.85)(320.29 - 201.76) \\ &= 219.54 \text{ kJ/kg} \end{aligned}$$

Then the rate of refrigeration is

$$\dot{Q}_{\text{refrig}} = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.08 \text{ kg/s})(285.14 - 219.54) \text{ kJ/kg} = \mathbf{5.25 \text{ kW}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net, in}} = \dot{W}_{\text{comp, in}} - \dot{W}_{\text{turb, out}}$$

where

$$\begin{aligned} \dot{W}_{\text{comp, in}} &= \dot{m}(h_2 - h_1) = \dot{m}(h_{2s} - h_1) / \eta_C \\ &= (0.08 \text{ kg/s})[(452.17 - 285.14) \text{ kJ/kg}] / (0.80) = 16.70 \text{ kW} \end{aligned}$$

$$\dot{W}_{\text{turb, out}} = \dot{m}(h_3 - h_4) = (0.08 \text{ kg/s})(320.29 - 219.54) \text{ kJ/kg} = 8.06 \text{ kW}$$

Thus,

$$\dot{W}_{\text{net, in}} = 16.70 - 8.06 = \mathbf{8.64 \text{ kW}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{5.25 \text{ kW}}{8.64 \text{ kW}} = \mathbf{0.61}$$

**11-66** A gas refrigeration cycle with helium as the working fluid is considered. The minimum temperature in the cycle, the COP, and the mass flow rate of the helium are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Helium is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of helium are  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.667$  (Table A-2).

**Analysis** (a) From the isentropic relations,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (263\text{K})(3)^{0.667/1.667} = 408.2\text{K}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (323\text{K}) \left( \frac{1}{3} \right)^{0.667/1.667} = 208.1\text{K}$$

and

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta_T (T_3 - T_{4s}) = 323 - (0.80)(323 - 208.1) = 231.1\text{ K} = T_{\min}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1)/\eta_C = 263 + (408.2 - 263)/(0.80) = 444.5\text{ K}$$

(b) The COP of this gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{263 - 231.1}{(444.5 - 263) - (323 - 231.1)} = 0.356 \end{aligned}$$

(c) The mass flow rate of helium is determined from

$$\dot{m} = \frac{\dot{Q}_{\text{refrig}}}{q_L} = \frac{\dot{Q}_{\text{refrig}}}{h_1 - h_4} = \frac{\dot{Q}_{\text{refrig}}}{c_p (T_1 - T_4)} = \frac{18 \text{ kJ/s}}{(5.1926 \text{ kJ/kg}\cdot\text{K})(263 - 231.1)\text{K}} = 0.109 \text{ kg/s}$$

**11-67** A regenerative gas refrigeration cycle using air as the working fluid is considered. The effectiveness of the regenerator, the rate of heat removal from the refrigerated space, the COP of the cycle, and the refrigeration load and the COP if this system operated on the simple gas refrigeration cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2).

**Analysis** (a) From the isentropic relations,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (273.2 \text{ K})(5)^{0.4/1.4} = 432.4 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.80 = \frac{432.4 - 273.2}{T_2 - 273.2} \rightarrow T_2 = 472.5 \text{ K}$$

The temperature at state 4 can be determined by solving the following two equations simultaneously:

$$T_{5s} = T_4 \left( \frac{P_5}{P_4} \right)^{(k-1)/k} = T_4 \left( \frac{1}{5} \right)^{0.4/1.4}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \rightarrow 0.85 = \frac{T_4 - 193.2}{T_4 - T_{5s}}$$

Using EES, we obtain  $T_4 = 281.3 \text{ K}$ .

An energy balance on the regenerator may be written as

$$\dot{m}c_p(T_3 - T_4) = \dot{m}c_p(T_1 - T_6) \rightarrow T_3 - T_4 = T_1 - T_6$$

or,

$$T_6 = T_1 - T_3 + T_4 = 273.2 - 308.2 + 281.3 = 246.3 \text{ K}$$

The effectiveness of the regenerator is

$$\varepsilon_{\text{regen}} = \frac{h_3 - h_4}{h_3 - h_6} = \frac{T_3 - T_4}{T_3 - T_6} = \frac{308.2 - 281.3}{308.2 - 246.3} = \mathbf{0.434}$$

(b) The refrigeration load is

$$\dot{Q}_L = \dot{m}c_p(T_6 - T_5) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(246.3 - 193.2) \text{ K} = \mathbf{21.36 \text{ kW}}$$

(c) The turbine and compressor powers and the COP of the cycle are

$$\dot{W}_{C,\text{in}} = \dot{m}c_p(T_2 - T_1) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(472.5 - 273.2) \text{ K} = 80.13 \text{ kW}$$

$$\dot{W}_{T,\text{out}} = \dot{m}c_p(T_4 - T_5) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(281.3 - 193.2) \text{ K} = 35.43 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{\dot{Q}_L}{\dot{W}_{C,\text{in}} - \dot{W}_{T,\text{out}}} = \frac{21.36}{80.13 - 35.43} = \mathbf{0.478}$$

(d) The simple gas refrigeration cycle analysis is as follows:

$$T_{4s} = T_3 \left( \frac{1}{r} \right)^{(k-1)/k} = (308.2 \text{ K}) \left( \frac{1}{5} \right)^{0.4/1.4} = 194.6 \text{ K}$$

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}} \rightarrow 0.85 = \frac{308.2 - T_4}{308.2 - 194.6} \rightarrow T_4 = 211.6 \text{ K}$$

$$\begin{aligned} \dot{Q}_L &= \dot{m} c_p (T_1 - T_4) \\ &= (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(273.2 - 211.6) \text{ kJ/kg} \\ &= \mathbf{24.74 \text{ kW}} \end{aligned}$$

$$\begin{aligned} \dot{W}_{\text{net,in}} &= \dot{m} c_p (T_2 - T_1) - \dot{m} c_p (T_3 - T_4) \\ &= (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})[(472.5 - 273.2) - (308.2 - 211.6) \text{ kJ/kg}] \\ &= 41.32 \text{ kW} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{24.74}{41.32} = \mathbf{0.599}$$

**11-68E** An ideal gas refrigeration cycle with air as the working fluid has a compression ratio of 4. The COP of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 0.240$  Btu/lbm·R and  $k = 1.4$  (Table A-2Ea).

**Analysis** From the isentropic relations,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (450 \text{ R})(4)^{0.4/1.4} = 668.7 \text{ R}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (560 \text{ R}) \left( \frac{1}{4} \right)^{0.4/1.4} = 376.8 \text{ R}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{450 - 376.8}{(668.7 - 450) - (560 - 376.8)} = \mathbf{2.06} \end{aligned}$$

**11-69E** An gas refrigeration cycle with air as the working fluid has a compression ratio of 4. The COP of the cycle is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** From the isentropic relations,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (450 \text{ R})(4)^{0.4/1.4} = 668.7 \text{ R}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (560 \text{ R}) \left( \frac{6 \text{ psia}}{19 \text{ psia}} \right)^{0.4/1.4} = 402.9 \text{ R}$$

and

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta_T (T_3 - T_{4s}) = 560 - (0.94)(560 - 402.9) = 412.3 \text{ R}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 450 + (668.7 - 450) / (0.87) = 701.4 \text{ R}$$

The COP of this gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{450 - 412.3}{(701.4 - 450) - (560 - 412.3)} = \mathbf{0.364} \end{aligned}$$

**11-70** An ideal gas refrigeration cycle with air as the working fluid provides 15 kW of cooling. The mass flow rate of air and the rates of heat addition and rejection are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** From the isentropic relations,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (293 \text{ K}) \left( \frac{500 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 464.1 \text{ K}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (303 \text{ K}) \left( \frac{100 \text{ kPa}}{500 \text{ kPa}} \right)^{0.4/1.4} = 191.3 \text{ K}$$

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_4) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_4)} = \frac{15 \text{ kJ/s}}{(1.005 \text{ kJ/kg} \cdot \text{K})(293 - 191.3) \text{ K}} = \mathbf{0.1468 \text{ kg/s}}$$

The rate of heat addition to the cycle is the same as the rate of cooling,

$$\dot{Q}_{\text{in}} = \dot{Q}_{\text{Refrig}} = \mathbf{15 \text{ kW}}$$

The rate of heat rejection from the cycle is

$$\dot{Q}_H = \dot{m} c_p (T_2 - T_3) = (0.1468 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(464.1 - 303) \text{ K} = \mathbf{23.8 \text{ kW}}$$

**11-71** An ideal gas refrigeration cycle with air as the working fluid is considered. The minimum pressure ratio for this system to operate properly is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** An energy balance on process 4-1 gives

$$q_{\text{Refrig}} = c_p (T_1 - T_4)$$

$$T_4 = T_1 - \frac{q_{\text{Refrig}}}{c_p} = 268 \text{ K} - \frac{20 \text{ kJ/kg}}{1.005 \text{ kJ/kg} \cdot \text{K}} = 248.1 \text{ K}$$

The minimum temperature at the turbine inlet would be the same as that to which the heat is rejected. That is,

$$T_3 = 293 \text{ K}$$

Then the minimum pressure ratio is determined from the isentropic relation to be

$$\frac{P_3}{P_4} = \left( \frac{T_3}{T_4} \right)^{k/(k-1)} = \left( \frac{293 \text{ K}}{248.1 \text{ K}} \right)^{1.4/0.4} = \mathbf{1.79}$$

**11-72** An ideal gas refrigeration cycle with two stages of compression with intercooling using air as the working fluid is considered. The COP of this system and the mass flow rate of air are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** From the isentropic relations,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (255 \text{ K})(4)^{0.4/1.4} = 378.9 \text{ K}$$

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (283 \text{ K})(4)^{0.4/1.4} = 420.5 \text{ K}$$

$$T_6 = T_5 \left( \frac{P_6}{P_5} \right)^{(k-1)/k} = (283 \text{ K}) \left( \frac{1}{16} \right)^{0.4/1.4} = 128.2 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_6}{(h_2 - h_1) + (h_4 - h_3) - (h_5 - h_6)} \\ &= \frac{T_1 - T_6}{(T_2 - T_1) + (T_4 - T_3) - (T_5 - T_6)} \\ &= \frac{255 - 128.2}{(378.9 - 255) + (420.5 - 283) - (283 - 128.2)} = \mathbf{1.19} \end{aligned}$$

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_6) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_6)} = \frac{(75,000 / 3600) \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot\text{K})(255 - 128.2) \text{ K}} = \mathbf{0.163 \text{ kg/s}}$$

**11-73** A gas refrigeration cycle with two stages of compression with intercooling using air as the working fluid is considered. The COP of this system and the mass flow rate of air are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** From the isentropic relations,

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (255 \text{ K})(4)^{0.4/1.4} = 378.9 \text{ K}$$

$$T_{4s} = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (283 \text{ K})(4)^{0.4/1.4} = 420.5 \text{ K}$$

$$T_{6s} = T_5 \left( \frac{P_6}{P_5} \right)^{(k-1)/k} = (283 \text{ K}) \left( \frac{1}{16} \right)^{0.4/1.4} = 128.2 \text{ K}$$

and

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 255 + (378.9 - 255) / 0.85 = 400.8 \text{ K}$$

$$\eta_C = \frac{h_{4s} - h_3}{h_4 - h_3} = \frac{T_{4s} - T_3}{T_4 - T_3} \longrightarrow T_4 = T_3 + (T_{4s} - T_3) / \eta_C = 283 + (420.5 - 283) / 0.85 = 444.8 \text{ K}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} = \frac{T_5 - T_6}{T_5 - T_{6s}} \longrightarrow T_6 = T_5 - \eta_T (T_5 - T_{6s}) = 283 - (0.95)(283 - 128.2) = 135.9 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_6}{(h_2 - h_1) + (h_4 - h_3) - (h_5 - h_6)} \\ &= \frac{T_1 - T_6}{(T_2 - T_1) + (T_4 - T_3) - (T_5 - T_6)} \\ &= \frac{255 - 135.9}{(400.8 - 255) + (444.8 - 283) - (283 - 135.9)} = \mathbf{0.742} \end{aligned}$$

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_6) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_6)} = \frac{(75,000 / 3600) \text{ kJ/s}}{(1.005 \text{ kJ/kg} \cdot \text{K})(255 - 135.9) \text{ K}} = \mathbf{0.174 \text{ kg/s}}$$

## Absorption Refrigeration Systems

**11-74C** Absorption refrigeration is the kind of refrigeration that involves the absorption of the refrigerant during part of the cycle. In absorption refrigeration cycles, the refrigerant is compressed in the liquid phase instead of in the vapor form.

**11-75C** The main advantage of absorption refrigeration is its being economical in the presence of an inexpensive heat source. Its disadvantages include being expensive, complex, and requiring an external heat source.

**11-76C** In absorption refrigeration, water can be used as the refrigerant in air conditioning applications since the temperature of water never needs to fall below the freezing point.

**11-77C** The fluid in the absorber is cooled to maximize the refrigerant content of the liquid; the fluid in the generator is heated to maximize the refrigerant content of the vapor.

**11-78C** The coefficient of performance of absorption refrigeration systems is defined as

$$\text{COP}_R = \frac{\text{desired output}}{\text{required input}} = \frac{Q_L}{Q_{\text{gen}} + W_{\text{pump,in}}} \cong \frac{Q_L}{Q_{\text{gen}}}$$

**11-79C** The rectifier separates the water from  $\text{NH}_3$  and returns it to the generator. The regenerator transfers some heat from the water-rich solution leaving the generator to the  $\text{NH}_3$ -rich solution leaving the pump.

**11-80** The COP of an absorption refrigeration system that operates at specified conditions is given. It is to be determined whether the given COP value is possible.

**Analysis** The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{300 \text{ K}}{403 \text{ K}}\right) \left(\frac{268}{300 - 268}\right) = 2.14$$

which is slightly greater than 2. Thus the claim is **possible**, but not probable.

**11-81** The conditions at which an absorption refrigeration system operates are specified. The maximum COP this absorption refrigeration system can have is to be determined.

**Analysis** The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{393 \text{ K}}\right) \left(\frac{273}{298 - 273}\right) = \mathbf{2.64}$$

**11-82** The conditions at which an absorption refrigeration system operates are specified. The maximum rate at which this system can remove heat from the refrigerated space is to be determined.

**Analysis** The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{403 \text{ K}}\right) \left(\frac{243}{298 - 243}\right) = 1.15$$

Thus,

$$\dot{Q}_{L,\max} = \text{COP}_{R,\max} \dot{Q}_{\text{gen}} = (1.15)(5 \times 10^5 \text{ kJ/h}) = \mathbf{5.75 \times 10^5 \text{ kJ/h}}$$

**11-83E** The conditions at which an absorption refrigeration system operates are specified. The COP is also given. The maximum rate at which this system can remove heat from the refrigerated space is to be determined.

**Analysis** For a COP = 0.55, the rate at which this system can remove heat from the refrigerated space is

$$\dot{Q}_L = \text{COP}_R \dot{Q}_{\text{gen}} = (0.55)(10^5 \text{ Btu/h}) = \mathbf{0.55 \times 10^5 \text{ Btu/h}}$$

**11-84** A reversible absorption refrigerator consists of a reversible heat engine and a reversible refrigerator. The rate at which the steam condenses, the power input to the reversible refrigerator, and the second law efficiency of an actual chiller are to be determined.

**Properties** The enthalpy of vaporization of water at 200°C is  $h_{fg} = 1939.8 \text{ kJ/kg}$  (Table A-4).

**Analysis** (a) The thermal efficiency of the reversible heat engine is

$$\eta_{\text{th,rev}} = 1 - \frac{T_0}{T_s} = 1 - \frac{(25 + 273.15) \text{ K}}{(200 + 273.15) \text{ K}} = 0.370$$

The COP of the reversible refrigerator is

$$\text{COP}_{\text{R,rev}} = \frac{T_L}{T_0 - T_L} = \frac{(-10 + 273.15) \text{ K}}{(25 + 273.15) - (-10 + 273.15) \text{ K}} = 7.52$$

The COP of the reversible absorption refrigerator is

$$\text{COP}_{\text{abs,rev}} = \eta_{\text{th,rev}} \text{COP}_{\text{R,rev}} = (0.370)(7.52) = 2.78$$

The heat input to the reversible heat engine is

$$\dot{Q}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_{\text{abs,rev}}} = \frac{22 \text{ kW}}{2.78} = 7.911 \text{ kW}$$

Then, the rate at which the steam condenses becomes

$$\dot{m}_s = \frac{\dot{Q}_{\text{in}}}{h_{fg}} = \frac{7.911 \text{ kJ/s}}{1939.8 \text{ kJ/kg}} = \mathbf{0.00408 \text{ kg/s}}$$

(b) The power input to the refrigerator is equal to the power output from the heat engine

$$\dot{W}_{\text{in,R}} = \dot{W}_{\text{out,HE}} = \eta_{\text{th,rev}} \dot{Q}_{\text{in}} = (0.370)(7.911 \text{ kW}) = \mathbf{2.93 \text{ kW}}$$

(c) The second-law efficiency of an actual absorption chiller with a COP of 0.7 is

$$\eta_{\text{II}} = \frac{\text{COP}_{\text{actual}}}{\text{COP}_{\text{abs,rev}}} = \frac{0.7}{2.78} = \mathbf{0.252}$$

**Special Topic: Thermoelectric Power Generation and Refrigeration Systems**

**11-85C** The circuit that incorporates both thermal and electrical effects is called a thermoelectric circuit.

**11-86C** When two wires made from different metals joined at both ends (junctions) forming a closed circuit and one of the joints is heated, a current flows continuously in the circuit. This is called the Seebeck effect. When a small current is passed through the junction of two dissimilar wires, the junction is cooled. This is called the Peltier effect.

**11-87C** No.

**11-88C** No.

**11-89C** Yes.

**11-90C** When a thermoelectric circuit is broken, the current will cease to flow, and we can measure the voltage generated in the circuit by a voltmeter. The voltage generated is a function of the temperature difference, and the temperature can be measured by simply measuring voltages.

**11-91C** The performance of thermoelectric refrigerators improves considerably when semiconductors are used instead of metals.

**11-92C** The efficiency of a thermoelectric generator is limited by the Carnot efficiency because a thermoelectric generator fits into the definition of a heat engine with electrons serving as the working fluid.

**11-93E** A thermoelectric generator that operates at specified conditions is considered. The maximum thermal efficiency this thermoelectric generator can have is to be determined.

**Analysis** The maximum thermal efficiency of this thermoelectric generator is the Carnot efficiency,

$$\eta_{\text{th,max}} = \eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{550\text{R}}{800\text{R}} = \mathbf{31.3\%}$$

**11-94** A thermoelectric refrigerator that operates at specified conditions is considered. The maximum COP this thermoelectric refrigerator can have and the minimum required power input are to be determined.

**Analysis** The maximum COP of this thermoelectric refrigerator is the COP of a Carnot refrigerator operating between the same temperature limits,

$$\text{COP}_{\text{max}} = \text{COP}_{\text{R,Carnot}} = \frac{1}{(T_H / T_L) - 1} = \frac{1}{(293\text{ K}) / (268\text{ K}) - 1} = \mathbf{10.72}$$

Thus,

$$\dot{W}_{\text{in,min}} = \frac{\dot{Q}_L}{\text{COP}_{\text{max}}} = \frac{130\text{ W}}{10.72} = \mathbf{12.1\text{ W}}$$

**11-95** A thermoelectric cooler that operates at specified conditions with a given COP is considered. The required power input to the thermoelectric cooler is to be determined.

**Analysis** The required power input is determined from the definition of  $\text{COP}_{\text{R}}$ ,

$$\text{COP}_{\text{R}} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} \longrightarrow \dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_{\text{R}}} = \frac{180\text{ W}}{0.15} = \mathbf{1200\text{ W}}$$

**11-96E** A thermoelectric cooler that operates at specified conditions with a given COP is considered. The required power input to the thermoelectric cooler is to be determined.

**Analysis** The required power input is determined from the definition of  $\text{COP}_{\text{R}}$ ,

$$\text{COP}_{\text{R}} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} \longrightarrow \dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_{\text{R}}} = \frac{20\text{ Btu/min}}{0.15} = 133.3\text{ Btu/min} = \mathbf{3.14\text{ hp}}$$

**11-97** A thermoelectric refrigerator powered by a car battery cools 9 canned drinks in 12 h. The average COP of this refrigerator is to be determined.

**Assumptions** Heat transfer through the walls of the refrigerator is negligible.

**Properties** The properties of canned drinks are the same as those of water at room temperature,  $\rho = 1 \text{ kg/L}$  and  $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-3).

**Analysis** The cooling rate of the refrigerator is simply the rate of decrease of the energy of the canned drinks,

$$m = \rho V = 9 \times (1 \text{ kg/L})(0.350 \text{ L}) = 3.15 \text{ kg}$$

$$Q_{\text{cooling}} = mc\Delta T = (3.15 \text{ kg})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(25 - 3)^\circ\text{C} = 290 \text{ kJ}$$

$$\dot{Q}_{\text{cooling}} = \frac{Q_{\text{cooling}}}{\Delta t} = \frac{290 \text{ kJ}}{12 \times 3600 \text{ s}} = 0.00671 \text{ kW} = 6.71 \text{ W}$$

The electric power consumed by the refrigerator is

$$\dot{W}_{\text{in}} = VI = (12 \text{ V})(3 \text{ A}) = 36 \text{ W}$$

Then the COP of the refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{in}}} = \frac{6.71 \text{ W}}{36 \text{ W}} = \mathbf{0.186} \approx 0.20$$

**11-98E** A thermoelectric cooler is said to cool a 12-oz drink or to heat a cup of coffee in about 15 min. The average rate of heat removal from the drink, the average rate of heat supply to the coffee, and the electric power drawn from the battery of the car are to be determined.

**Assumptions** Heat transfer through the walls of the refrigerator is negligible.

**Properties** The properties of canned drinks are the same as those of water at room temperature,  $c_p = 1.0$  Btu/lbm·°F (Table A-3E).

**Analysis** (a) The average cooling rate of the refrigerator is simply the rate of decrease of the energy content of the canned drinks,

$$Q_{\text{cooling}} = mc_p \Delta T = (0.771 \text{ lbm})(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(78 - 38)^\circ\text{F} = 30.84 \text{ Btu}$$

$$\dot{Q}_{\text{cooling}} = \frac{Q_{\text{cooling}}}{\Delta t} = \frac{30.84 \text{ Btu}}{15 \times 60 \text{ s}} \left( \frac{1055 \text{ J}}{1 \text{ Btu}} \right) = \mathbf{36.2 \text{ W}}$$

(b) The average heating rate of the refrigerator is simply the rate of increase of the energy content of the canned drinks,

$$Q_{\text{heating}} = mc_p \Delta T = (0.771 \text{ lbm})(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(130 - 75)^\circ\text{F} = 42.4 \text{ Btu}$$

$$\dot{Q}_{\text{heating}} = \frac{Q_{\text{heating}}}{\Delta t} = \frac{42.4 \text{ Btu}}{15 \times 60 \text{ s}} \left( \frac{1055 \text{ J}}{1 \text{ Btu}} \right) = \mathbf{49.7 \text{ W}}$$

(c) The electric power drawn from the car battery during cooling and heating is

$$\dot{W}_{\text{in,cooling}} = \frac{\dot{Q}_{\text{cooling}}}{\text{COP}_{\text{cooling}}} = \frac{36.2 \text{ W}}{0.2} = \mathbf{181 \text{ W}}$$

$$\text{COP}_{\text{heating}} = \text{COP}_{\text{cooling}} + 1 = 0.2 + 1 = 1.2$$

$$\dot{W}_{\text{in,heating}} = \frac{\dot{Q}_{\text{heating}}}{\text{COP}_{\text{heating}}} = \frac{49.7 \text{ W}}{1.2} = \mathbf{41.4 \text{ W}}$$

**11-99** The maximum power a thermoelectric generator can produce is to be determined.

**Analysis** The maximum thermal efficiency this thermoelectric generator can have is

$$\eta_{\text{th,max}} = 1 - \frac{T_L}{T_H} = 1 - \frac{303 \text{ K}}{353 \text{ K}} = 0.142$$

Thus,

$$\dot{W}_{\text{out,max}} = \eta_{\text{th,max}} \dot{Q}_{\text{in}} = (0.142)(10^6 \text{ kJ/h}) = 142,000 \text{ kJ/h} = \mathbf{39.4 \text{ kW}}$$

## Review Problems

**11-100** A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP, the condenser and evaporator pressures, and the net work input are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) The COP of this refrigeration cycle is determined from

$$\text{COP}_{R,C} = \frac{1}{(T_H / T_L) - 1} = \frac{1}{(303 \text{ K}) / (253 \text{ K}) - 1} = \mathbf{5.06}$$

(b) The condenser and evaporative pressures are (Table A-11)

$$P_{\text{evap}} = P_{\text{sat}@-20^\circ\text{C}} = \mathbf{132.82 \text{ kPa}}$$

$$P_{\text{cond}} = P_{\text{sat}@30^\circ\text{C}} = \mathbf{770.64 \text{ kPa}}$$

(c) The net work input is determined from

$$h_1 = (h_f + x_1 h_{fg})_{@-20^\circ\text{C}} = 25.49 + (0.15)(212.91) = 57.43 \text{ kJ/kg}$$

$$h_2 = (h_f + x_2 h_{fg})_{@-20^\circ\text{C}} = 25.49 + (0.80)(212.91) = 195.82 \text{ kJ/kg}$$

$$q_L = h_2 - h_1 = 195.82 - 57.43 = 138.4 \text{ kJ/kg}$$

$$w_{\text{net,in}} = \frac{q_L}{\text{COP}_R} = \frac{138.4 \text{ kJ/kg}}{5.06} = \mathbf{27.35 \text{ kJ/kg}}$$

**11-101** A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid is used to heat a house. The rate of heat supply to the house, the volume flow rate of the refrigerant at the compressor inlet, and the COP of this heat pump are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 200 \text{ kPa} = 244.46 \text{ kJ/kg} \\ s_1 = s_g @ 200 \text{ kPa} = 0.93773 \text{ kJ/kg} \cdot \text{K} \\ v_1 = v_g @ 200 \text{ kPa} = 0.099867 \text{ m}^3/\text{kg} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.9 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 275.75 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.9 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 0.9 \text{ MPa} = 101.61 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 101.61 \text{ kJ/kg} \text{ (throttling)}$$

The rate of heat supply to the house is determined from

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.32 \text{ kg/s})(275.75 - 101.61) \text{ kJ/kg} = \mathbf{55.73 \text{ kW}}$$

(b) The volume flow rate of the refrigerant at the compressor inlet is

$$\dot{V}_1 = \dot{m}v_1 = (0.32 \text{ kg/s})(0.099867 \text{ m}^3/\text{kg}) = \mathbf{0.0320 \text{ m}^3/\text{s}}$$

(c) The COP of this heat pump is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{275.75 - 101.61}{275.75 - 244.46} = \mathbf{5.57}$$

**11-102** A relation for the COP of the two-stage refrigeration system with a flash chamber shown in Fig. 11-12 is to be derived.

**Analysis** The coefficient of performance is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}}$$

where

$$q_L = (1 - x_6)(h_1 - h_8) \quad \text{with} \quad x_6 = \frac{h_6 - h_f}{h_{fg}}$$

$$w_{\text{in}} = w_{\text{compI, in}} + w_{\text{compII, in}} = (1 - x_6)(h_2 - h_1) + (1)(h_4 - h_9)$$

**11-103** A two-stage compression refrigeration system using refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the amount of heat removed from the refrigerated space, the compressor work, and the COP are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flashing chamber is adiabatic.

**Analysis** (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables to be (Tables A-11, A-12, and A-13)

$$h_1 = 239.16 \text{ kJ/kg}, \quad h_2 = 260.58 \text{ kJ/kg}$$

$$h_3 = 255.55 \text{ kJ/kg},$$

$$h_5 = 95.47 \text{ kJ/kg}, \quad h_6 = 95.47 \text{ kJ/kg}$$

$$h_7 = 63.94 \text{ kJ/kg}, \quad h_8 = 63.94 \text{ kJ/kg}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{95.47 - 63.94}{191.62} = \mathbf{0.1646}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i$$

$$(1)h_9 = x_6 h_3 + (1 - x_6)h_2$$

$$h_9 = (0.1646)(255.55) + (1 - 0.1646)(260.58) = 259.75 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 0.4 \text{ MPa} \\ h_9 = 259.75 \text{ kJ/kg} \end{array} \right\} s_9 = 0.94168 \text{ kJ/kg} \cdot \text{K}$$

Also,

$$\left. \begin{array}{l} P_4 = 0.8 \text{ MPa} \\ s_4 = s_9 = 0.94168 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_4 = 274.47 \text{ kJ/kg}$$

Then the amount of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$q_L = (1 - x_6)(h_1 - h_8) = (1 - 0.1646)(239.16 - 63.94) \text{ kJ/kg} = \mathbf{146.4 \text{ kJ/kg}}$$

$$\begin{aligned} w_{\text{in}} &= w_{\text{compI, in}} + w_{\text{compII, in}} = (1 - x_6)(h_2 - h_1) + (1)(h_4 - h_9) \\ &= (1 - 0.1646)(260.58 - 239.16) \text{ kJ/kg} + (274.47 - 259.75) \text{ kJ/kg} = \mathbf{32.6 \text{ kJ/kg}} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{146.4 \text{ kJ/kg}}{32.6 \text{ kJ/kg}} = \mathbf{4.49}$$

**11-104** A refrigerator operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy loss is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In this cycle, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. The compression process is not isentropic. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\begin{aligned} T_1 = -10^\circ\text{C} \quad \left. \begin{array}{l} h_1 = h_g @ -10^\circ\text{C} = 244.51 \text{ kJ/kg} \\ \text{sat. vapor} \end{array} \right\} \quad s_1 = s_g @ -10^\circ\text{C} = 0.93766 \text{ kJ/kg} \cdot \text{K} \\ P_2 = 700 \text{ kPa} \quad \left. \begin{array}{l} h_{2s} = 270.38 \text{ kJ/kg} \\ s_2 = s_1 \end{array} \right\} \\ P_3 = 700 \text{ kPa} \quad \left. \begin{array}{l} h_3 = h_f @ 700 \text{ kPa} = 88.82 \text{ kJ/kg} \\ \text{sat. liquid} \end{array} \right\} \quad s_3 = s_f @ 700 \text{ kPa} = 0.33230 \text{ kJ/kg} \cdot \text{K} \\ h_4 \cong h_3 = 88.82 \text{ kJ/kg} \quad (\text{throttling}) \\ T_4 = -10^\circ\text{C} \quad \left. \begin{array}{l} s_4 = 0.34605 \text{ kJ/kg} \cdot \text{K} \\ h_4 = 88.82 \text{ kJ/kg} \end{array} \right\} \end{aligned}$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 244.51 + \frac{270.38 - 244.51}{0.85} = 274.95 \text{ kJ/kg}$$

and 
$$\left. \begin{array}{l} P_2 = 700 \text{ kPa} \\ h_2 = 274.95 \text{ kJ/kg} \end{array} \right\} s_2 = 0.95252 \text{ kJ/kg}$$

The heat added in the evaporator and that rejected in the condenser are

$$\begin{aligned} q_L &= h_1 - h_4 = (244.51 - 88.82) \text{ kJ/kg} = 155.69 \text{ kJ/kg} \\ q_H &= h_2 - h_3 = (274.95 - 88.82) \text{ kJ/kg} = 186.13 \text{ kJ/kg} \end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} x_{\text{destroyed}, 12} &= T_0 (s_2 - s_1) = (295 \text{ K})(0.95252 - 0.93766) \text{ kJ/kg} \cdot \text{K} = 4.38 \text{ kJ/kg} \\ x_{\text{destroyed}, 23} &= T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) = (295 \text{ K}) \left( 0.33230 - 0.95252 + \frac{186.13 \text{ kJ/kg}}{295 \text{ K}} \right) = 3.17 \text{ kJ/kg} \\ x_{\text{destroyed}, 34} &= T_0 (s_4 - s_3) = (295 \text{ K})(0.34605 - 0.33230) \text{ kJ/kg} \cdot \text{K} = 4.06 \text{ kJ/kg} \\ x_{\text{destroyed}, 41} &= T_0 \left( s_1 - s_4 - \frac{q_L}{T_L} \right) = (295 \text{ K}) \left( 0.93766 - 0.34605 - \frac{155.69 \text{ kJ/kg}}{273 \text{ K}} \right) = \mathbf{6.29 \text{ kJ/kg}} \end{aligned}$$

The greatest exergy destruction occurs in the evaporator. Note that heat is absorbed from freezing water at  $0^\circ\text{C}$  (273 K) and rejected to the ambient air at  $22^\circ\text{C}$  (295 K), which is also taken as the dead state temperature. Alternatively, one may use the standard  $25^\circ\text{C}$  (298 K) as the dead state temperature, and perform the calculations accordingly.

**11-105** A refrigerator operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy loss is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = -10^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -10^\circ\text{C} = 244.51 \text{ kJ/kg} \\ s_1 = s_g @ -10^\circ\text{C} = 0.93766 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 700 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 270.38 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 700 \text{ kPa} \\ T_3 = T_{\text{sat}} @ 700 \text{ kPa} - 2.7 \\ \quad = 26.7 - 2.7 = 24^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 \cong h_f @ 24^\circ\text{C} = 84.98 \text{ kJ/kg} \\ s_3 \cong s_f @ 24^\circ\text{C} = 0.31958 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$h_4 \cong h_3 = 84.98 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_4 = -10^\circ\text{C} \\ h_4 = 84.98 \text{ kJ/kg} \end{array} \right\} s_4 = 0.33146 \text{ kJ/kg} \cdot \text{K}$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 244.51 + \frac{270.38 - 244.51}{0.85} = 274.95 \text{ kJ/kg}$$

$$\text{and } \left. \begin{array}{l} P_2 = 700 \text{ kPa} \\ h_2 = 274.95 \text{ kJ/kg} \end{array} \right\} s_2 = 0.95252 \text{ kJ/kg}$$

The heat added in the evaporator and that rejected in the condenser are

$$q_L = h_1 - h_4 = (244.51 - 84.98) \text{ kJ/kg} = 159.53 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = (274.95 - 84.98) \text{ kJ/kg} = 189.97 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed}, 12} = T_0 (s_2 - s_1) = (295 \text{ K})(0.95252 - 0.93766) \text{ kJ/kg} \cdot \text{K} = 4.38 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 23} = T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) = (295 \text{ K}) \left( 0.31958 - 0.95252 + \frac{189.97 \text{ kJ/kg}}{295 \text{ K}} \right) = 3.25 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 34} = T_0 (s_4 - s_3) = (295 \text{ K})(0.33146 - 0.31958) \text{ kJ/kg} \cdot \text{K} = 3.50 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 41} = T_0 \left( s_1 - s_4 - \frac{q_L}{T_L} \right) = (295 \text{ K}) \left( 0.93766 - 0.33146 - \frac{159.53 \text{ kJ/kg}}{273 \text{ K}} \right) = \mathbf{6.44 \text{ kJ/kg}}$$

The greatest exergy destruction occurs in the evaporator. Note that heat is absorbed from freezing water at  $0^\circ\text{C}$  (273 K) and rejected to the ambient air at  $22^\circ\text{C}$  (295 K), which is also taken as the dead state temperature. Alternatively, one may use the standard  $25^\circ\text{C}$  (298 K) as the dead state temperature, and perform the calculations accordingly.

**11-106** A refrigerator operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy loss is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** In this cycle, the refrigerant leaves the condenser as saturated liquid at the condenser pressure. The compression process is not isentropic. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = P_{\text{sat @ } -37^\circ\text{C}} = 60 \text{ kPa} \\ T_1 = -37 + 7 = -30^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 233.09 \text{ kJ/kg} \\ s_1 = 0.9865 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1.2 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_{2s} = 298.11 \text{ kJ/kg} \\ s_{2s} = s_1 \end{array}$$

$$\left. \begin{array}{l} P_3 = 1.2 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 1.2 \text{ MPa} = 117.77 \text{ kJ/kg} \\ s_3 = s_f @ 1.2 \text{ MPa} = 0.42441 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$h_4 \cong h_3 = 117.77 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_4 = -37^\circ\text{C} \\ h_4 = 117.77 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} x_4 = 0.5089 \\ s_4 = 0.4988 \text{ kJ/kg} \cdot \text{K} \end{array}$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 233.09 + \frac{298.11 - 233.09}{0.90} = 305.33 \text{ kJ/kg}$$

and  $\left. \begin{array}{l} P_2 = 1.2 \text{ MPa} \\ h_2 = 305.33 \text{ Btu/lbm} \end{array} \right\} s_2 = 1.0075 \text{ kJ/kg} \cdot \text{K}$

The heat added in the evaporator and that rejected in the condenser are

$$q_L = h_1 - h_4 = (233.09 - 117.77) \text{ kJ/kg} = 115.32 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = (305.33 - 117.77) \text{ kJ/kg} = 187.56 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed}, 12} = T_0 (s_2 - s_1) = (303 \text{ K})(1.0075 - 0.9865) \text{ kJ/kg} \cdot \text{K} = 6.36 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 23} = T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) = (303 \text{ K}) \left( 0.42441 - 1.0075 + \frac{187.56 \text{ kJ/kg}}{303 \text{ K}} \right) = 10.88 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 34} = T_0 (s_4 - s_3) = (303 \text{ K})(0.4988 - 0.42441) \text{ kJ/kg} \cdot \text{K} = \mathbf{22.54 \text{ kJ/kg}}$$

$$x_{\text{destroyed}, 41} = T_0 \left( s_1 - s_4 - \frac{q_L}{T_L} \right) = (303 \text{ K}) \left( 0.9865 - 0.4988 - \frac{115.32 \text{ kJ/kg}}{(-34 + 273) \text{ K}} \right) = 1.57 \text{ kJ/kg}$$

The greatest exergy destruction occurs in the expansion valve. Note that heat is absorbed from fruits at  $-34^\circ\text{C}$  (239 K) and rejected to the ambient air at  $30^\circ\text{C}$  (303 K), which is also taken as the dead state temperature. Alternatively, one may use the standard  $25^\circ\text{C}$  (298 K) as the dead state temperature, and perform the calculations accordingly.

**11-107** A refrigerator operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy loss is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = P_{\text{sat @ } -37^\circ\text{C}} = 60 \text{ kPa} \\ T_1 = -37 + 7 = -30^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 233.09 \text{ kJ/kg} \\ s_1 = 0.9865 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1.2 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 298.11 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1.2 \text{ MPa} \\ T_3 = T_{\text{sat @ } 1.2 \text{ MPa}} - 6.3 \\ \quad = 46.3 - 6.3 = 40^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 \cong h_f @ 40^\circ\text{C} = 108.26 \text{ kJ/kg} \\ s_3 \cong s_f @ 40^\circ\text{C} = 0.39486 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$h_4 \cong h_3 = 108.26 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_4 = -37^\circ\text{C} \\ h_4 = 108.26 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} x_4 = 0.4665 \\ s_4 = 0.4585 \text{ kJ/kg} \cdot \text{K} \end{array}$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 233.09 + \frac{298.11 - 233.09}{0.90} = 305.33 \text{ kJ/kg}$$

$$\text{and} \quad \left. \begin{array}{l} P_2 = 1.2 \text{ MPa} \\ h_2 = 305.33 \text{ Btu/lbm} \end{array} \right\} s_2 = 1.0075 \text{ kJ/kg} \cdot \text{K}$$

The heat added in the evaporator and that rejected in the condenser are

$$q_L = h_1 - h_4 = (233.09 - 108.26) \text{ kJ/kg} = 124.83 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = (305.33 - 108.26) \text{ kJ/kg} = 197.07 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed}, 12} = T_0 (s_2 - s_1) = (303 \text{ K})(1.0075 - 0.9865) \text{ kJ/kg} \cdot \text{K} = 6.36 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 23} = T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) = (303 \text{ K}) \left( 0.39486 - 1.0075 + \frac{197.07 \text{ kJ/kg}}{303 \text{ K}} \right) = 11.44 \text{ kJ/kg}$$

$$x_{\text{destroyed}, 34} = T_0 (s_4 - s_3) = (303 \text{ K})(0.4585 - 0.39486) \text{ kJ/kg} \cdot \text{K} = \mathbf{19.28 \text{ kJ/kg}}$$

$$x_{\text{destroyed}, 41} = T_0 \left( s_1 - s_4 - \frac{q_L}{T_L} \right) = (303 \text{ K}) \left( 0.9865 - 0.4585 - \frac{124.83 \text{ kJ/kg}}{(-34 + 273) \text{ K}} \right) = 1.73 \text{ kJ/kg}$$

The greatest exergy destruction occurs in the expansion valve. Note that heat is absorbed from fruits at  $-34^\circ\text{C}$  (239 K) and rejected to the ambient air at  $30^\circ\text{C}$  (303 K), which is also taken as the dead state temperature. Alternatively, one may use the standard  $25^\circ\text{C}$  (298 K) as the dead state temperature, and perform the calculations accordingly.

**11-108E** A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The cooling load of both evaporators per unit of flow through the compressor and the COP of the system are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 160 \text{ psia} = 48.519 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 48.519 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 30^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 30^\circ\text{F} = 107.40 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} T_7 = -29.5^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ -29.5^\circ\text{F} = 98.68 \text{ Btu/lbm}$$

For a unit mass flowing through the compressor, the fraction of mass flowing through Evaporator II is denoted by  $x$  and that through Evaporator I is  $y$  ( $y = 1-x$ ). From the cooling loads specification,

$$\begin{aligned} \dot{Q}_{L, \text{evap 1}} &= 2\dot{Q}_{L, \text{evap 2}} \\ x(h_5 - h_4) &= 2y(h_7 - h_6) \end{aligned}$$

where

$$x = 1 - y$$

Combining these results and solving for  $y$  gives

$$y = \frac{h_5 - h_4}{2(h_7 - h_6) + (h_5 - h_4)} = \frac{107.40 - 48.519}{2(98.68 - 48.519) + (107.40 - 48.519)} = 0.3698$$

Then,

$$x = 1 - y = 1 - 0.3698 = 0.6302$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$xh_5 + yh_7 = h_1 \longrightarrow h_1 = \frac{xh_5 + yh_7}{1} = \frac{(0.6302)(107.40) + (0.3698)(98.68)}{1} = 104.18 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = P_{\text{sat @ } -29.5^\circ\text{F}} \cong 10 \text{ psia} \\ h_1 = 104.18 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2418 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 131.14 \text{ Btu/lbm}$$

The cooling load of both evaporators per unit mass through the compressor is

$$\begin{aligned} q_L &= x(h_5 - h_4) + y(h_7 - h_6) \\ &= (0.6302)(107.40 - 48.519) \text{ Btu/lbm} + (0.3698)(98.68 - 48.519) \text{ Btu/lbm} \\ &= \mathbf{55.66 \text{ Btu/lbm}} \end{aligned}$$

The work input to the compressor is

$$w_{\text{in}} = h_2 - h_1 = (131.14 - 104.18) \text{ Btu/lbm} = 26.96 \text{ Btu/lbm}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{55.66 \text{ Btu/lbm}}{26.96 \text{ Btu/lbm}} = \mathbf{2.06}$$

**11-109E** A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Prob. 11-107E and the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\begin{aligned}s_1 &= s_2 = 0.2418 \text{ Btu/lbm} \cdot \text{R} \\s_3 &= 0.09774 \text{ Btu/lbm} \cdot \text{R} \\s_4 &= 0.10238 \text{ Btu/lbm} \cdot \text{R} \\s_5 &= 0.22260 \text{ Btu/lbm} \cdot \text{R} \\s_6 &= 0.11286 \text{ Btu/lbm} \cdot \text{R} \\s_7 &= 0.22948 \text{ Btu/lbm} \cdot \text{R} \\x &= 0.6302 \\y &= 1 - x = 0.3698 \\q_{L,45} &= h_5 - h_4 = 58.881 \text{ Btu/lbm} \\q_{L,67} &= h_7 - h_6 = 50.161 \text{ Btu/lbm} \\q_H &= 82.621 \text{ Btu/lbm}\end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives the exergy destructions per unit mass flowing through the compressor:

$$\begin{aligned}x_{\text{destroyed},23} &= T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) = (555 \text{ R}) \left( 0.09774 - 0.2418 + \frac{82.621 \text{ Btu/lbm}}{555 \text{ R}} \right) = 2.67 \text{ Btu/lbm} \\x_{\text{destroyed},346} &= T_0 (x s_4 + y s_6 - s_3) \\&= (555 \text{ R}) (0.6302 \times 0.10238 + 0.3698 \times 0.11286 - 0.09774) \text{ Btu/lbm} \cdot \text{R} = 4.73 \text{ Btu/lbm} \\x_{\text{destroyed},45} &= x T_0 \left( s_5 - s_4 - \frac{q_{L,45}}{T_L} \right) \\&= (0.6302)(555 \text{ R}) \left( 0.22260 - 0.10238 - \frac{58.881 \text{ Btu/lbm}}{495 \text{ R}} \right) = 0.44 \text{ Btu/lbm} \\x_{\text{destroyed},67} &= y T_0 \left( s_7 - s_6 - \frac{q_{L,67}}{T_L} \right) \\&= (0.3698)(555 \text{ R}) \left( 0.22948 - 0.11286 - \frac{50.161 \text{ Btu/lbm}}{440 \text{ R}} \right) = 0.54 \text{ Btu/lbm} \\\dot{X}_{\text{destroyed},\text{mixing}} &= T_0 (s_1 - x s_5 - y s_6) \\&= (555 \text{ R}) [0.2418 - (0.6302)(0.22260) - (0.3698)(0.11286)] = \mathbf{3.18 \text{ Btu/lbm}}\end{aligned}$$

For isentropic processes, the exergy destruction is zero:

$$\dot{X}_{\text{destroyed},12} = 0$$

The greatest exergy destruction occurs during the mixing process. Note that heat is absorbed in evaporator 2 from a reservoir at  $-20^\circ\text{F}$  (440 R), in evaporator 1 from a reservoir at  $35^\circ\text{F}$  (495 R), and rejected to a reservoir at  $95^\circ\text{F}$  (555 R), which is also taken as the dead state temperature.

**11-110** A two-stage compression refrigeration system with a separation unit is considered. The rate of cooling and the power requirement are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 8.9^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 8.9^\circ\text{C} = 255.55 \text{ kJ/kg} \\ s_1 = s_g @ 8.9^\circ\text{C} = 0.92691 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1400 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 281.49 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1400 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1400 \text{ kPa} = 127.22 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 127.22 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 8.9^\circ\text{C} \\ \text{sat. liquid} \end{array} \right\} h_5 = h_f @ 8.9^\circ\text{C} = 63.94 \text{ kJ/kg}$$

$$h_6 \cong h_5 = 63.94 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_7 = -32^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_7 = h_g @ -32^\circ\text{C} = 230.91 \text{ kJ/kg} \\ s_7 = s_g @ -32^\circ\text{C} = 0.95813 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_8 = P_{\text{sat}} @ 8.9^\circ\text{C} = 400 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_8 = 264.51 \text{ kJ/kg}$$

An energy balance on the separator gives

$$\dot{m}_6(h_8 - h_5) = \dot{m}_2(h_1 - h_4) \longrightarrow \dot{m}_6 = \dot{m}_2 \frac{h_1 - h_4}{h_8 - h_5} = (2 \text{ kg/s}) \frac{255.55 - 127.22}{264.51 - 63.94} = 1.280 \text{ kg/s}$$

The rate of cooling produced by this system is then

$$\dot{Q}_L = \dot{m}_6(h_7 - h_6) = (1.280 \text{ kg/s})(230.91 - 63.94) \text{ kJ/kg} = \mathbf{213.7 \text{ kJ/s}}$$

The total power input to the compressors is

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_6(h_8 - h_7) + \dot{m}_2(h_2 - h_1) \\ &= (1.280 \text{ kg/s})(264.51 - 230.91) \text{ kJ/kg} + (2 \text{ kg/s})(281.49 - 255.55) \text{ kJ/kg} = \mathbf{94.89 \text{ kW}} \end{aligned}$$

**11-111** A two-stage vapor-compression refrigeration system with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From Prob. 11-109 and the refrigerant tables (Tables A-11, A-12, and A-13),

$$s_1 = s_2 = 0.92691 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = 0.45315 \text{ kJ/kg} \cdot \text{K}$$

$$s_4 = 0.4720 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = 0.24761 \text{ kJ/kg} \cdot \text{K}$$

$$s_6 = 0.2658 \text{ kJ/kg} \cdot \text{K}$$

$$s_7 = s_8 = 0.95813 \text{ kJ/kg} \cdot \text{K}$$

$$\dot{m}_{\text{upper}} = 2 \text{ kg/s}$$

$$\dot{m}_{\text{lower}} = 1.280 \text{ kg/s}$$

$$q_L = h_7 - h_6 = 166.97 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = 154.27 \text{ kJ/kg}$$

$$T_L = -18 + 273 = 255 \text{ K}$$

$$T_H = T_0 = 25 + 273 = 298 \text{ K}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left( s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} \dot{X}_{\text{destroyed}, 23} &= \dot{m}_{\text{upper}} T_0 \left( s_3 - s_2 + \frac{q_H}{T_H} \right) \\ &= (2 \text{ kg/s})(298 \text{ K}) \left( 0.45315 - 0.92691 + \frac{154.27 \text{ kJ/kg}}{298 \text{ K}} \right) = \mathbf{26.18 \text{ kW}} \end{aligned}$$

$$\dot{X}_{\text{destroyed}, 34} = \dot{m}_{\text{upper}} T_0 (s_4 - s_3) = (2 \text{ kg/s})(298 \text{ K})(0.4720 - 0.45315) \text{ kJ/kg} \cdot \text{K} = 11.23 \text{ kW}$$

$$\dot{X}_{\text{destroyed}, 56} = \dot{m}_{\text{lower}} T_0 (s_6 - s_5) = (1.280 \text{ kg/s})(298 \text{ K})(0.2658 - 0.24761) \text{ kJ/kg} \cdot \text{K} = 6.94 \text{ kW}$$

$$\begin{aligned} \dot{X}_{\text{destroyed}, 67} &= \dot{m}_{\text{lower}} T_0 \left( s_7 - s_6 - \frac{q_L}{T_L} \right) \\ &= (1.280 \text{ kg/s})(298 \text{ K}) \left( 0.95813 - 0.2658 - \frac{166.97 \text{ kJ/kg}}{255 \text{ K}} \right) = 14.32 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{X}_{\text{destroyed}, \text{separator}} &= T_0 [\dot{m}_{\text{lower}} (s_5 - s_8) - \dot{m}_{\text{upper}} (s_1 - s_4)] \\ &= (298 \text{ K}) [(1.280 \text{ kg/s})(0.24761 - 0.95813) + (2 \text{ kg/s})(0.92691 - 0.4720)] = 0.11 \text{ kW} \end{aligned}$$

For isentropic processes, the exergy destruction is zero:

$$\dot{X}_{\text{destroyed}, 12} = 0$$

$$\dot{X}_{\text{destroyed}, 78} = 0$$

Note that heat is absorbed from a reservoir at 0°F (460 R) and rejected to the standard ambient air at 77°F (537 R), which is also taken as the dead state temperature. The greatest exergy destruction occurs during the condensation process.

**11-112** A regenerative gas refrigeration cycle with helium as the working fluid is considered. The temperature of the helium at the turbine inlet, the COP of the cycle, and the net power input required are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Helium is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of helium are  $c_p = 5.1926$  kJ/kg·K and  $k = 1.667$  (Table A-2).

**Analysis** (a) The temperature of the helium at the turbine inlet is determined from an energy balance on the regenerator,

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \quad \phi^0(\text{steady}) = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \longrightarrow \dot{m}(h_3 - h_4) = \dot{m}(h_1 - h_6)\end{aligned}$$

or,

$$\dot{m} c_p (T_3 - T_4) = \dot{m} c_p (T_1 - T_6) \longrightarrow T_3 - T_4 = T_1 - T_6$$

Thus,

$$T_4 = T_3 - T_1 + T_6 = 20^\circ\text{C} - (-10^\circ\text{C}) + (-25^\circ\text{C}) = 5^\circ\text{C} = 278 \text{ K}$$

(b) From the isentropic relations,

$$\begin{aligned}T_2 &= T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (263 \text{ K})(3)^{0.667/1.667} = 408.2 \text{ K} = 135.2^\circ\text{C} \\ T_5 &= T_4 \left( \frac{P_5}{P_4} \right)^{(k-1)/k} = (278 \text{ K}) \left( \frac{1}{3} \right)^{0.667/1.667} = 179.1 \text{ K} = -93.9^\circ\text{C}\end{aligned}$$

Then the COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned}\text{COP}_R &= \frac{q_L}{w_{\text{net},\text{in}}} = \frac{q_L}{w_{\text{comp},\text{in}} - w_{\text{turb},\text{out}}} = \frac{h_6 - h_5}{(h_2 - h_1) - (h_4 - h_5)} \\ &= \frac{T_6 - T_5}{(T_2 - T_1) - (T_4 - T_5)} = \frac{-25^\circ\text{C} - (-93.9^\circ\text{C})}{[135.2 - (-10)]^\circ\text{C} - [5 - (-93.9)]^\circ\text{C}} = \mathbf{1.49}\end{aligned}$$

(c) The net power input is determined from

$$\begin{aligned}\dot{W}_{\text{net},\text{in}} &= \dot{W}_{\text{comp},\text{in}} - \dot{W}_{\text{turb},\text{out}} = \dot{m}[(h_2 - h_1) - (h_4 - h_5)] \\ &= \dot{m} c_p [(T_2 - T_1) - (T_4 - T_5)] \\ &= (0.45 \text{ kg/s})(5.1926 \text{ kJ/kg} \cdot ^\circ\text{C})[135.2 - (-10)] - [5 - (-93.9)] \\ &= \mathbf{108.2 \text{ kW}}\end{aligned}$$

**11-113** An absorption refrigeration system operating at specified conditions is considered. The minimum rate of heat supply required is to be determined.

**Analysis** The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298\text{K}}{358\text{K}}\right) \left(\frac{263}{298 - 263}\right) = 1.259$$

Thus,

$$\dot{Q}_{\text{gen,min}} = \frac{\dot{Q}_L}{\text{COP}_{R,\max}} = \frac{12 \text{ kW}}{1.259} = \mathbf{9.53 \text{ kW}}$$

**11-114 EES** Problem 11-113 is reconsidered. The effect of the source temperature on the minimum rate of heat supply is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

"Input Data:"

T\_L = -10 [C]

T\_0 = 25 [C]

T\_s = 85 [C]

Q\_dot\_L = 8 [kW]

"The maximum COP that this refrigeration system can have is:"

$\text{COP}_{R,\max} = (1 - (T_0 + 273)/(T_s + 273)) * ((T_L + 273)/(T_0 - T_L))$

"The minimum rate of heat supply is:"

$Q_{\text{dot\_gen\_min}} = Q_{\text{dot\_L}} / \text{COP}_{R,\max}$

| $Q_{\text{genmin}}$ [kW] | $T_s$ [C] |
|--------------------------|-----------|
| 13.76                    | 50        |
| 8.996                    | 65        |
| 6.833                    | 80        |
| 5.295                    | 100       |
| 4.237                    | 125       |
| 3.603                    | 150       |
| 2.878                    | 200       |
| 2.475                    | 250       |

**11-115** A room is cooled adequately by a 5000 Btu/h window air-conditioning unit. The rate of heat gain of the room when the air-conditioner is running continuously is to be determined.

**Assumptions** **1** The heat gain includes heat transfer through the walls and the roof, infiltration heat gain, solar heat gain, internal heat gain, etc. **2** Steady operating conditions exist.

**Analysis** The rate of heat gain of the room in steady operation is simply equal to the cooling rate of the air-conditioning system,

$$\dot{Q}_{\text{heat gain}} = \dot{Q}_{\text{cooling}} = \mathbf{5,000 \text{ Btu/h}}$$

**11-116** A regenerative gas refrigeration cycle using air as the working fluid is considered. The effectiveness of the regenerator, the rate of heat removal from the refrigerated space, the COP of the cycle, and the refrigeration load and the COP if this system operated on the simple gas refrigeration cycle are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

**Analysis** (a) For this problem, we use the properties of air from EES:

$$\begin{aligned} T_1 = 0^\circ\text{C} &\longrightarrow h_1 = 273.40 \text{ kJ/kg} \\ P_1 = 100 \text{ kPa} \\ T_1 = 0^\circ\text{C} &\left. \vphantom{\begin{aligned} T_1 = 0^\circ\text{C} \\ P_1 = 100 \text{ kPa} \end{aligned}} \right\} s_1 = 5.6110 \text{ kJ/kg}\cdot\text{K} \\ P_2 = 500 \text{ kPa} \\ s_2 = s_1 &\left. \vphantom{\begin{aligned} P_2 = 500 \text{ kPa} \\ s_2 = s_1 \end{aligned}} \right\} h_{2s} = 433.50 \text{ kJ/kg} \end{aligned}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{433.50 - 273.40}{h_2 - 273.40}$$

$$h_2 = 473.52 \text{ kJ/kg}$$

$$T_3 = 35^\circ\text{C} \longrightarrow h_3 = 308.63 \text{ kJ/kg}$$

For the turbine inlet and exit we have

$$T_5 = -80^\circ\text{C} \longrightarrow h_5 = 193.45 \text{ kJ/kg}$$

$$T_4 = ? \longrightarrow h_4 =$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}}$$

$$\begin{aligned} P_1 = 100 \text{ kPa} \\ T_1 = 0^\circ\text{C} &\left. \vphantom{\begin{aligned} P_1 = 100 \text{ kPa} \\ T_1 = 0^\circ\text{C} \end{aligned}} \right\} s_1 = 5.6110 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_4 = 500 \text{ kPa} \\ T_4 = ? &\left. \vphantom{\begin{aligned} P_4 = 500 \text{ kPa} \\ T_4 = ? \end{aligned}} \right\} s_4 = \end{aligned}$$

$$\begin{aligned} P_5 = 500 \text{ kPa} \\ s_5 = s_4 &\left. \vphantom{\begin{aligned} P_5 = 500 \text{ kPa} \\ s_5 = s_4 \end{aligned}} \right\} h_{5s} = \end{aligned}$$

We can determine the temperature at the turbine inlet from EES using the above relations. A hand solution would require a trial-error approach.

$$T_4 = 281.8 \text{ K}, \quad h_4 = 282.08 \text{ kJ/kg}$$

An energy balance on the regenerator gives

$$h_6 = h_1 - h_3 + h_4 = 273.40 - 308.63 + 282.08 = 246.85 \text{ kJ/kg}$$

The effectiveness of the regenerator is determined from

$$\varepsilon_{\text{regen}} = \frac{h_3 - h_4}{h_3 - h_6} = \frac{308.63 - 282.08}{308.63 - 246.85} = \mathbf{0.430}$$

(b) The refrigeration load is

$$\dot{Q}_L = \dot{m}(h_6 - h_5) = (0.4 \text{ kg/s})(246.85 - 193.45) \text{ kJ/kg} = \mathbf{21.36 \text{ kW}}$$

(c) The turbine and compressor powers and the COP of the cycle are

$$\dot{W}_{C,\text{in}} = \dot{m}(h_2 - h_1) = (0.4 \text{ kg/s})(473.52 - 273.40) \text{ kJ/kg} = 80.05 \text{ kW}$$

$$\dot{W}_{T,\text{out}} = \dot{m}(h_4 - h_5) = (0.4 \text{ kg/s})(282.08 - 193.45) \text{ kJ/kg} = 35.45 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{\dot{Q}_L}{\dot{W}_{C,\text{in}} - \dot{W}_{T,\text{out}}} = \frac{21.36}{80.05 - 35.45} = \mathbf{0.479}$$

(d) The simple gas refrigeration cycle analysis is as follows:

$$h_1 = 273.40 \text{ kJ/kg}$$

$$h_2 = 473.52 \text{ kJ/kg}$$

$$h_3 = 308.63 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ T_3 = 35^\circ\text{C} \end{array} \right\} s_3 = 5.2704 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_1 = 100 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 194.52 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.85 = \frac{308.63 - h_4}{308.63 - 194.52} \longrightarrow h_4 = 211.64 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.4 \text{ kg/s})(273.40 - 211.64) \text{ kJ/kg} = \mathbf{24.70 \text{ kW}}$$

$$\dot{W}_{\text{net,in}} = \dot{m}(h_2 - h_1) - \dot{m}(h_3 - h_4) = (0.4 \text{ kg/s})[(473.52 - 273.40) - (308.63 - 211.64) \text{ kJ/kg}] = 41.25 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{24.70}{41.25} = \mathbf{0.599}$$

**11-117** A heat pump water heater has a COP of 2.2 and consumes 2 kW when running. It is to be determined if this heat pump can be used to meet the cooling needs of a room by absorbing heat from it.

**Assumptions** The COP of the heat pump remains constant whether heat is absorbed from the outdoor air or room air.

**Analysis** The COP of the heat pump is given to be 2.2. Then the COP of the air-conditioning system becomes

$$\text{COP}_{\text{air-cond}} = \text{COP}_{\text{heat pump}} - 1 = 2.2 - 1 = 1.2$$

Then the rate of cooling (heat absorption from the air) becomes

$$\dot{Q}_{\text{cooling}} = \text{COP}_{\text{air-cond}} \dot{W}_{\text{in}} = (1.2)(2 \text{ kW}) = 2.4 \text{ kW} = 8640 \text{ kJ/h}$$

since 1 kW = 3600 kJ/h. We conclude that this heat pump **can meet** the cooling needs of the room since its cooling rate is greater than the rate of heat gain of the room.

**11-118** An innovative vapor-compression refrigeration system with a heat exchanger is considered. The system's COP is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = T_{\text{sat}} @ 800 \text{ kPa} - 11.3 \\ = 31.3 - 11.3 = 20^\circ\text{C} \\ P_4 = 800 \text{ kPa} \end{array} \right\} h_4 \cong h_f @ 20^\circ\text{C} = 79.32 \text{ kJ/kg}$$

$$h_5 \cong h_4 = 79.32 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_6 = -10.1^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_6 = h_g @ -10.1^\circ\text{C} = 244.46 \text{ kJ/kg} \\ P_6 = P_{\text{sat}} @ -10.1^\circ\text{C} = 200 \text{ kPa} \end{array}$$

An energy balance on the heat exchanger gives

$$\dot{m}(h_1 - h_6) = \dot{m}(h_3 - h_4) \longrightarrow h_1 = h_3 - h_4 + h_6 = 95.47 - 79.32 + 244.46 = 260.61 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ h_1 = 260.61 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9970 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 292.17 \text{ kJ/kg}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{in}} = \frac{h_6 - h_5}{h_2 - h_1} = \frac{244.46 - 79.32}{292.17 - 260.61} = \mathbf{5.23}$$

**11-119** An innovative vapor-compression refrigeration system with a heat exchanger is considered. The system's COP is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = T_{\text{sat}} @ 800 \text{ kPa} - 21.3 \\ = 31.3 - 21.3 = 10^\circ\text{C} \\ P_4 = 800 \text{ kPa} \end{array} \right\} h_4 \cong h_f @ 10^\circ\text{C} = 65.43 \text{ kJ/kg}$$

$$h_5 \cong h_4 = 65.43 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_6 = -10.1^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_6 = h_g @ -10.1^\circ\text{C} = 244.46 \text{ kJ/kg} \\ P_6 = P_{\text{sat}} @ -10.1^\circ\text{C} = 200 \text{ kPa} \end{array}$$

An energy balance on the heat exchanger gives

$$\dot{m}(h_1 - h_6) = \dot{m}(h_3 - h_4) \longrightarrow h_1 = h_3 - h_4 + h_6 = 95.47 - 65.43 + 244.46 = 274.50 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ h_1 = 274.50 \text{ kJ/kg} \end{array} \right\} s_1 = 1.0449 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 308.28 \text{ kJ/kg}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{in}} = \frac{h_6 - h_5}{h_2 - h_1} = \frac{244.46 - 65.43}{308.28 - 274.50} = \mathbf{5.30}$$

**11-120** An ideal gas refrigeration cycle with three stages of compression with intercooling using air as the working fluid is considered. The COP of this system is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** From the isentropic relations,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (253 \text{ K})(5)^{0.4/1.4} = 400.7 \text{ K}$$

$$T_4 = T_6 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (288 \text{ K})(5)^{0.4/1.4} = 456.1 \text{ K}$$

$$T_8 = T_7 \left( \frac{P_8}{P_7} \right)^{(k-1)/k} = (288 \text{ K}) \left( \frac{1}{5 \times 5 \times 5} \right)^{0.4/1.4} = 72.5 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_8}{(h_2 - h_1) + (h_4 - h_3) + (h_6 - h_5) - (h_7 - h_8)} \\ &= \frac{T_1 - T_8}{(T_2 - T_1) + 2(T_4 - T_3) - (T_7 - T_8)} \\ &= \frac{253 - 72.5}{(400.7 - 253) + 2(456.1 - 288) - (288 - 72.5)} = \mathbf{0.673} \end{aligned}$$

**11-121** An ideal vapor-compression refrigeration cycle with refrigerant-22 as the working fluid is considered. The evaporator is located inside the air handler of building. The hardware and the T-s diagram for this heat pump application are to be sketched. The COP of the unit and the ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant-22 data from the problem statement,

$$\left. \begin{array}{l} T_1 = -5^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -5^\circ\text{C} = 248.1 \text{ kJ/kg} \\ s_1 = s_g @ -5^\circ\text{C} = 0.9344 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1728 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 283.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1728 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1728 \text{ kPa} = 101 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 101 \text{ kJ/kg} \quad (\text{throttling})$$

(b) The COP of the heat pump is determined from its definition,

$$\text{COP}_{\text{HP}} = \frac{q_H}{w_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{283.7 - 101}{283.7 - 248.1} = \mathbf{5.13}$$

(c) An energy balance on the condenser gives

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = \dot{m}_a c_p \Delta T = \frac{\dot{V}_a}{v_a} c_p \Delta T$$

Rearranging, we obtain the ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler

$$\begin{aligned} \frac{\dot{V}_a}{\dot{m}_R} &= \frac{h_2 - h_3}{(1/v_a) c_p \Delta T} = \frac{(283.7 - 101) \text{ kJ/kg}}{(1/0.847 \text{ m}^3/\text{kg})(1.005 \text{ kJ/kg} \cdot \text{K})(20 \text{ K})} \\ &= 7.699 \text{ (m}^3 \text{ air/s)/(kg R22/s)} \\ &= \mathbf{462 \text{ (m}^3 \text{ air/min)/(kg R22/s)}} \end{aligned}$$

Note that the specific volume of air is obtained from ideal gas equation taking the pressure of air to be 101 kPa and using the room temperature of air ( $25^\circ\text{C} = 298 \text{ K}$ ) to be  $0.847 \text{ m}^3/\text{kg}$ .

**11-122** An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. Cooling water flows through the water jacket surrounding the condenser. To produce ice, potable water is supplied to the chiller section of the refrigeration cycle. The hardware and the T-s diagram for this refrigerant-ice making system are to be sketched. The mass flow rates of the refrigerant and the potable water are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant-134a data from the problem statement,

$$\left. \begin{array}{l} T_1 = 140 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 140 \text{ kPa} = 239.16 \text{ kJ/kg} \\ s_1 = s_g @ 140 \text{ kPa} = 0.94456 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 284.07 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1200 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1200 \text{ kPa} = 117.77 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 117.77 \text{ kJ/kg} \quad (\text{throttling})$$

(b) An energy balance on the condenser gives

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = \dot{m}_w c_p \Delta T$$

Solving for the mass flow rate of the refrigerant

$$\dot{m}_R = \frac{\dot{m}_w c_p \Delta T}{h_2 - h_3} = \frac{(200 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot \text{K})(10 \text{ K})}{(284.07 - 117.77) \text{ kJ/kg}} = \mathbf{50.3 \text{ kg/s}}$$

(c) An energy balance on the evaporator gives

$$\dot{Q}_L = \dot{m}_R (h_1 - h_4) = \dot{m}_w h_{if}$$

Solving for the mass flow rate of the potable water

$$\dot{m}_w = \frac{\dot{m}_R (h_1 - h_4)}{h_{if}} = \frac{(50.3 \text{ kg/s})(239.16 - 117.77) \text{ kJ/kg}}{333 \text{ kJ/kg}} = \mathbf{18.3 \text{ kg/s}}$$

**11-123** A vortex tube receives compressed air at 500 kPa and 300 K, and supplies 25 percent of it as cold air and the rest as hot air. The COP of the vortex tube is to be compared to that of a reversed Brayton cycle for the same pressure ratio; the exit temperature of the hot fluid stream and the COP are to be determined; and it is to be shown if this process violates the second law.

**Assumptions** **1** The vortex tube is adiabatic. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Steady operating conditions exist.

**Properties** The gas constant of air is 0.287 kJ/kg.K (Table A-1). The specific heat of air at room temperature is  $c_p = 1.005$  kJ/kg.K (Table A-2). The enthalpy of air at absolute temperature  $T$  can be expressed in terms of specific heats as  $h = c_p T$ .

**Analysis** (a) The COP of the vortex tube is much lower than the COP of a reversed Brayton cycle of the same pressure ratio since the vortex tube involves *vortices*, which are highly irreversible. Owing to this irreversibility, the minimum temperature that can be obtained by the vortex tube is not as low as the one that can be obtained by the reversed Brayton cycle.

(b) We take the vortex tube as the system. This is a steady flow system with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow energy balance equation for this system

$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  for a unit mass flow rate at the inlet ( $\dot{m}_1 = 1$  kg/s) can be expressed as

$$\begin{aligned}\dot{m}_1 h_1 &= \dot{m}_2 h_2 + \dot{m}_3 h_3 \\ \dot{m}_1 c_p T_1 &= \dot{m}_2 c_p T_2 + \dot{m}_3 c_p T_3 \\ 1c_p T_1 &= 0.25c_p T_2 + 0.75c_p T_3\end{aligned}$$

Canceling  $c_p$  and solving for  $T_3$  gives

$$\begin{aligned}T_3 &= \frac{T_1 - 0.25T_2}{0.75} \\ &= \frac{300 - 0.25 \times 278}{0.75} = \mathbf{307.3 \text{ K}}\end{aligned}$$

Therefore, the hot air stream will leave the vortex tube at an average temperature of 307.3 K.

(c) The entropy balance for this steady flow system  $\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = 0$  can be expressed as with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow entropy balance equation for this system for a unit mass flow rate at the inlet ( $\dot{m}_1 = 1$  kg/s) can be expressed

$$\begin{aligned}\dot{S}_{\text{gen}} &= \dot{S}_{\text{out}} - \dot{S}_{\text{in}} \\ &= \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_1 s_1 = \dot{m}_2 s_2 + \dot{m}_3 s_3 - (\dot{m}_2 + \dot{m}_3) s_1 \\ &= \dot{m}_2 (s_2 - s_1) + \dot{m}_3 (s_3 - s_1) \\ &= 0.25(s_2 - s_1) + 0.75(s_3 - s_1) \\ &= 0.25 \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) + 0.75 \left( c_p \ln \frac{T_3}{T_1} - R \ln \frac{P_3}{P_1} \right)\end{aligned}$$

Substituting the known quantities, the rate of entropy generation is determined to be

$$\begin{aligned}\dot{S}_{\text{gen}} &= 0.25 \left( (1.005 \text{ kJ/kg.K}) \ln \frac{278 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{500 \text{ kPa}} \right) \\ &\quad + 0.75 \left( (1.005 \text{ kJ/kg.K}) \ln \frac{307.3 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{500 \text{ kPa}} \right) \\ &= 0.461 \text{ kW/K} > 0\end{aligned}$$

which is a positive quantity. Therefore, this process **satisfies** the 2<sup>nd</sup> law of thermodynamics.

(d) For a unit mass flow rate at the inlet ( $\dot{m}_1 = 1 \text{ kg/s}$ ), the cooling rate and the power input to the compressor are determined to

$$\begin{aligned}\dot{Q}_{\text{cooling}} &= \dot{m}_c (h_1 - h_c) = \dot{m}_c c_p (T_1 - T_c) \\ &= (0.25 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(300 - 278)\text{K} = 5.53 \text{ kW} \\ \dot{W}_{\text{comp, in}} &= \frac{\dot{m}_0 R T_0}{(k-1)\eta_{\text{comp}}} \left[ \left( \frac{P_1}{P_0} \right)^{(k-1)/k} - 1 \right] \\ &= \frac{(1 \text{ kg/s})(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})}{(1.4-1)0.80} \left[ \left( \frac{500 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.4-1)/1.4} - 1 \right] = 157.1 \text{ kW}\end{aligned}$$

Then the COP of the vortex refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{comp, in}}} = \frac{5.53 \text{ kW}}{157.1 \text{ kW}} = \mathbf{0.035}$$

The COP of a Carnot refrigerator operating between the same temperature limits of 300 K and 278 K is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{278 \text{ K}}{(300 - 278) \text{ K}} = \mathbf{12.6}$$

**Discussion** Note that the COP of the vortex refrigerator is a small fraction of the COP of a Carnot refrigerator operating between the same temperature limits.

**11-124** A vortex tube receives compressed air at 600 kPa and 300 K, and supplies 25 percent of it as cold air and the rest as hot air. The COP of the vortex tube is to be compared to that of a reversed Brayton cycle for the same pressure ratio; the exit temperature of the hot fluid stream and the COP are to be determined; and it is to be shown if this process violates the second law.

**Assumptions** 1 The vortex tube is adiabatic. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Steady operating conditions exist.

**Properties** The gas constant of air is 0.287 kJ/kg.K (Table A-1). The specific heat of air at room temperature is  $c_p = 1.005$  kJ/kg.K (Table A-2). The enthalpy of air at absolute temperature  $T$  can be expressed in terms of specific heats as  $h = c_p T$ .

**Analysis** (a) The COP of the vortex tube is much lower than the COP of a reversed Brayton cycle of the same pressure ratio since the vortex tube involves *vortices*, which are highly irreversible. Owing to this irreversibility, the minimum temperature that can be obtained by the vortex tube is not as low as the one that can be obtained by the reversed Brayton cycle.

(b) We take the vortex tube as the system. This is a steady flow system with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow entropy balance equation for this system

$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  for a unit mass flow rate at the inlet ( $\dot{m}_1 = 1$  kg/s) can be expressed as

$$\begin{aligned}\dot{m}_1 h_1 &= \dot{m}_2 h_2 + \dot{m}_3 h_3 \\ \dot{m}_1 c_p T_1 &= \dot{m}_2 c_p T_2 + \dot{m}_3 c_p T_3 \\ 1c_p T_1 &= 0.25c_p T_2 + 0.75c_p T_3\end{aligned}$$

Canceling  $c_p$  and solving for  $T_3$  gives

$$\begin{aligned}T_3 &= \frac{T_1 - 0.25T_2}{0.75} \\ &= \frac{300 - 0.25 \times 278}{0.75} = \mathbf{307.3 \text{ K}}\end{aligned}$$

Therefore, the hot air stream will leave the vortex tube at an average temperature of 307.3 K.

(c) The entropy balance for this steady flow system  $\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = 0$  can be expressed as with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow energy balance equation for this system for a unit mass flow rate at the inlet ( $\dot{m}_1 = 1$  kg/s) can be expressed

$$\begin{aligned}\dot{S}_{\text{gen}} &= \dot{S}_{\text{out}} - \dot{S}_{\text{in}} \\ &= \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_1 s_1 = \dot{m}_2 s_2 + \dot{m}_3 s_3 - (\dot{m}_2 + \dot{m}_3) s_1 \\ &= \dot{m}_2 (s_2 - s_1) + \dot{m}_3 (s_3 - s_1) \\ &= 0.25(s_2 - s_1) + 0.75(s_3 - s_1) \\ &= 0.25 \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) + 0.75 \left( c_p \ln \frac{T_3}{T_1} - R \ln \frac{P_3}{P_1} \right)\end{aligned}$$

Substituting the known quantities, the rate of entropy generation is determined to be

$$\begin{aligned}\dot{S}_{\text{gen}} &= 0.25 \left( (1.005 \text{ kJ/kg.K}) \ln \frac{278 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{600 \text{ kPa}} \right) \\ &\quad + 0.75 \left( (1.005 \text{ kJ/kg.K}) \ln \frac{307.3 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{600 \text{ kPa}} \right) \\ &= 0.513 \text{ kW/K} > 0\end{aligned}$$

which is a positive quantity. Therefore, this process **satisfies** the 2<sup>nd</sup> law of thermodynamics.

(d) For a unit mass flow rate at the inlet ( $\dot{m}_1 = 1 \text{ kg/s}$ ), the cooling rate and the power input to the compressor are determined to

$$\begin{aligned}\dot{Q}_{\text{cooling}} &= \dot{m}_c (h_1 - h_c) = \dot{m}_c c_p (T_1 - T_c) \\ &= (0.25 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(300 - 278)\text{K} = 5.53 \text{ kW} \\ \dot{W}_{\text{comp, in}} &= \frac{\dot{m}_0 R T_0}{(k-1)\eta_{\text{comp}}} \left[ \left( \frac{P_1}{P_0} \right)^{(k-1)/k} - 1 \right] \\ &= \frac{(1 \text{ kg/s})(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})}{(1.4-1)0.80} \left[ \left( \frac{600 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.4-1)/1.4} - 1 \right] = 179.9 \text{ kW}\end{aligned}$$

Then the COP of the vortex refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{comp, in}}} = \frac{5.53 \text{ kW}}{179.9 \text{ kW}} = \mathbf{0.031}$$

The COP of a Carnot refrigerator operating between the same temperature limits of 300 K and 278 K is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{278 \text{ K}}{(300 - 278) \text{ K}} = \mathbf{12.6}$$

**Discussion** Note that the COP of the vortex refrigerator is a small fraction of the COP of a Carnot refrigerator operating between the same temperature limits.

**11-125 EES** The effect of the evaporator pressure on the COP of an ideal vapor-compression refrigeration cycle with R-134a as the working fluid is to be investigated.

## Fundamentals of Engineering (FE) Exam Problems

**11-127** Consider a heat pump that operates on the reversed Carnot cycle with R-134a as the working fluid executed under the saturation dome between the pressure limits of 140 kPa and 800 kPa. R-134a changes from saturated vapor to saturated liquid during the heat rejection process. The net work input for this cycle is

- (a) 28 kJ/kg      (b) 34 kJ/kg      (c) 49 kJ/kg      (d) 144 kJ/kg      (e) 275 kJ/kg

*Answer* (a) 28 kJ/kg

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=800 "kPa"
P2=140 "kPa"
h_fg=ENTHALPY(R134a,x=1,P=P1)-ENTHALPY(R134a,x=0,P=P1)
TH=TEMPERATURE(R134a,x=0,P=P1)+273
TL=TEMPERATURE(R134a,x=0,P=P2)+273
q_H=h_fg
COP=TH/(TH-TL)
w_net=q_H/COP
```

**"Some Wrong Solutions with Common Mistakes:"**

W1\_work = q\_H/COP1; COP1=TL/(TH-TL) **"Using COP of refrigerator"**

W2\_work = q\_H/COP2; COP2=(TH-273)/(TH-TL) **"Using C instead of K"**

W3\_work = h\_fg3/COP; h\_fg3= ENTHALPY(R134a,x=1,P=P2)-ENTHALPY(R134a,x=0,P=P2)

**"Using h\_fg at P2"**

W4\_work = q\_H\*TL/TH **"Using the wrong relation"**

**11-128** A refrigerator removes heat from a refrigerated space at  $-5^{\circ}\text{C}$  at a rate of  $0.35\text{ kJ/s}$  and rejects it to an environment at  $20^{\circ}\text{C}$ . The minimum required power input is

- (a) 30 W                      (b) 33 W                      (c) 56 W                      (d) 124 W                      (e) 350 W

Answer (b) 33 W

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
TH=20+273
TL=-5+273
Q_L=0.35 "kJ/s"
COP_max=TL/(TH-TL)
w_min=Q_L/COP_max
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_work = Q_L/COP1; COP1=TH/(TH-TL) "Using COP of heat pump"
W2_work = Q_L/COP2; COP2=(TH-273)/(TH-TL) "Using C instead of K"
W3_work = Q_L*TL/TH "Using the wrong relation"
W4_work = Q_L "Taking the rate of refrigeration as power input"
```

**11-129** A refrigerator operates on the ideal vapor compression refrigeration cycle with R-134a as the working fluid between the pressure limits of 120 kPa and 800 kPa. If the rate of heat removal from the refrigerated space is 32 kJ/s, the mass flow rate of the refrigerant is

- (a) 0.19 kg/s      (b) 0.15 kg/s      (c) 0.23 kg/s      (d) 0.28 kg/s      (e) 0.81 kg/s

*Answer* (c) 0.23 kg/s

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=120 "kPa"
P2=800 "kPa"
P3=P2
P4=P1
s2=s1
Q_refrig=32 "kJ/s"
m=Q_refrig/(h1-h4)

h4=h3
x4=QUALITY(R134a,h=h4,P=P4)
liquid=1-x4
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_liquid = x4 "Taking quality as liquid content"
W2_liquid = 0 "Assuming superheated vapor"
W3_liquid = 1-x4s; x4s=QUALITY(R134a,s=s3,P=P4) "Assuming isentropic expansion"
s3=ENTROPY(R134a,x=0,P=P3)
```

**11-132** Consider a heat pump that operates on the ideal vapor compression refrigeration cycle with R-134a as the working fluid between the pressure limits of 0.32 MPa and 1.2 MPa. The coefficient of performance of this heat pump is

- (a) 0.17                      (b) 1.2                      (c) 3.1                      (d) 4.9                      (e) 5.9

*Answer* (e) 5.9

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=320 "kPa"
P2=1200 "kPa"
P3=P2
P4=P1
s2=s1
h1=ENTHALPY(R134a,x=1,P=P1)
s1=ENTROPY(R134a,x=1,P=P1)
h2=ENTHALPY(R134a,s=s2,P=P2)
h3=ENTHALPY(R134a,x=0,P=P3)
h4=h3
COP_HP=qH/Win
Win=h2-h1
qH=h2-h3
```

**"Some Wrong Solutions with Common Mistakes:"**

W1\_COP = (h1-h4)/(h2-h1) "COP of refrigerator"

W2\_COP = (h1-h4)/(h2-h3) "Using wrong enthalpies, QL/QH"

W3\_COP = (h22-h3)/(h22-h1); h22=ENTHALPY(R134a,x=1,P=P2) "Using wrong enthalpy h2 (hg at P2)"

**11-133** An ideal gas refrigeration cycle using air as the working fluid operates between the pressure limits of 80 kPa and 280 kPa. Air is cooled to 35°C before entering the turbine. The lowest temperature of this cycle is

- (a) -58°C                      (b) -26°C                      (c) 0°C                      (d) 11°C                      (e) 24°C

*Answer* (a) -58°C

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.4
P1= 80 "kPa"
P2=280 "kPa"
T3=35+273 "K"
"Minimum temperature is the turbine exit temperature"
T4=T3*(P1/P2)^((k-1)/k) - 273
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Tmin = (T3-273)*(P1/P2)^((k-1)/k) "Using C instead of K"
W2_Tmin = T3*(P1/P2)^((k-1)) - 273 "Using wrong exponent"
W3_Tmin = T3*(P1/P2)^k - 273 "Using wrong exponent"
```

**11-134** Consider an ideal gas refrigeration cycle using helium as the working fluid. Helium enters the compressor at 100 kPa and  $-10^{\circ}\text{C}$  and is compressed to 250 kPa. Helium is then cooled to  $20^{\circ}\text{C}$  before it enters the turbine. For a mass flow rate of 0.2 kg/s, the net power input required is

- (a) 9.3 kW                      (b) 27.6 kW                      (c) 48.8 kW                      (d) 93.5 kW                      (e) 119 kW

Answer (b) 27.6 kW

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.667
Cp=5.1926 "kJ/kg.K"
P1= 100 "kPa"
T1=-10+273 "K"
P2=250 "kPa"
T3=20+273 "K"
m=0.2 "kg/s"
"Mimimum temperature is the turbine exit temperature"
T2=T1*(P2/P1)^((k-1)/k)
T4=T3*(P1/P2)^((k-1)/k)
W_netin=m*Cp*((T2-T1)-(T3-T4))
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Win = m*Cp*((T22-T1)-(T3-T44)); T22=T1*P2/P1; T44=T3*P1/P2 "Using wrong relations
for temps"
```

```
W2_Win = m*Cp*(T2-T1) "Ignoring turbine work"
```

```
W3_Win=m*1.005*((T2B-T1)-(T3-T4B)); T2B=T1*(P2/P1)^((kB-1)/kB); T4B=T3*(P1/P2)^((kB-
1)/kB); kB=1.4 "Using air properties"
```

```
W4_Win=m*Cp*((T2A-(T1-273))-(T3-273-T4A)); T2A=(T1-273)*(P2/P1)^((k-1)/k); T4A=(T3-
273)*(P1/P2)^((k-1)/k) "Using C instead of K"
```

**11-135** An absorption air-conditioning system is to remove heat from the conditioned space at 20°C at a rate of 150 kJ/s while operating in an environment at 35°C. Heat is to be supplied from a geothermal source at 140°C. The minimum rate of heat supply required is

- (a) 86 kJ/s                      (b) 21 kJ/s                      (c) 30 kJ/s                      (d) 61 kJ/s                      (e) 150 kJ/s

*Answer* (c) 30 kJ/s

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
TL=20+273 "K"
Q_refrig=150 "kJ/s"
To=35+273 "K"
Ts=140+273 "K"
COP_max=(1-To/Ts)*(TL/(To-TL))
Q_in=Q_refrig/COP_max
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Qin = Q_refrig "Taking COP = 1"
W2_Qin = Q_refrig/COP2; COP2=TL/(Ts-TL) "Wrong COP expression"
W3_Qin = Q_refrig/COP3; COP3=(1-To/Ts)*(Ts/(To-TL)) "Wrong COP expression, COP_HP"
W4_Qin = Q_refrig*COP_max "Multiplying by COP instead of dividing"
```

**11-136** Consider a refrigerator that operates on the vapor compression refrigeration cycle with R-134a as the working fluid. The refrigerant enters the compressor as saturated vapor at 160 kPa, and exits at 800 kPa and 50°C, and leaves the condenser as saturated liquid at 800 kPa. The coefficient of performance of this refrigerator is

- (a) 2.6                      (b) 1.0                      (c) 4.2                      (d) 3.2                      (e) 4.4

Answer (d) 3.2

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=160 "kPa"
P2=800 "kPa"
T2=50 "C"
P3=P2
P4=P1

```
W1_COP = (h2-h3)/(h2-h1) "COP of heat pump"
W2_COP = (h1-h4)/(h2-h3) "Using wrong enthalpies, QL/QH"
W3_COP = (h1-h4)/(h2s-h1); h2s=ENTHALPY(R134a,s=s1,P=P2) "Assuming isentropic compression"
```

## 11-137 ... 11-145 Design and Essay Problems

# Chapter 12

## THERMODYNAMIC PROPERTY RELATIONS

### Partial Derivatives and Associated Relations

12-1C

**12-2C** For functions that depend on one variable, they are identical. For functions that depend on two or more variable, the partial differential represents the change in the function with one of the variables as the other variables are held constant. The ordinary differential for such functions represents the total change as a result of differential changes in all variables.

**12-3C** (a)  $(\partial x)_y = dx$  ; (b)  $(\partial z)_y \leq dz$ ; and (c)  $dz = (\partial z)_x + (\partial z)_y$

**12-4C** Yes.

**12-5C** Yes.

**12-6** Air at a specified temperature and specific volume is considered. The changes in pressure corresponding to a certain increase of different properties are to be determined.

**Assumptions** Air is an ideal gas.

**Properties** The gas constant of air is  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$  (Table A-1).

**Analysis** An ideal gas equation can be expressed as  $P = RT/v$ . Noting that  $R$  is a constant and  $P = P(T, v)$ ,

$$dP = \left( \frac{\partial P}{\partial T} \right)_v dT + \left( \frac{\partial P}{\partial v} \right)_T dv = \frac{RdT}{v} - \frac{RTdv}{v^2}$$

(a) The change in  $T$  can be expressed as  $dT \cong \Delta T = 400 \times 0.01 = 4.0 \text{ K}$ . At  $v = \text{constant}$ ,

$$(dP)_v = \frac{RdT}{v} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(4.0 \text{ K})}{0.90 \text{ m}^3/\text{kg}} = \mathbf{1.276 \text{ kPa}}$$

(b) The change in  $v$  can be expressed as  $dv \cong \Delta v = 0.90 \times 0.01 = 0.009 \text{ m}^3/\text{kg}$ . At  $T = \text{constant}$ ,

$$(dP)_T = -\frac{RTdv}{v^2} = -\frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(400 \text{ K})(0.009 \text{ m}^3/\text{kg})}{(0.90 \text{ m}^3/\text{kg})^2} = \mathbf{-1.276 \text{ kPa}}$$

(c) When both  $v$  and  $T$  increases by 1%, the change in  $P$  becomes

$$dP = (dP)_v + (dP)_T = 1.276 + (-1.276) = \mathbf{0}$$

Thus the changes in  $T$  and  $v$  balance each other.

**12-7** Helium at a specified temperature and specific volume is considered. The changes in pressure corresponding to a certain increase of different properties are to be determined.

**Assumptions** Helium is an ideal gas

**Properties** The gas constant of helium is  $R = 2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$  (Table A-1).

**Analysis** An ideal gas equation can be expressed as  $P = RT/v$ . Noting that  $R$  is a constant and  $P = P(T, v)$ ,

$$dP = \left( \frac{\partial P}{\partial T} \right)_v dT + \left( \frac{\partial P}{\partial v} \right)_T dv = \frac{RdT}{v} - \frac{RTdv}{v^2}$$

(a) The change in  $T$  can be expressed as  $dT \cong \Delta T = 400 \times 0.01 = 4.0 \text{ K}$ . At  $v = \text{constant}$ ,

$$(dP)_v = \frac{RdT}{v} = \frac{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(4.0 \text{ K})}{0.90 \text{ m}^3/\text{kg}} = \mathbf{9.231 \text{ kPa}}$$

(b) The change in  $v$  can be expressed as  $dv \cong \Delta v = 0.90 \times 0.01 = 0.009 \text{ m}^3/\text{kg}$ . At  $T = \text{constant}$ ,

$$(dP)_T = -\frac{RTdv}{v^2} = -\frac{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(400 \text{ K})(0.009 \text{ m}^3/\text{kg})}{(0.90 \text{ m}^3/\text{kg})^2} = \mathbf{-9.231 \text{ kPa}}$$

(c) When both  $v$  and  $T$  increases by 1%, the change in  $P$  becomes

$$dP = (dP)_v + (dP)_T = 9.231 + (-9.231) = \mathbf{0}$$

Thus the changes in  $T$  and  $v$  balance each other.

**12-8** It is to be proven for an ideal gas that the  $P = \text{constant}$  lines on a  $T$ - $\nu$  diagram are straight lines and that the high pressure lines are steeper than the low-pressure lines.

**Analysis** (a) For an ideal gas  $P\nu = RT$  or  $T = P\nu/R$ . Taking the partial derivative of  $T$  with respect to  $\nu$  holding  $P$  constant yields

$$\left(\frac{\partial T}{\partial \nu}\right)_P = \frac{P}{R}$$

which remains constant at  $P = \text{constant}$ . Thus the derivative  $(\partial T/\partial \nu)_P$ , which represents the slope of the  $P = \text{const.}$  lines on a  $T$ - $\nu$  diagram, remains constant. That is, the  $P = \text{const.}$  lines are straight lines on a  $T$ - $\nu$  diagram.

(b) The slope of the  $P = \text{const.}$  lines on a  $T$ - $\nu$  diagram is equal to  $P/R$ , which is proportional to  $P$ . Therefore, the high pressure lines are steeper than low pressure lines on the  $T$ - $\nu$  diagram.

**12-9** A relation is to be derived for the slope of the  $\nu = \text{constant}$  lines on a  $T$ - $P$  diagram for a gas that obeys the van der Waals equation of state.

**Analysis** The van der Waals equation of state can be expressed as

$$T = \frac{1}{R} \left( P + \frac{a}{\nu^2} \right) (\nu - b)$$

Taking the derivative of  $T$  with respect to  $P$  holding  $\nu$  constant,

$$\left(\frac{\partial T}{\partial P}\right)_\nu = \frac{1}{R} (1 + 0)(\nu - b) = \frac{\nu - b}{R}$$

which is the slope of the  $\nu = \text{constant}$  lines on a  $T$ - $P$  diagram.

**12-10** Nitrogen gas at a specified state is considered. The  $c_p$  and  $c_v$  of the nitrogen are to be determined using Table A-18, and to be compared to the values listed in Table A-2b.

**Analysis** The  $c_p$  and  $c_v$  of ideal gases depends on temperature only, and are expressed as  $c_p(T) = dh(T)/dT$  and  $c_v(T) = du(T)/dT$ . Approximating the differentials as differences about 400 K, the  $c_p$  and  $c_v$  values are determined to be

$$\begin{aligned} c_p(400 \text{ K}) &= \left( \frac{dh(T)}{dT} \right)_{T=400 \text{ K}} \cong \left( \frac{\Delta h(T)}{\Delta T} \right)_{T \cong 400 \text{ K}} \\ &= \frac{h(410 \text{ K}) - h(390 \text{ K})}{(410 - 390) \text{ K}} \\ &= \frac{(11,932 - 11,347) \text{ kJ/kg}}{(410 - 390) \text{ K}} \\ &= \mathbf{1.045 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

(Compare: Table A-2b at 400 K  $\rightarrow c_p = 1.044 \text{ kJ/kg} \cdot \text{K}$ )

$$\begin{aligned} c_v(400 \text{ K}) &= \left( \frac{du(T)}{dT} \right)_{T=400 \text{ K}} \cong \left( \frac{\Delta u(T)}{\Delta T} \right)_{T \cong 400 \text{ K}} \\ &= \frac{u(410 \text{ K}) - u(390 \text{ K})}{(410 - 390) \text{ K}} \\ &= \frac{(8,523 - 8,104) \text{ kJ/kg}}{(410 - 390) \text{ K}} = \mathbf{0.748 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

(Compare: Table A-2b at 400 K  $\rightarrow c_v = 0.747 \text{ kJ/kg} \cdot \text{K}$ )

**12-11E** Nitrogen gas at a specified state is considered. The  $c_p$  and  $c_v$  of the nitrogen are to be determined using Table A-18E, and to be compared to the values listed in Table A-2Eb.

**Analysis** The  $c_p$  and  $c_v$  of ideal gases depends on temperature only, and are expressed as  $c_p(T) = dh(T)/dT$  and  $c_v(T) = du(T)/dT$ . Approximating the differentials as differences about 600 R, the  $c_p$  and  $c_v$  values are determined to be

$$\begin{aligned} c_p(600 \text{ R}) &= \left( \frac{dh(T)}{dT} \right)_{T=600 \text{ R}} \cong \left( \frac{\Delta h(T)}{\Delta T} \right)_{T \cong 600 \text{ R}} \\ &= \frac{h(620 \text{ R}) - h(580 \text{ R})}{(620 - 580) \text{ R}} \\ &= \frac{(4,307.1 - 4,028.7)/28.0 \text{ Btu/lbm}}{(620 - 580) \text{ R}} = \mathbf{0.249 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(Compare: Table A-2Eb at 600 R  $\rightarrow c_p = 0.248 \text{ Btu/lbm} \cdot \text{R}$  )

$$\begin{aligned} c_v(600 \text{ R}) &= \left( \frac{du(T)}{dT} \right)_{T=600 \text{ R}} \cong \left( \frac{\Delta u(T)}{\Delta T} \right)_{T \cong 600 \text{ R}} \\ &= \frac{u(620 \text{ R}) - u(580 \text{ R})}{(620 - 580) \text{ R}} \\ &= \frac{(3,075.9 - 2,876.9)/28.0 \text{ Btu/lbm}}{(620 - 580) \text{ R}} = \mathbf{0.178 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(Compare: Table A-2Eb at 600 R  $\rightarrow c_v = 0.178 \text{ Btu/lbm} \cdot \text{R}$  )

**12-12** The state of an ideal gas is altered slightly. The change in the specific volume of the gas is to be determined using differential relations and the ideal-gas relation at each state.

**Assumptions** The gas is air and air is an ideal gas.

**Properties** The gas constant of air is  $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$  (Table A-1).

**Analysis** (a) The changes in  $T$  and  $P$  can be expressed as

$$dT \cong \Delta T = (404 - 400)\text{K} = 4 \text{ K}$$

$$dP \cong \Delta P = (96 - 100)\text{kPa} = -4 \text{ kPa}$$

The ideal gas relation  $P\nu = RT$  can be expressed as  $\nu = RT/P$ . Note that  $R$  is a constant and  $\nu = \nu(T, P)$ . Applying the total differential relation and using average values for  $T$  and  $P$ ,

$$\begin{aligned} d\nu &= \left( \frac{\partial \nu}{\partial T} \right)_P dT + \left( \frac{\partial \nu}{\partial P} \right)_T dP = \frac{RdT}{P} - \frac{RTdP}{P^2} \\ &= (0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}) \left( \frac{4 \text{ K}}{98 \text{ kPa}} - \frac{(402 \text{ K})(-4 \text{ kPa})}{(98 \text{ kPa})^2} \right) \\ &= (0.0117 \text{ m}^3/\text{kg}) + (0.04805 \text{ m}^3/\text{kg}) = \mathbf{0.0598 \text{ m}^3/\text{kg}} \end{aligned}$$

(b) Using the ideal gas relation at each state,

$$\begin{aligned} \nu_1 &= \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(400 \text{ K})}{100 \text{ kPa}} = 1.1480 \text{ m}^3/\text{kg} \\ \nu_2 &= \frac{RT_2}{P_2} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(404 \text{ K})}{96 \text{ kPa}} = 1.2078 \text{ m}^3/\text{kg} \end{aligned}$$

Thus,

$$\Delta \nu = \nu_2 - \nu_1 = 1.2078 - 1.1480 = \mathbf{0.0598 \text{ m}^3/\text{kg}}$$

The two results are identical.

**12-13** Using the equation of state  $P(\nu - a) = RT$ , the cyclic relation, and the reciprocity relation at constant  $\nu$  are to be verified.

**Analysis** (a) This equation of state involves three variables  $P$ ,  $\nu$ , and  $T$ . Any two of these can be taken as the independent variables, with the remaining one being the dependent variable. Replacing  $x$ ,  $y$ , and  $z$  by  $P$ ,  $\nu$ , and  $T$ , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu = -1$$

where

$$\begin{aligned} P &= \frac{RT}{\nu - a} \longrightarrow \left(\frac{\partial P}{\partial \nu}\right)_T = \frac{-RT}{(\nu - a)^2} = -\frac{P}{\nu - a} \\ \nu &= \frac{RT}{P} + a \longrightarrow \left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P} \\ T &= \frac{P(\nu - a)}{R} \longrightarrow \left(\frac{\partial T}{\partial P}\right)_\nu = \frac{\nu - a}{R} \end{aligned}$$

Substituting,

$$\left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu = \left(-\frac{P}{\nu - a}\right) \left(\frac{R}{P}\right) \left(\frac{\nu - a}{R}\right) = -1$$

which is the desired result.

(b) The reciprocity rule for this gas at  $\nu = \text{constant}$  can be expressed as

$$\begin{aligned} \left(\frac{\partial P}{\partial T}\right)_\nu &= \frac{1}{(\partial T / \partial P)_\nu} \\ T &= \frac{P(\nu - a)}{R} \longrightarrow \left(\frac{\partial T}{\partial P}\right)_\nu = \frac{\nu - a}{R} \\ P &= \frac{RT}{\nu - a} \longrightarrow \left(\frac{\partial P}{\partial T}\right)_\nu = \frac{R}{\nu - a} \end{aligned}$$

We observe that the first differential is the inverse of the second one. Thus the proof is complete.

## The Maxwell Relations

**12-14** The validity of the last Maxwell relation for refrigerant-134a at a specified state is to be verified.

**Analysis** We do not have exact analytical property relations for refrigerant-134a, and thus we need to replace the differential quantities in the last Maxwell relation with the corresponding finite quantities. Using property values from the tables about the specified state,

$$\begin{aligned} \left( \frac{\partial s}{\partial P} \right)_T &\stackrel{?}{=} - \left( \frac{\partial v}{\partial T} \right)_P \\ \left( \frac{\Delta s}{\Delta P} \right)_{T=80^\circ\text{C}} &\stackrel{?}{\cong} - \left( \frac{\Delta v}{\Delta T} \right)_{P=1200\text{kPa}} \\ \left( \frac{s_{1400\text{ kPa}} - s_{1000\text{ kPa}}}{(1400 - 1000)\text{kPa}} \right)_{T=80^\circ\text{C}} &\stackrel{?}{\cong} - \left( \frac{v_{100^\circ\text{C}} - v_{60^\circ\text{C}}}{(100 - 60)^\circ\text{C}} \right)_{P=1200\text{kPa}} \\ \frac{(1.0056 - 1.0458)\text{kJ/kg} \cdot \text{K}}{(1400 - 1000)\text{kPa}} &\stackrel{?}{\cong} - \frac{(0.022442 - 0.018404)\text{m}^3/\text{kg}}{(100 - 60)^\circ\text{C}} \\ &\cong -1.005 \times 10^{-4} \text{ m}^3/\text{kg} \cdot \text{K} \cong -1.0095 \times 10^{-4} \text{ m}^3/\text{kg} \cdot \text{K} \end{aligned}$$

since  $\text{kJ} \equiv \text{kPa} \cdot \text{m}^3$ , and  $\text{K} \equiv ^\circ\text{C}$  for temperature differences. Thus the last Maxwell relation is satisfied.

**12-15 EES** Problem 12-14 is reconsidered. The validity of the last Maxwell relation for refrigerant 134a at the specified state is to be verified.

**Analysis** The problem is solved using EES, and the solution is given below.

**12-16E** The validity of the last Maxwell relation for steam at a specified state is to be verified.

**Analysis** We do not have exact analytical property relations for steam, and thus we need to replace the differential quantities in the last Maxwell relation with the corresponding finite quantities. Using property values from the tables about the specified state,

$$\begin{aligned} \left( \frac{\partial s}{\partial P} \right)_T &\stackrel{?}{=} - \left( \frac{\partial \nu}{\partial T} \right)_P \\ \left( \frac{\Delta s}{\Delta P} \right)_{T=800^\circ\text{F}} &\stackrel{?}{\cong} - \left( \frac{\Delta \nu}{\Delta T} \right)_{P=400\text{psia}} \\ \left( \frac{s_{450\text{ psia}} - s_{350\text{ psia}}}{(450 - 350)\text{psia}} \right)_{T=800^\circ\text{F}} &\stackrel{?}{\cong} - \left( \frac{\nu_{900^\circ\text{F}} - \nu_{700^\circ\text{F}}}{(900 - 700)^\circ\text{F}} \right)_{P=400\text{psia}} \\ \frac{(1.6706 - 1.7009)\text{Btu/lbm} \cdot \text{R}}{(450 - 350)\text{psia}} &\stackrel{?}{\cong} - \frac{(1.9777 - 1.6507)\text{ft}^3/\text{lbm}}{(900 - 700)^\circ\text{F}} \\ -1.639 \times 10^{-3} \text{ ft}^3/\text{lbm} \cdot \text{R} &\cong -1.635 \times 10^{-3} \text{ ft}^3/\text{lbm} \cdot \text{R} \end{aligned}$$

since  $1 \text{ Btu} \equiv 5.4039 \text{ psia} \cdot \text{ft}^3$ , and  $\text{R} \equiv ^\circ\text{F}$  for temperature differences. Thus the fourth Maxwell relation is satisfied.

**12-17** Using the Maxwell relations, a relation for  $(\partial s / \partial P)_T$  for a gas whose equation of state is  $P(\nu - b) = RT$  is to be obtained.

**Analysis** This equation of state can be expressed as  $\nu = \frac{RT}{P} + b$ . Then,

$$\left( \frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

From the fourth Maxwell relation,

$$\left( \frac{\partial s}{\partial P} \right)_T = - \left( \frac{\partial \nu}{\partial T} \right)_P = - \frac{R}{P}$$

**12-18** Using the Maxwell relations, a relation for  $(\partial s / \partial \nu)_T$  for a gas whose equation of state is  $(P - a/\nu^2)(\nu - b) = RT$  is to be obtained.

**Analysis** This equation of state can be expressed as  $P = \frac{RT}{\nu - b} + \frac{a}{\nu^2}$ . Then,

$$\left( \frac{\partial P}{\partial T} \right)_{\nu} = \frac{R}{\nu - b}$$

From the third Maxwell relation,

$$\left( \frac{\partial s}{\partial \nu} \right)_T = \left( \frac{\partial P}{\partial T} \right)_{\nu} = \frac{R}{\nu - b}$$

**12-19** Using the Maxwell relations and the ideal-gas equation of state, a relation for  $(\partial s / \partial \nu)_T$  for an ideal gas is to be obtained.

**Analysis** The ideal gas equation of state can be expressed as  $P = \frac{RT}{\nu}$ . Then,

$$\left( \frac{\partial P}{\partial T} \right)_{\nu} = \frac{R}{\nu}$$

From the third Maxwell relation,

$$\left( \frac{\partial s}{\partial \nu} \right)_T = \left( \frac{\partial P}{\partial T} \right)_{\nu} = \frac{R}{\nu}$$

**12-20** It is to be proven that  $\left(\frac{\partial P}{\partial T}\right)_s = \frac{k}{k-1} \left(\frac{\partial P}{\partial T}\right)_v$

**Analysis** Using the definition of  $c_v$ ,

$$c_v = T \left( \frac{\partial s}{\partial T} \right)_v = T \left( \frac{\partial s}{\partial P} \right)_v \left( \frac{\partial P}{\partial T} \right)_v$$

Substituting the first Maxwell relation  $\left( \frac{\partial s}{\partial P} \right)_v = - \left( \frac{\partial v}{\partial T} \right)_s$ ,

$$c_v = -T \left( \frac{\partial v}{\partial T} \right)_s \left( \frac{\partial P}{\partial T} \right)_v$$

Using the definition of  $c_p$ ,

$$c_p = T \left( \frac{\partial s}{\partial T} \right)_p = T \left( \frac{\partial s}{\partial v} \right)_p \left( \frac{\partial v}{\partial T} \right)_p$$

Substituting the second Maxwell relation  $\left( \frac{\partial s}{\partial v} \right)_p = \left( \frac{\partial P}{\partial T} \right)_s$ ,

$$c_p = T \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial v}{\partial T} \right)_p$$

From Eq. 12-46,

$$c_p - c_v = -T \left( \frac{\partial v}{\partial T} \right)_p^2 \left( \frac{\partial P}{\partial v} \right)_T$$

Also,

$$\frac{k}{k-1} = \frac{c_p}{c_p - c_v}$$

Then,

$$\frac{k}{k-1} = - \frac{\left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial v}{\partial T} \right)_p}{\left( \frac{\partial v}{\partial T} \right)_p^2 \left( \frac{\partial P}{\partial v} \right)_T} = - \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial T}{\partial v} \right)_p \left( \frac{\partial v}{\partial P} \right)_T$$

Substituting this into the original equation in the problem statement produces

$$\left( \frac{\partial P}{\partial T} \right)_s = - \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial T}{\partial v} \right)_p \left( \frac{\partial v}{\partial P} \right)_T \left( \frac{\partial P}{\partial T} \right)_v$$

But, according to the cyclic relation, the last three terms are equal to  $-1$ . Then,

$$\left( \frac{\partial P}{\partial T} \right)_s = \left( \frac{\partial P}{\partial T} \right)_s$$

**12-21** It is to be shown how  $T$ ,  $\nu$ ,  $u$ ,  $a$ , and  $g$  could be evaluated from the thermodynamic function  $h = h(s, P)$ .

**Analysis** Forming the differential of the given expression for  $h$  produces

$$dh = \left( \frac{\partial h}{\partial s} \right)_P ds + \left( \frac{\partial h}{\partial P} \right)_s dP$$

Solving the  $dh$  Gibbs equation gives

$$dh = Tds + \nu dP$$

Comparing the coefficient of these two expressions

$$T = \left( \frac{\partial h}{\partial s} \right)_P$$

$$\nu = \left( \frac{\partial h}{\partial P} \right)_s$$

both of which can be evaluated for a given  $P$  and  $s$ .

From the definition of the enthalpy,

$$u = h - P\nu = h - P \left( \frac{\partial h}{\partial P} \right)_s$$

Similarly, the definition of the Helmholtz function,

$$a = u - Ts = h - P \left( \frac{\partial h}{\partial P} \right)_s - s \left( \frac{\partial h}{\partial s} \right)_P$$

while the definition of the Gibbs function gives

$$q = h - Ts = h - s \left( \frac{\partial h}{\partial s} \right)_P$$

All of these can be evaluated for a given  $P$  and  $s$  and the fundamental  $h(s, P)$  equation.

## The Clapeyron Equation

**12-22C** It enables us to determine the enthalpy of vaporization from  $h_{fg}$  at a given temperature from the  $P$ ,  $v$ ,  $T$  data alone.

**12-23C** It is assumed that  $u_{fg} \cong v_g \cong RT/P$ , and  $h_{fg} \cong$  constant for small temperature intervals.

**12-24** Using the Clapeyron equation, the enthalpy of vaporization of steam at a specified pressure is to be estimated and to be compared to the tabulated data.

**Analysis** From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T v_{fg} \left( \frac{dP}{dT} \right)_{\text{sat}} \\
 &\cong T (v_g - v_f)_{@300 \text{ kPa}} \left( \frac{\Delta P}{\Delta T} \right)_{\text{sat}, 300 \text{ kPa}} \\
 &= T_{\text{sat}@300 \text{ kPa}} (v_g - v_f)_{@300 \text{ kPa}} \left( \frac{(325 - 275) \text{ kPa}}{T_{\text{sat}@325 \text{ kPa}} - T_{\text{sat}@275 \text{ kPa}}} \right) \\
 &= (133.52 + 273.15 \text{ K}) (0.60582 - 0.001073 \text{ m}^3/\text{kg}) \left( \frac{50 \text{ kPa}}{(136.27 - 130.58)^\circ\text{C}} \right) \\
 &= \mathbf{2159.9 \text{ kJ/kg}}
 \end{aligned}$$

The tabulated value of  $h_{fg}$  at 300 kPa is **2163.5 kJ/kg**.

**12-25** The  $h_{fg}$  and  $s_{fg}$  of steam at a specified temperature are to be calculated using the Clapeyron equation and to be compared to the tabulated data.

**Analysis** From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T \nu_{fg} \left( \frac{dP}{dT} \right)_{\text{sat}} \\
 &\cong T(\nu_g - \nu_f)_{@120^\circ\text{C}} \left( \frac{\Delta P}{\Delta T} \right)_{\text{sat}, 120^\circ\text{C}} \\
 &= T(\nu_g - \nu_f)_{@120^\circ\text{C}} \left( \frac{P_{\text{sat}@125^\circ\text{C}} - P_{\text{sat}@115^\circ\text{C}}}{125^\circ\text{C} - 115^\circ\text{C}} \right) \\
 &= (120 + 273.15 \text{ K})(0.89133 - 0.001060 \text{ m}^3/\text{kg}) \left( \frac{(232.23 - 169.18) \text{ kPa}}{10 \text{ K}} \right) \\
 &= \mathbf{2206.8 \text{ kJ/kg}}
 \end{aligned}$$

Also,

$$s_{fg} = \frac{h_{fg}}{T} = \frac{2206.8 \text{ kJ/kg}}{(120 + 273.15) \text{ K}} = \mathbf{5.6131 \text{ kJ/kg} \cdot \text{K}}$$

The tabulated values at  $120^\circ\text{C}$  are  $h_{fg} = \mathbf{2202.1 \text{ kJ/kg}}$  and  $s_{fg} = \mathbf{5.6013 \text{ kJ/kg} \cdot \text{K}}$ .

**12-26E** [Also solved by EES on enclosed CD] The  $h_{fg}$  of refrigerant-134a at a specified temperature is to be calculated using the Clapeyron equation and Clapeyron-Clausius equation and to be compared to the tabulated data.

**Analysis** (a) From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T \nu_{fg} \left( \frac{dP}{dT} \right)_{\text{sat}} \\
 &\cong T(\nu_g - \nu_f)_{@ 50^\circ\text{F}} \left( \frac{\Delta P}{\Delta T} \right)_{\text{sat}, 50^\circ\text{F}} \\
 &= T(\nu_g - \nu_f)_{@ 50^\circ\text{F}} \left( \frac{P_{\text{sat}@ 60^\circ\text{F}} - P_{\text{sat}@ 40^\circ\text{F}}}{60^\circ\text{F} - 40^\circ\text{F}} \right) \\
 &= (50 + 459.67 \text{ R})(0.79136 - 0.01270 \text{ ft}^3/\text{lbm}) \left( \frac{(72.152 - 49.776) \text{ psia}}{20 \text{ R}} \right) \\
 &= 444.0 \text{ psia} \cdot \text{ft}^3/\text{lbm} = \mathbf{82.16 \text{ Btu/lbm}} \quad (0.2\% \text{ error})
 \end{aligned}$$

since  $1 \text{ Btu} = 5.4039 \text{ psia} \cdot \text{ft}^3$ .

(b) From the Clapeyron-Clausius equation,

$$\begin{aligned}
 \ln \left( \frac{P_2}{P_1} \right)_{\text{sat}} &\cong \frac{h_{fg}}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)_{\text{sat}} \\
 \ln \left( \frac{72.152 \text{ psia}}{49.776 \text{ psia}} \right) &\cong \frac{h_{fg}}{0.01946 \text{ Btu/lbm} \cdot \text{R}} \left( \frac{1}{40 + 459.67 \text{ R}} - \frac{1}{60 + 459.67 \text{ R}} \right) \\
 h_{fg} &= \mathbf{93.80 \text{ Btu/lbm}} \quad (14.4\% \text{ error})
 \end{aligned}$$

The tabulated value of  $h_{fg}$  at  $50^\circ\text{F}$  is **82.00 Btu/lbm**.

**12-27 EES** The enthalpy of vaporization of steam as a function of temperature using Clapeyron equation and steam data in EES is to be plotted.

**Analysis** The enthalpy of vaporization is determined using Clapeyron equation from

$$h_{fg, \text{Clapeyron}} = T \nu_{fg} \frac{\Delta P}{\Delta T}$$

At 100°C, for an increment of 5°C, we obtain

$$\begin{aligned} T_1 &= T - T_{\text{increment}} = 100 - 5 = 95^\circ\text{C} \\ T_2 &= T + T_{\text{increment}} = 100 + 5 = 105^\circ\text{C} \\ P_1 &= P_{\text{sat}@ } 95^\circ\text{C}} = 84.61 \text{ kPa} \\ P_2 &= P_{\text{sat}@ } 105^\circ\text{C}} = 120.90 \text{ kPa} \\ \Delta T &= T_2 - T_1 = 105 - 95 = 10^\circ\text{C} \\ \Delta P &= P_2 - P_1 = 120.90 - 84.61 = 36.29 \text{ kPa} \\ \nu_{f@ 100^\circ\text{C}} &= 0.001043 \text{ m}^3/\text{kg} \\ \nu_{g@ 100^\circ\text{C}} &= 1.6720 \text{ m}^3/\text{kg} \\ \nu_{fg} &= \nu_g - \nu_f = 1.6720 - 0.001043 = 1.6710 \text{ m}^3/\text{kg} \end{aligned}$$

Substituting,

$$h_{fg, \text{Clapeyron}} = T \nu_{fg} \frac{\Delta P}{\Delta T} = (100 + 273.15 \text{ K})(1.6710 \text{ m}^3/\text{kg}) \frac{36.29 \text{ kPa}}{10 \text{ K}} = \mathbf{2262.8 \text{ kJ/kg}}$$

The enthalpy of vaporization from steam table is

$$h_{fg@ 100^\circ\text{C}} = \mathbf{2256.4 \text{ kJ/kg}}$$

The percent error in using Clapeyron equation is

$$\text{PercentError} = \frac{2262.8 - 2256.4}{2256.4} \times 100 = \mathbf{0.28\%}$$

We repeat the analysis over the temperature range 10 to 200°C using EES. Below, the copy of EES solution is provided:

```
"Input Data:"
"T=100" "[C]"
T_increment = 5 "[C]"
T[2]=T+T_increment "[C]"
T[1]=T-T_increment "[C]"
P[1] = pressure(Steam_iapws,T=T[1],x=0) "[kPa]"
P[2] = pressure(Steam_iapws,T=T[2],x=0) "[kPa]"

"The Clapeyron equation (Eq. 11-22) provides a means to calculate the enthalpy of vaporization,  $h_{fg}$  at a given temperature by determining the slope of the saturation curve on a P-T diagram and the specific volume of the saturated liquid and saturated vapor at the temperature."

$h_{fg\_Clapeyron} = (T + 273.15) * v_{fg} * \Delta P / \Delta T * \text{Convert}(m^3\text{-kPa}, kJ) [kJ/kg]$   
 $\text{PercentError} = \text{ABS}(h_{fg\_Clapeyron} - h_{fg}) / h_{fg} * 100 [\%]$

**12-28** A substance is heated in a piston-cylinder device until it turns from saturated liquid to saturated vapor at a constant pressure and temperature. The boiling temperature of this substance at a different pressure is to be estimated.

**Analysis** From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T v_{fg}} = \frac{(5 \text{ kPa} \cdot \text{m}^3)/(0.002 \text{ kg})}{(353 \text{ K})(1 \times 10^{-3} \text{ m}^3)/(0.002 \text{ kg})} = 14.16 \text{ kPa/K}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for  $T_2$ ,

$$T_2 = T_1 + \frac{P_2 - P_1}{dP/dT} = 353 \text{ K} + \frac{(180 - 200) \text{ kPa}}{14.16 \text{ kPa/K}} = \mathbf{351.6 \text{ K}}$$

**12-29** A substance is heated in a piston-cylinder device until it turns from saturated liquid to saturated vapor at a constant pressure and temperature. The saturation pressure of this substance at a different temperature is to be estimated.

**Analysis** From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T v_{fg}} = \frac{(5 \text{ kPa} \cdot \text{m}^3)/(0.002 \text{ kg})}{(353 \text{ K})(1 \times 10^{-3} \text{ m}^3)/(0.002 \text{ kg})} = 14.16 \text{ kPa/K}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for  $P_2$ ,

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 200 \text{ kPa} + (14.16 \text{ kPa/K})(373 - 353) \text{ K} = \mathbf{483.2 \text{ kPa}}$$

**12-30** A substance is heated in a piston-cylinder device until it turns from saturated liquid to saturated vapor at a constant pressure and temperature. The  $s_{fg}$  of this substance at a different temperature is to be estimated.

**Analysis** From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{s_{fg}}{\nu_{fg}}$$

Solving for  $s_{fg}$ ,

$$s_{fg} = \frac{h_{fg}}{T} = \frac{(5 \text{ kJ})/(0.002 \text{ kg})}{353 \text{ K}} = \mathbf{7.082 \text{ kJ/kg} \cdot \text{K}}$$

Alternatively,

$$s_{fg} = \left(\frac{dP}{dT}\right)_{\text{sat}} \nu_{fg} = (14.16 \text{ kPa/K}) \frac{1 \times 10^{-3} \text{ m}^3}{0.002 \text{ kg}} = 7.08 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K} = 7.08 \text{ kJ/kg} \cdot \text{K}$$

**12-31** It is to be shown that  $c_{p,g} - c_{p,f} = T \left( \frac{\partial(h_{fg}/T)}{\partial T} \right)_P + \nu_{fg} \left( \frac{\partial P}{\partial T} \right)_{\text{sat}}$ .

**Analysis** The definition of specific heat and Clapeyron equation are

$$c_p = \left( \frac{\partial h}{\partial T} \right)_P$$

$$\left( \frac{dP}{dT} \right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

According to the definition of the enthalpy of vaporization,

$$\frac{h_{fg}}{T} = \frac{h_g}{T} - \frac{h_f}{T}$$

Differentiating this expression gives

$$\begin{aligned} \left( \frac{\partial(h_{fg}/T)}{\partial T} \right)_P &= \left( \frac{\partial h_g/T}{\partial T} \right)_P - \left( \frac{\partial h_f/T}{\partial T} \right)_P \\ &= \frac{1}{T} \left( \frac{\partial h_g}{\partial T} \right)_P - \frac{h_g}{T^2} - \frac{1}{T} \left( \frac{\partial h_f}{\partial T} \right)_P + \frac{h_f}{T^2} \\ &= \frac{c_{p,g}}{T} - \frac{c_{p,f}}{T} - \frac{h_g - h_f}{T^2} \end{aligned}$$

Using Clapeyron to replace the last term of this expression and solving for the specific heat difference gives

$$c_{p,g} - c_{p,f} = T \left( \frac{\partial(h_{fg}/T)}{\partial T} \right)_P + \nu_{fg} \left( \frac{\partial P}{\partial T} \right)_{\text{sat}}$$

**12-32E** A table of properties for methyl chloride is given. The saturation pressure is to be estimated at two different temperatures.

**Analysis** The Clapeyron equation is

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

Solving this for the second pressure gives for  $T_2 = 110^\circ\text{F}$

$$\begin{aligned} P_2 &= P_1 + \frac{h_{fg}}{T\nu_{fg}}(T_2 - T_1) \\ &= 116.7 \text{ psia} + \frac{154.85 \text{ Btu/lbm}}{(560 \text{ R})(0.86332 \text{ ft}^3/\text{lbm})} \left( \frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) (110 - 100) \text{ R} \\ &= \mathbf{134.0 \text{ psia}} \end{aligned}$$

When  $T_2 = 90^\circ\text{F}$

$$\begin{aligned} P_2 &= P_1 + \frac{h_{fg}}{T\nu_{fg}}(T_2 - T_1) \\ &= 116.7 \text{ psia} + \frac{154.85 \text{ Btu/lbm}}{(560 \text{ R})(0.86332 \text{ ft}^3/\text{lbm})} \left( \frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) (90 - 100) \text{ R} \\ &= \mathbf{99.4 \text{ psia}} \end{aligned}$$

**12-33** Saturation properties for R-134a at a specified temperature are given. The saturation pressure is to be estimated at two different temperatures.

**Analysis** From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T v_{fg}} = \frac{225.86 \text{ kPa} \cdot \text{m}^3/\text{kg}}{(233 \text{ K})(0.36010 \text{ m}^3/\text{kg})} = 2.692 \text{ kPa/K}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for  $P_2$  at  $-50^\circ\text{C}$

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 51.25 \text{ kPa} + (2.692 \text{ kPa/K})(223 - 233)\text{K} = \mathbf{24.33 \text{ kPa}}$$

Solving for  $P_2$  at  $-30^\circ\text{C}$

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 51.25 \text{ kPa} + (2.692 \text{ kPa/K})(243 - 233)\text{K} = \mathbf{78.17 \text{ kPa}}$$

**General Relations for du, dh, ds, c<sub>v</sub>, and c<sub>p</sub>**

**12-34C** Yes, through the relation

$$\left(\frac{\partial c_p}{\partial P}\right)_T = -T \left(\frac{\partial^2 \nu}{\partial T^2}\right)_P$$

**12-35** General expressions for  $\Delta u$ ,  $\Delta h$ , and  $\Delta s$  for a gas whose equation of state is  $P(\nu - a) = RT$  for an isothermal process are to be derived.

**Analysis** (a) A relation for  $\Delta u$  is obtained from the general relation

$$\Delta u = u_2 - u_1 = \int_{T_1}^{T_2} c_\nu dT + \int_{\nu_1}^{\nu_2} \left( T \left( \frac{\partial P}{\partial T} \right)_\nu - P \right) d\nu$$

The equation of state for the specified gas can be expressed as

$$P = \frac{RT}{\nu - a} \longrightarrow \left( \frac{\partial P}{\partial T} \right)_\nu = \frac{R}{\nu - a}$$

Thus,

$$T \left( \frac{\partial P}{\partial T} \right)_\nu - P = \frac{RT}{\nu - a} - P = P - P = 0$$

Substituting,  $\Delta u = \int_{T_1}^{T_2} c_\nu dT$

(b) A relation for  $\Delta h$  is obtained from the general relation

$$\Delta h = h_2 - h_1 = \int_{T_1}^{T_2} c_p dT + \int_{P_1}^{P_2} \left( \nu - T \left( \frac{\partial \nu}{\partial T} \right)_P \right) dP$$

The equation of state for the specified gas can be expressed as

$$\nu = \frac{RT}{P} + a \longrightarrow \left( \frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

Thus,

$$\nu - T \left( \frac{\partial \nu}{\partial T} \right)_P = \nu - T \frac{R}{P} = \nu - (\nu - a) = a$$

Substituting,

$$\Delta h = \int_{T_1}^{T_2} c_p dT + \int_{P_1}^{P_2} a dP = \int_{T_1}^{T_2} c_p dT + a(P_2 - P_1)$$

(c) A relation for  $\Delta s$  is obtained from the general relation

$$\Delta s = s_2 - s_1 = \int_{T_1}^{T_2} \frac{c_p}{T} dT - \int_{P_1}^{P_2} \left( \frac{\partial \nu}{\partial T} \right)_P dP$$

Substituting  $(\partial \nu / \partial T)_P = R/T$ ,

$$\Delta s = \int_{T_1}^{T_2} \frac{c_p}{T} dT - \int_{P_1}^{P_2} \left( \frac{R}{P} \right)_P dP = \int_{T_1}^{T_2} \frac{c_p}{T} dT - R \ln \frac{P_2}{P_1}$$

For an isothermal process  $dT = 0$  and these relations reduce to

$$\Delta u = 0, \quad \Delta h = a(P_2 - P_1), \quad \text{and} \quad \Delta s = -R \ln \frac{P_2}{P_1}$$

**12-36** General expressions for  $(\partial u/\partial P)_T$  and  $(\partial h/\partial \nu)_T$  in terms of  $P$ ,  $\nu$ , and  $T$  only are to be derived.

**Analysis** The general relation for  $du$  is

$$du = c_\nu dT + \left( T \left( \frac{\partial P}{\partial T} \right)_\nu - P \right) d\nu$$

Differentiating each term in this equation with respect to  $P$  at  $T = \text{constant}$  yields

$$\left( \frac{\partial u}{\partial P} \right)_T = 0 + \left( T \left( \frac{\partial P}{\partial T} \right)_\nu - P \right) \left( \frac{\partial \nu}{\partial P} \right)_T = T \left( \frac{\partial P}{\partial T} \right)_\nu \left( \frac{\partial \nu}{\partial P} \right)_T - P \left( \frac{\partial \nu}{\partial P} \right)_T$$

Using the properties  $P$ ,  $T$ ,  $\nu$ , the cyclic relation can be expressed as

$$\left( \frac{\partial P}{\partial T} \right)_\nu \left( \frac{\partial T}{\partial \nu} \right)_P \left( \frac{\partial \nu}{\partial P} \right)_T = -1 \longrightarrow \left( \frac{\partial P}{\partial T} \right)_\nu \left( \frac{\partial \nu}{\partial P} \right)_T = - \left( \frac{\partial \nu}{\partial T} \right)_P$$

Substituting, we get

$$\left( \frac{\partial u}{\partial P} \right)_T = -T \left( \frac{\partial \nu}{\partial T} \right)_P - P \left( \frac{\partial \nu}{\partial P} \right)_T$$

The general relation for  $dh$  is

$$dh = c_p dT + \left( \nu - T \left( \frac{\partial \nu}{\partial T} \right)_P \right) dP$$

Differentiating each term in this equation with respect to  $\nu$  at  $T = \text{constant}$  yields

$$\left( \frac{\partial h}{\partial \nu} \right)_T = 0 + \left( \nu - T \left( \frac{\partial \nu}{\partial T} \right)_P \right) \left( \frac{\partial P}{\partial \nu} \right)_T = \nu \left( \frac{\partial P}{\partial \nu} \right)_T - T \left( \frac{\partial \nu}{\partial T} \right)_P \left( \frac{\partial P}{\partial \nu} \right)_T$$

Using the properties  $\nu$ ,  $T$ ,  $P$ , the cyclic relation can be expressed as

$$\left( \frac{\partial \nu}{\partial T} \right)_P \left( \frac{\partial T}{\partial P} \right)_\nu \left( \frac{\partial P}{\partial \nu} \right)_T = -1 \longrightarrow \left( \frac{\partial \nu}{\partial T} \right)_P \left( \frac{\partial P}{\partial \nu} \right)_T = - \left( \frac{\partial T}{\partial P} \right)_\nu$$

Substituting, we get

$$\left( \frac{\partial h}{\partial \nu} \right)_T = \nu \left( \frac{\partial P}{\partial \nu} \right)_T + T \left( \frac{\partial T}{\partial P} \right)_\nu$$

**12-37E** The specific heat difference  $c_p - c_v$  for liquid water at 1000 psia and 150°F is to be estimated.

**Analysis** The specific heat difference  $c_p - c_v$  is given as

$$c_p - c_v = -T \left( \frac{\partial v}{\partial T} \right)_P \left( \frac{\partial P}{\partial v} \right)_T$$

Approximating differentials by differences about the specified state,

$$\begin{aligned} c_p - c_v &\cong -T \left( \frac{\Delta v}{\Delta T} \right)_{P=1000 \text{ psia}} \left( \frac{\Delta P}{\Delta v} \right)_{T=150^\circ \text{F}} \\ &= -(150 + 459.67 \text{ R}) \left( \frac{v_{175^\circ \text{F}} - v_{125^\circ \text{F}}}{(175 - 125)^\circ \text{F}} \right)_{P=1000 \text{ psia}} \left( \frac{(1500 - 500) \text{ psia}}{v_{1500 \text{ psia}} - v_{500 \text{ psia}}} \right)_{T=150^\circ \text{F}} \\ &= -(609.67 \text{ R}) \left( \frac{(0.016427 - 0.016177) \text{ ft}^3/\text{lbm}}{50 \text{ R}} \right)^2 \left( \frac{1000 \text{ psia}}{(0.016267 - 0.016317) \text{ ft}^3/\text{lbm}} \right) \\ &= 0.3081 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R} \\ &= \mathbf{0.0570 \text{ Btu/lbm} \cdot \text{R}} \quad (1 \text{ Btu} = 5.4039 \text{ psia} \cdot \text{ft}^3) \end{aligned}$$

**12-38** The volume expansivity  $\beta$  and the isothermal compressibility  $\alpha$  of refrigerant-134a at 200 kPa and 30°C are to be estimated.

**Analysis** The volume expansivity and isothermal compressibility are expressed as

$$\beta = \frac{1}{v} \left( \frac{\partial v}{\partial T} \right)_P \quad \text{and} \quad \alpha = -\frac{1}{v} \left( \frac{\partial v}{\partial P} \right)_T$$

Approximating differentials by differences about the specified state,

$$\begin{aligned} \beta &\cong \frac{1}{v} \left( \frac{\Delta v}{\Delta T} \right)_{P=200 \text{ kPa}} = \frac{1}{v} \left( \frac{v_{40^\circ \text{C}} - v_{20^\circ \text{C}}}{(40 - 20)^\circ \text{C}} \right)_{P=200 \text{ kPa}} \\ &= \frac{1}{0.11874 \text{ m}^3/\text{kg}} \left( \frac{(0.12322 - 0.11418) \text{ m}^3/\text{kg}}{20 \text{ K}} \right) \\ &= \mathbf{0.00381 \text{ K}^{-1}} \end{aligned}$$

and

$$\begin{aligned} \alpha &\cong -\frac{1}{v} \left( \frac{\Delta v}{\Delta P} \right)_{T=30^\circ \text{C}} = -\frac{1}{v} \left( \frac{v_{240 \text{ kPa}} - v_{180 \text{ kPa}}}{(240 - 180) \text{ kPa}} \right)_{T=30^\circ \text{C}} \\ &= -\frac{1}{0.11874 \text{ m}^3/\text{kg}} \left( \frac{(0.09812 - 0.13248) \text{ m}^3/\text{kg}}{60 \text{ kPa}} \right) \\ &= \mathbf{0.00482 \text{ kPa}^{-1}} \end{aligned}$$

**12-39** It is to be shown that  $c_p - c_v = T \left( \frac{\partial P}{\partial T} \right)_v \left( \frac{\partial v}{\partial T} \right)_p$ .

**Analysis** We begin by taking the entropy to be a function of specific volume and temperature. The differential of the entropy is then

$$ds = \left( \frac{\partial s}{\partial T} \right)_v dT + \left( \frac{\partial s}{\partial v} \right)_T dv$$

Substituting  $\left( \frac{\partial s}{\partial T} \right)_v = \frac{c_v}{T}$  from Eq. 12-28 and the third Maxwell equation changes this to

$$ds = \frac{c_v}{T} dT + \left( \frac{\partial P}{\partial T} \right)_v dv$$

Taking the entropy to be a function of pressure and temperature,

$$ds = \left( \frac{\partial s}{\partial T} \right)_p dT + \left( \frac{\partial s}{\partial P} \right)_T dP$$

Combining this result with  $\left( \frac{\partial s}{\partial T} \right)_p = \frac{c_p}{T}$  from Eq. 12-34 and the fourth Maxwell equation produces

$$ds = \frac{c_p}{T} dT - \left( \frac{\partial v}{\partial T} \right)_p dP$$

Equating the two previous  $ds$  expressions and solving the result for the specific heat difference,

$$(c_p - c_v)dT = T \left( \frac{\partial v}{\partial T} \right)_p dP + \left( \frac{\partial P}{\partial T} \right)_v dv$$

Taking the pressure to be a function of temperature and volume,

$$dP = \left( \frac{\partial P}{\partial T} \right)_v dT + \left( \frac{\partial P}{\partial v} \right)_T dv$$

When this is substituted into the previous expression, the result is

$$(c_p - c_v)dT = T \left( \frac{\partial v}{\partial T} \right)_p \left( \frac{\partial P}{\partial T} \right)_v dT + T \left[ \left( \frac{\partial v}{\partial T} \right)_p \left( \frac{\partial P}{\partial v} \right)_T \left( \frac{\partial P}{\partial T} \right)_v \right] dv$$

According to the cyclic relation, the term in the bracket is zero. Then, canceling the common  $dT$  term,

$$c_p - c_v = T \left( \frac{\partial P}{\partial T} \right)_v \left( \frac{\partial v}{\partial T} \right)_p$$

**12-40** It is to be proven that the definition for temperature  $T = (\partial u / \partial s)_v$  reduces the net entropy change of two constant-volume systems filled with simple compressible substances to zero as the two systems approach thermal equilibrium.

**Analysis** The two constant-volume systems form an isolated system shown here

For the isolated system

$$dS_{\text{tot}} = dS_A + dS_B \geq 0$$

Assume  $S = S(u, v)$

Then,

$$ds = \left( \frac{\partial s}{\partial u} \right)_v du + \left( \frac{\partial s}{\partial v} \right)_u dv$$

Since  $v = \text{const.}$  and  $dv = 0$ ,

$$ds = \left( \frac{\partial s}{\partial u} \right)_v du$$

and from the definition of temperature from the problem statement,

$$\frac{du}{(\partial u / \partial s)_v} = \frac{du}{T}$$

Then,

$$dS_{\text{tot}} = m_A \frac{du_A}{T_A} + m_B \frac{du_B}{T_B}$$

The first law applied to the isolated system yields

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= dU \\ 0 &= dU \longrightarrow m_A du_A + m_B du_B = 0 \longrightarrow m_B du_B = -m_A du_A \end{aligned}$$

Now, the entropy change may be expressed as

$$dS_{\text{tot}} = m_A du_A \left( \frac{1}{T_A} - \frac{1}{T_B} \right) = m_A du_A \left( \frac{T_B - T_A}{T_A T_B} \right)$$

As the two systems approach thermal equilibrium,

$$\begin{aligned} \lim dS_{\text{tot}} &= 0 \\ T_A &\rightarrow T_B \end{aligned}$$

**12-41** The internal energy change of air between two specified states is to be compared for two equations of states.

**Assumptions** Constant specific heats for air can be used.

**Properties** For air at the average temperature  $(20+300)/2=160^\circ\text{C}=433\text{ K}$ ,  $c_v = 0.731\text{ kJ/kg}\cdot\text{K}$  (Table A-2b).

**Analysis** Solving the equation of state for  $P$  gives

$$P = \frac{RT}{v - a}$$

Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v - a}$$

Using equation 12-29,

$$du = c_v dT + \left[ T \left(\frac{\partial P}{\partial T}\right)_v - P \right] dv$$

Substituting,

$$\begin{aligned} du &= c_v dT + \left( \frac{RT}{v - a} - \frac{RT}{v - a} \right) dv \\ &= c_v dT \end{aligned}$$

Integrating this result between the two states with constant specific heats gives

$$u_2 - u_1 = c_v (T_2 - T_1) = (0.731\text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{205\text{ kJ/kg}}$$

The ideal gas model for the air gives

$$du = c_v dT$$

which gives the same answer.

**12-42** The enthalpy change of air between two specified states is to be compared for two equations of states.

**Assumptions** Constant specific heats for air can be used.

**Properties** For air at the average temperature  $(20+300)/2=160^\circ\text{C}=433\text{ K}$ ,  $c_p = 1.018\text{ kJ/kg}\cdot\text{K}$  (Table A-2b).

**Analysis** Solving the equation of state for  $\nu$  gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

Using equation 12-35,

$$dh = c_p dT + \left[ \nu - T \left( \frac{\partial \nu}{\partial T} \right)_P \right] dP$$

Substituting,

$$\begin{aligned} dh &= c_p dT + \left( \frac{RT}{P} + a - \frac{RT}{P} \right) dP \\ &= c_p dT + a dP \end{aligned}$$

Integrating this result between the two states with constant specific heats gives

$$\begin{aligned} h_2 - h_1 &= c_p (T_2 - T_1) + a(P_2 - P_1) \\ &= (1.018\text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} + (0.10\text{ m}^3/\text{kg})(600 - 100)\text{kPa} \\ &= \mathbf{335.0\text{ kJ/kg}} \end{aligned}$$

For an ideal gas,

$$dh = c_p dT$$

which when integrated gives

$$h_2 - h_1 = c_p (T_2 - T_1) = (1.018\text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{285.0\text{ kJ/kg}}$$

**12-43** The entropy change of air between two specified states is to be compared for two equations of states.

**Assumptions** Constant specific heats for air can be used.

**Properties** For air at the average temperature  $(20+300)/2=160^\circ\text{C}=433\text{ K}$ ,  $c_p = 1.018\text{ kJ/kg}\cdot\text{K}$  (Table A-2b) and  $R = 0.287\text{ kJ/kg}\cdot\text{K}$  (Table A-1).

**Analysis** Solving the equation of state for  $\nu$  gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The entropy differential is

$$\begin{aligned} ds &= c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP \\ &= c_p \frac{dT}{T} - R \frac{dP}{P} \end{aligned}$$

which is the same as that of an ideal gas. Integrating this result between the two states with constant specific heats gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.018\text{ kJ/kg}\cdot\text{K}) \ln \frac{573\text{ K}}{293\text{ K}} - (0.287\text{ kJ/kg}\cdot\text{K}) \ln \frac{600\text{ kPa}}{100\text{ kPa}} \\ &= \mathbf{0.1686\text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

**12-44** The internal energy change of helium between two specified states is to be compared for two equations of states.

**Properties** For helium,  $c_v = 3.1156 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** Solving the equation of state for  $P$  gives

$$P = \frac{RT}{v - a}$$

Then,

$$\left( \frac{\partial P}{\partial T} \right)_v = \frac{R}{v - a}$$

Using equation 12-29,

$$du = c_v dT + \left[ T \left( \frac{\partial P}{\partial T} \right)_v - P \right] dv$$

Substituting,

$$\begin{aligned} du &= c_v dT + \left( \frac{RT}{v - a} - \frac{RT}{v - a} \right) dv \\ &= c_v dT \end{aligned}$$

Integrating this result between the two states gives

$$u_2 - u_1 = c_v (T_2 - T_1) = (3.1156 \text{ kJ/kg} \cdot \text{K})(300 - 20) \text{ K} = \mathbf{872.4 \text{ kJ/kg}}$$

The ideal gas model for the helium gives

$$du = c_v dT$$

which gives the same answer.

**12-45** The enthalpy change of helium between two specified states is to be compared for two equations of states.

**Properties** For helium,  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Solving the equation of state for  $\nu$  gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

Using equation 12-35,

$$dh = c_p dT + \left[ \nu - T \left( \frac{\partial \nu}{\partial T} \right)_P \right] dP$$

Substituting,

$$\begin{aligned} dh &= c_p dT + \left( \frac{RT}{P} + a - \frac{RT}{P} \right) dP \\ &= c_p dT + a dP \end{aligned}$$

Integrating this result between the two states gives

$$\begin{aligned} h_2 - h_1 &= c_p (T_2 - T_1) + a(P_2 - P_1) \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} + (0.10 \text{ m}^3/\text{kg})(600 - 100)\text{kPa} \\ &= \mathbf{1504 \text{ kJ/kg}} \end{aligned}$$

For an ideal gas,

$$dh = c_p dT$$

which when integrated gives

$$h_2 - h_1 = c_p (T_2 - T_1) = (5.1926 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{1454 \text{ kJ/kg}}$$

**12-46** The entropy change of helium between two specified states is to be compared for two equations of states.

**Properties** For helium,  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  and  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Solving the equation of state for  $\nu$  gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The entropy differential is

$$\begin{aligned} ds &= c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP \\ &= c_p \frac{dT}{T} - R \frac{dP}{P} \end{aligned}$$

which is the same as that of an ideal gas. Integrating this result between the two states gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K}) \ln \frac{573 \text{ K}}{293 \text{ K}} - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln \frac{600 \text{ kPa}}{100 \text{ kPa}} \\ &= \mathbf{-0.2386 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

**12-47** An expression for the volume expansivity of a substance whose equation of state is  $P(\nu - a) = RT$  is to be derived.

**Analysis** Solving the equation of state for  $\nu$  gives

$$\nu = \frac{RT}{P} + a$$

The specific volume derivative is then

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The definition for volume expansivity is

$$\beta = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T}\right)_P$$

Combining these two equations gives

$$\beta = \frac{R}{RT + aP}$$

**12-48** The Helmholtz function of a substance has the form  $a = -RT \ln \frac{\nu}{\nu_0} - cT_0 \left( 1 - \frac{T}{T_0} + \frac{T}{T_0} \ln \frac{T}{T_0} \right)$ . It is to be shown how to obtain  $P$ ,  $h$ ,  $s$ ,  $c_\nu$  and  $c_p$  from this expression.

**Analysis** Taking the Helmholtz function to be a function of temperature and specific volume yields

$$da = \left( \frac{\partial a}{\partial T} \right)_\nu dT + \left( \frac{\partial a}{\partial \nu} \right)_T d\nu$$

while the applicable Helmholtz equation is

$$da = -Pd\nu - sdT$$

Equating the coefficients of the two results produces

$$P = - \left( \frac{\partial a}{\partial \nu} \right)_T$$

$$s = - \left( \frac{\partial a}{\partial T} \right)_\nu$$

Taking the indicated partial derivatives of the Helmholtz function given in the problem statement reduces these expressions to

$$P = \frac{RT}{\nu}$$

$$s = R \ln \frac{\nu}{\nu_0} + c \ln \frac{T}{T_0}$$

The definition of the enthalpy ( $h = u + P\nu$ ) and Helmholtz function ( $a = u - Ts$ ) may be combined to give

$$\begin{aligned} h &= u + P\nu \\ &= a + Ts + P\nu \\ &= a - T \left( \frac{\partial a}{\partial T} \right)_\nu - \nu \left( \frac{\partial a}{\partial \nu} \right)_T \\ &= -RT \ln \frac{\nu}{\nu_0} - cT_0 \left( 1 - \frac{T}{T_0} + \frac{T}{T_0} \ln \frac{T}{T_0} \right) + RT \ln \frac{\nu}{\nu_0} - cT \ln \frac{T}{T_0} + RT \\ &= cT_0 + cT + RT \end{aligned}$$

According to  $\left( \frac{\partial s}{\partial T} \right)_\nu = \frac{c_\nu}{T}$  given in the text (Eq. 12-28),

$$c_\nu = T \left( \frac{\partial s}{\partial T} \right)_\nu = T \frac{c}{T} = c$$

The preceding expression for the temperature indicates that the equation of state for the substance is the same as that of an ideal gas. Then,

$$c_p = R + c_\nu = R + c$$

**12-49** An expression for the volume expansivity of a substance whose equation of state

is  $P = \frac{RT}{\nu - b} - \frac{a}{\nu(\nu + b)T^{1/2}}$  is to be derived.

**Analysis** The definition for volume expansivity is

$$\beta = \frac{1}{\nu} \left( \frac{\partial \nu}{\partial T} \right)_P$$

According to the cyclic relation,

$$\left( \frac{\partial \nu}{\partial T} \right)_P \left( \frac{\partial P}{\partial \nu} \right)_T \left( \frac{\partial T}{\partial P} \right)_\nu = -1$$

which on rearrangement becomes

$$\left( \frac{\partial \nu}{\partial T} \right)_P = - \frac{\left( \frac{\partial P}{\partial T} \right)_\nu}{\left( \frac{\partial P}{\partial \nu} \right)_T}$$

Proceeding to perform the differentiations gives

$$\left( \frac{\partial P}{\partial T} \right)_\nu = \frac{R}{\nu - b} + \frac{a}{2\nu(\nu + b)T^{3/2}}$$

and

$$\begin{aligned} \left( \frac{\partial P}{\partial \nu} \right)_T &= -\frac{RT}{(\nu - b)^2} + \frac{a}{bT^{1/2}} \left[ \frac{1}{\nu^2} - \frac{1}{(\nu + b)^2} \right] \\ &= -\frac{RT}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{\nu^2(\nu + b)^2} \end{aligned}$$

Substituting these results into the definition of the volume expansivity produces

$$\beta = -\frac{1}{\nu} \frac{\frac{R}{\nu - b} + \frac{a}{2\nu(\nu + b)T^{3/2}}}{-\frac{RT}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{\nu^2(\nu + b)^2}}$$

**12-50** An expression for the specific heat difference of a substance whose equation of state

is  $P = \frac{RT}{v-b} - \frac{a}{v(v+b)T^{1/2}}$  is to be derived.

**Analysis** The specific heat difference is expressed by

$$c_p - c_v = -T \left( \frac{\partial v}{\partial T} \right)_p^2 \left( \frac{\partial P}{\partial v} \right)_T$$

According to the cyclic relation,

$$\left( \frac{\partial v}{\partial T} \right)_p \left( \frac{\partial P}{\partial v} \right)_T \left( \frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left( \frac{\partial v}{\partial T} \right)_p = - \left( \frac{\partial P}{\partial T} \right)_v \left( \frac{\partial P}{\partial v} \right)_T^{-1}$$

Substituting this result into the expression for the specific heat difference gives

$$c_p - c_v = -T \left( \frac{\partial P}{\partial T} \right)_v^2 \left( \frac{\partial P}{\partial v} \right)_T^{-1}$$

The appropriate partial derivatives of the equation of state are

$$\begin{aligned} \left( \frac{\partial P}{\partial T} \right)_v &= \frac{R}{v-b} + \frac{a/2}{v(v+b)T^{3/2}} \\ \left( \frac{\partial P}{\partial v} \right)_T &= -\frac{RT}{(v-b)^2} + \frac{a}{bT^{1/2}} \left[ \frac{1}{v^2} - \frac{1}{(v+b)^2} \right] \\ &= -\frac{RT}{(v-b)^2} + \frac{a}{T^{1/2}} \frac{2v+b}{v^2(v+b)^2} \end{aligned}$$

The difference in the specific heats is then

$$c_p - c_v = \frac{-T \left[ \frac{R}{v-b} + \frac{a/2}{v(v+b)T^{3/2}} \right]^2}{-\frac{RT}{(v-b)^2} + \frac{a}{T^{1/2}} \frac{2v+b}{v^2(v+b)^2}}$$

**12-51** An expression for the volume expansivity of a substance whose equation of state is  $P = \frac{RT}{v-b} - \frac{a}{v^2T}$  is to be derived.

**Analysis** The definition for volume expansivity is

$$\beta = \frac{1}{v} \left( \frac{\partial v}{\partial T} \right)_P$$

According to the cyclic relation,

$$\left( \frac{\partial v}{\partial T} \right)_P \left( \frac{\partial P}{\partial v} \right)_T \left( \frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left( \frac{\partial v}{\partial T} \right)_P = - \frac{\left( \frac{\partial P}{\partial T} \right)_v}{\left( \frac{\partial P}{\partial v} \right)_T}$$

Proceeding to perform the differentiations gives

$$\left( \frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b} + \frac{a}{v^2 T^2}$$

and

$$\left( \frac{\partial P}{\partial v} \right)_T = - \frac{RT}{(v-b)^2} + \frac{2a}{v^3 T}$$

Substituting these results into the definition of the volume expansivity produces

$$\beta = - \frac{1}{v} \frac{\frac{R}{v-b} + \frac{a}{v^2 T^2}}{\frac{-RT}{(v-b)^2} + \frac{2a}{v^3 T}}$$

**12-52** An expression for the isothermal compressibility of a substance whose equation of state is  $P = \frac{RT}{v-b} - \frac{a}{v^2T}$  is to be derived.

**Analysis** The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{v} \left( \frac{\partial v}{\partial P} \right)_T$$

Now,

$$\left( \frac{\partial P}{\partial v} \right)_T = \frac{-RT}{(v-b)^2} + \frac{2a}{v^3T}$$

Using the partial derivative properties,

$$\alpha = -\frac{1}{v \left( \frac{\partial P}{\partial v} \right)_T} = -\frac{1}{\frac{-RTv}{(v-b)^2} + \frac{2a}{v^2T}}$$

**12-53** It is to be shown that  $\beta = \alpha \left( \frac{\partial P}{\partial T} \right)_v$ .

**Analysis** The definition for the volume expansivity is

$$\beta = \frac{1}{v} \left( \frac{\partial v}{\partial T} \right)_P$$

The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{v} \left( \frac{\partial v}{\partial P} \right)_T$$

According to the cyclic relation,

$$\left( \frac{\partial v}{\partial T} \right)_P \left( \frac{\partial P}{\partial v} \right)_T \left( \frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left( \frac{\partial v}{\partial T} \right)_P = - \left( \frac{\partial v}{\partial P} \right)_T \left( \frac{\partial P}{\partial T} \right)_v$$

When this is substituted into the definition of the volume expansivity, the result is

$$\begin{aligned} \beta &= -\frac{1}{v} \left( \frac{\partial v}{\partial P} \right)_T \left( \frac{\partial P}{\partial T} \right)_v \\ &= -\alpha \left( \frac{\partial P}{\partial T} \right)_v \end{aligned}$$

**12-54** It is to be demonstrated that  $k = \frac{c_p}{c_v} = -\frac{\nu\alpha}{(\partial\nu/\partial P)_s}$ .

**Analysis** The relations for entropy differential are

$$ds = c_v \frac{dT}{T} + \left(\frac{\partial P}{\partial T}\right)_v d\nu$$

$$ds = c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP$$

For fixed  $s$ , these basic equations reduce to

$$c_v \frac{dT}{T} = -\left(\frac{\partial P}{\partial T}\right)_v d\nu$$

$$c_p \frac{dT}{T} = \left(\frac{\partial \nu}{\partial T}\right)_P dP$$

Also, when  $s$  is fixed,

$$\frac{\partial \nu}{\partial P} = \left(\frac{\partial \nu}{\partial P}\right)_s$$

Forming the specific heat ratio from these expressions gives

$$k = -\frac{\left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_v}{\left(\frac{\partial \nu}{\partial P}\right)_s}$$

The cyclic relation is

$$\left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial P}\right)_v = -1$$

Solving this for the numerator of the specific heat ratio expression and substituting the result into this numerator produces

$$k = \frac{\left(\frac{\partial \nu}{\partial P}\right)_T}{\left(\frac{\partial \nu}{\partial P}\right)_s} = -\frac{\nu\alpha}{\left(\frac{\partial \nu}{\partial P}\right)_s}$$

**12-55** An expression for the specific heat difference of a substance whose equation of state is  $P = \frac{RT}{v-b} - \frac{a}{v^2T}$  is to be derived.

**Analysis** The specific heat difference is expressed by

$$c_p - c_v = -T \left( \frac{\partial v}{\partial T} \right)_P^2 \left( \frac{\partial P}{\partial v} \right)_T$$

According to the cyclic relation,

$$\left( \frac{\partial v}{\partial T} \right)_P \left( \frac{\partial P}{\partial v} \right)_T \left( \frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left( \frac{\partial v}{\partial T} \right)_P = - \left( \frac{\partial P}{\partial T} \right)_v \left( \frac{\partial P}{\partial v} \right)_T^{-1}$$

Substituting this result into the expression for the specific heat difference gives

$$c_p - c_v = -T \left( \frac{\partial P}{\partial T} \right)_v^2 \left( \frac{\partial P}{\partial v} \right)_T^{-1}$$

The appropriate partial derivatives of the equation of state are

$$\left( \frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b} + \frac{a}{v^2 T^2}$$

$$\left( \frac{\partial P}{\partial v} \right)_T = - \frac{RT}{(v-b)^2} + \frac{2a}{v^3 T}$$

The difference in the specific heats is then

$$c_p - c_v = -T \frac{\left[ \frac{R}{v-b} + \frac{a}{v^2 T^2} \right]^2}{- \frac{RT}{(v-b)^2} + \frac{2a}{v^3 T}}$$

## The Joule-Thomson Coefficient

**12-56C** It represents the variation of temperature with pressure during a throttling process.

**12-57C** The line that passes through the peak points of the constant enthalpy lines on a  $T$ - $P$  diagram is called the inversion line. The maximum inversion temperature is the highest temperature a fluid can be cooled by throttling.

**12-58C** No. The temperature may even increase as a result of throttling.

**12-59C** Yes.

**12-60C** No. Helium is an ideal gas and  $h = h(T)$  for ideal gases. Therefore, the temperature of an ideal gas remains constant during a throttling ( $h = \text{constant}$ ) process.

**12-61E** [Also solved by EES on enclosed CD] The Joule-Thomson coefficient of nitrogen at two states is to be estimated.

**Analysis** (a) The enthalpy of nitrogen at 200 psia and 500 R is, from EES,  $h = -10.564$  Btu/lbm. Note that in EES, by default, the reference state for specific enthalpy and entropy is 0 at 25°C (77°F) and 1 atm. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left( \frac{\partial T}{\partial P} \right)_h \cong \left( \frac{\Delta T}{\Delta P} \right)_{h=-10.564 \text{ Btu/lbm}}$$

Considering a throttling process from 210 psia to 190 psia at  $h = -10.564$  Btu/lbm, the Joule-Thomson coefficient is determined to be

$$\mu = \left( \frac{T_{190 \text{ psia}} - T_{210 \text{ psia}}}{(190 - 210) \text{ psia}} \right)_{h=-10.564 \text{ Btu/lbm}} = \frac{(499.703 - 500.296) \text{ R}}{(190 - 210) \text{ psia}} = \mathbf{0.0297 \text{ R/psia}}$$

(b) The enthalpy of nitrogen at 2000 psia and 400 R is, from EES,  $h = -55.321$  Btu/lbm. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left( \frac{\partial T}{\partial P} \right)_h \cong \left( \frac{\Delta T}{\Delta P} \right)_{h=-55.321 \text{ Btu/lbm}}$$

Considering a throttling process from 2010 psia to 1990 psia at  $h = -55.321$  Btu/lbm, the Joule-Thomson coefficient is determined to be

$$\mu = \left( \frac{T_{1999 \text{ psia}} - T_{2001 \text{ psia}}}{(1990 - 2010) \text{ psia}} \right)_{h=-55.321 \text{ Btu/lbm}} = \frac{(399.786 - 400.213) \text{ R}}{(1990 - 2010) \text{ psia}} = \mathbf{0.0213 \text{ R/psia}}$$

**12-62E EES** Problem 12-61E is reconsidered. The Joule-Thompson coefficient for nitrogen over the pressure range 100 to 1500 psia at the enthalpy values 100, 175, and 225 Btu/lbm is to be plotted.

**Analysis** The problem is solved using EES, and the results are tabulated and plotted below.

```

Gas$ = 'Nitrogen'
{P_ref=200 [psia]
T_ref=500 [R]
P= P_ref}
h=50 [Btu/lbm]
{h=enthalpy(Gas$, T=T_ref, P=P_ref)}
dP = 10 [psia]
T = temperature(Gas$, P=P, h=h)
P[1] = P + dP
P[2] = P - dP
T[1] = temperature(Gas$, P=P[1], h=h)
T[2] = temperature(Gas$, P=P[2], h=h)
Mu = DELTAT/DELTAP "Approximate the differential by differences about the state at h=const."
DELTAT=T[2]-T[1]
DELTAP=P[2]-P[1]

```

**h = 100 Btu/lbm**

| P [psia] | $\mu$ [R/psia] |
|----------|----------------|
| 100      | 0.003675       |
| 275      | 0.003277       |
| 450      | 0.002899       |

| 1500     | 0.0009699      |

**12-63** The Joule-Thomson coefficient of refrigerant-134a at a specified state is to be estimated.

**Analysis** The enthalpy of refrigerant-134a at 0.7 MPa and  $T = 50^\circ\text{C}$  is  $h = 288.53 \text{ kJ/kg}$ . Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left( \frac{\partial T}{\partial P} \right)_h \cong \left( \frac{\Delta T}{\Delta P} \right)_{h=288.53 \text{ kJ/kg}}$$

Considering a throttling process from 0.8 MPa to 0.6 MPa at  $h = 288.53 \text{ kJ/kg}$ , the Joule-Thomson coefficient is determined to be

$$\mu = \left( \frac{T_{0.8 \text{ MPa}} - T_{0.6 \text{ MPa}}}{(0.8 - 0.6) \text{ MPa}} \right)_{h=288.53 \text{ kJ/kg}} = \frac{(51.81 - 48.19)^\circ\text{C}}{(0.8 - 0.6) \text{ MPa}} = \mathbf{18.1^\circ\text{C/MPa}}$$

**12-64** Steam is throttled slightly from 1 MPa and  $300^\circ\text{C}$ . It is to be determined if the temperature of the steam will increase, decrease, or remain the same during this process.

**Analysis** The enthalpy of steam at 1 MPa and  $T = 300^\circ\text{C}$  is  $h = 3051.6 \text{ kJ/kg}$ . Now consider a throttling process from this state to 0.8 MPa, which is the next lowest pressure listed in the tables. The temperature of the steam at the end of this throttling process will be

$$\left. \begin{array}{l} P = 0.8 \text{ MPa} \\ h = 3051.6 \text{ kJ/kg} \end{array} \right\} T_2 = 297.52^\circ\text{C}$$

Therefore, the temperature will **decrease**.

**12-65** It is to be demonstrated that the Joule-Thomson coefficient is given by  $\mu = \frac{T^2}{c_p} \left( \frac{\partial(\nu/T)}{\partial T} \right)_P$ .

**Analysis** From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[ T \left( \frac{\partial \nu}{\partial T} \right)_P - \nu \right]$$

Expanding the partial derivative of  $\nu/T$  produces

$$\left( \frac{\partial \nu/T}{\partial T} \right)_P = \frac{1}{T} \left( \frac{\partial \nu}{\partial T} \right)_P - \frac{\nu}{T^2}$$

When this is multiplied by  $T^2$ , the right-hand side becomes the same as the bracketed quantity above. Then,

$$\mu = \frac{T^2}{c_p} \left( \frac{\partial(\nu/T)}{\partial T} \right)_P$$

**12-66** The most general equation of state for which the Joule-Thomson coefficient is always zero is to be determined.

**Analysis** From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[ T \left( \frac{\partial \nu}{\partial T} \right)_p - \nu \right]$$

When  $\mu = 0$ , this equation becomes

$$\left( \frac{\partial \nu}{\partial T} \right)_p = \frac{\nu}{T}$$

This can only be satisfied by an equation of state of the form

$$\frac{\nu}{T} = f(P)$$

where  $f(P)$  is an arbitrary function of the pressure.

**12-67E** The Joule-Thomson coefficient of refrigerant-134a at a given state is to be estimated.

**Analysis** The Joule-Thomson coefficient is defined as

$$\mu = \left( \frac{\partial T}{\partial P} \right)_h$$

We use a finite difference approximation as

$$\mu \cong \frac{T_2 - T_1}{P_2 - P_1} \quad (\text{at constant enthalpy})$$

At the given state (we call it state 1), the enthalpy of R-134a is

$$\left. \begin{array}{l} P_1 = 30 \text{ psia} \\ T_1 = 20^\circ\text{F} \end{array} \right\} h_1 = 106.27 \text{ Btu/lbm} \quad (\text{Table A-13E})$$

The second state will be selected for a pressure of 20 psia. At this pressure and the same enthalpy, we have

$$\left. \begin{array}{l} P_2 = 20 \text{ psia} \\ h_2 = h_1 = 106.27 \text{ Btu/lbm} \end{array} \right\} T_2 = 15.65^\circ\text{F} \quad (\text{Table A-13E})$$

Substituting,

$$\mu \cong \frac{T_2 - T_1}{P_2 - P_1} = \frac{(15.65 - 20)\text{R}}{(20 - 30)\text{psia}} = \mathbf{0.435 \text{ R/psia}}$$

**12-68** The Joule-Thomson coefficient of refrigerant-134a at a given state is to be estimated.

**Analysis** The Joule-Thomson coefficient is defined as

$$\mu = \left( \frac{\partial T}{\partial P} \right)_h$$

We use a finite difference approximation as

$$\mu \cong \frac{T_2 - T_1}{P_2 - P_1} \quad (\text{at constant enthalpy})$$

At the given state (we call it state 1), the enthalpy of R-134a is

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ T_1 = 20^\circ\text{C} \end{array} \right\} h_1 = 270.18 \text{ kJ/kg} \quad (\text{Table A - 13})$$

The second state will be selected for a pressure of 180 kPa. At this pressure and the same enthalpy, we have

$$\left. \begin{array}{l} P_2 = 180 \text{ kPa} \\ h_2 = h_1 = 270.18 \text{ kJ/kg} \end{array} \right\} T_2 = 19.51^\circ\text{C} \quad (\text{Table A - 13})$$

Substituting,

$$\mu \cong \frac{T_2 - T_1}{P_2 - P_1} = \frac{(19.51 - 20)\text{K}}{(180 - 200)\text{kPa}} = \mathbf{0.0245 \text{ K/kPa}}$$

**12-69** The equation of state of a gas is given by  $\nu = \frac{RT}{P} - \frac{a}{T} + b$ . An equation for the Joule-Thomson coefficient inversion line using this equation is to be derived.

**Analysis** From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[ T \left( \frac{\partial \nu}{\partial T} \right)_p - \nu \right]$$

When  $\mu = 0$  as it does on the inversion line, this equation becomes

$$T \left( \frac{\partial \nu}{\partial T} \right)_p = \nu$$

Using the equation of state to evaluate the partial derivative,

$$\left( \frac{\partial \nu}{\partial T} \right)_p = \frac{R}{P} + \frac{a}{T^2}$$

Substituting this result into the previous expression produces

$$T \left( \frac{R}{P} + \frac{a}{T^2} \right) = \frac{RT}{P} - \frac{a}{T} + b$$

Solving this for the temperature gives

$$T = \frac{2a}{b}$$

as the condition along the inversion line.

## The $\Delta h$ , $\Delta u$ , and $\Delta s$ of Real Gases

**12-70C** It is the variation of enthalpy with pressure at a fixed temperature.

**12-71C** As  $P_R$  approaches zero, the gas approaches ideal gas behavior. As a result, the deviation from ideal gas behavior diminishes.

**12-72C** So that a single chart can be used for all gases instead of a single particular gas.

**12-73** The errors involved in the enthalpy and internal energy of  $\text{CO}_2$  at 350 K and 10 MPa if it is assumed to be an ideal gas are to be determined.

**Analysis** (a) The enthalpy departure of  $\text{CO}_2$  at the specified state is determined from the generalized chart to be (Fig. A-29)

$$\text{and } \left. \begin{aligned} T_R &= \frac{T}{T_{\text{cr}}} = \frac{350}{304.2} = 1.151 \\ P_R &= \frac{P}{P_{\text{cr}}} = \frac{10}{7.39} = 1.353 \end{aligned} \right\} \longrightarrow Z_h = \frac{(\bar{h}_{\text{ideal}} - \bar{h})_{T,P}}{R_u T_{\text{cr}}} = 1.5$$

$\text{CO}_2$   
 350 K  
 10 MPa

Thus,

$$\bar{h} = \bar{h}_{\text{ideal}} - Z_h R_u T_{\text{cr}} = 11,351 - [(1.5)(8.314)(304.2)] = 7,557 \text{ kJ/kmol}$$

and,

$$\text{Error} = \frac{(\bar{h}_{\text{ideal}} - \bar{h})_{T,P}}{\bar{h}} = \frac{11,351 - 7,557}{7,557} = \mathbf{50.2\%}$$

(b) At the calculated  $T_R$  and  $P_R$  the compressibility factor is determined from the compressibility chart to be  $Z = 0.65$ . Then using the definition of enthalpy, the internal energy is determined to be

$$\bar{u} = \bar{h} - P\bar{v} = \bar{h} - ZR_u T = 7557 - [(0.65)(8.314)(350)] = 5,666 \text{ kJ/kmol}$$

and,

$$\text{Error} = \frac{\bar{u}_{\text{ideal}} - \bar{u}}{\bar{u}} = \frac{8,439 - 5,666}{5,666} = \mathbf{48.9\%}$$

**12-74** The enthalpy and entropy changes of nitrogen during a process are to be determined assuming ideal gas behavior and using generalized charts.

**Analysis** (a) Using data from the ideal gas property table of nitrogen (Table A-18),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 9306 - 6,537 = \mathbf{2769 \text{ kJ/kmol}}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 193.562 - 183.289 - 8.314 \times \ln \frac{12}{6} = \mathbf{4.510 \text{ kJ/kmol} \cdot \text{K}}$$

(b) The enthalpy and entropy departures of nitrogen at the specified states are determined from the generalized charts to be (Figs. A-29, A-30)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{225}{126.2} = 1.783 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{6}{3.39} = 1.770 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.6 \text{ and } Z_{s1} = 0.25$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{320}{126.2} = 2.536 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{12}{3.39} = 2.540 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.4 \text{ and } Z_{s2} = 0.15$$

Substituting,

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= R_u T_{\text{cr}} (Z_{h1} - Z_{h2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314)(126.2)(0.6 - 0.4) + 2769 \\ &= \mathbf{2979 \text{ kJ/kmol}} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= R_u (Z_{s1} - Z_{s2}) + (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} \\ &= (8.314)(0.25 - 0.15) + 4.510 \\ &= \mathbf{5.341 \text{ kJ/kmol} \cdot \text{K}} \end{aligned}$$

**12-75** Methane is compressed adiabatically by a steady-flow compressor. The required power input to the compressor is to be determined using the generalized charts.

**Assumptions** 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

**Analysis** The steady-flow energy balance equation for this compressor can be expressed as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{W}_{\text{C,in}} + \dot{m}h_1 = \dot{m}h_2$$

$$\dot{W}_{\text{C,in}} = \dot{m}(h_2 - h_1)$$

The enthalpy departures of  $\text{CH}_4$  at the specified states are determined from the generalized charts to be (Fig. A-29)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{263}{191.1} = 1.376 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{2}{4.64} = 0.431 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.21$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{383}{191.1} = 2.00 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{10}{4.64} = 2.155 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.50$$

Thus,

$$\begin{aligned} h_2 - h_1 &= RT_{\text{cr}}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} \\ &= (0.5182)(191.1)(0.21 - 0.50) + 2.2537(110 - (-10)) \\ &= 241.7 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$\dot{W}_{\text{C,in}} = (0.55 \text{ kg/s})(241.7 \text{ kJ/kg}) = \mathbf{133 \text{ kW}}$$

**12-76E** The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

**Properties** The properties of water are (Table A-1E)

$$M = 18.015 \text{ lbm/lbmol}, T_{\text{cr}} = 1164.8 \text{ R}, P_{\text{cr}} = 3200 \text{ psia}$$

**Analysis** (a) Using data from the ideal gas property table of water vapor (Table A-23E),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 12,178.8 - 17,032.5 = -4853.7 \text{ Btu/lbmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 53.556 - 56.411 - 1.9858 \times \ln \frac{1000}{3000} = -0.6734 \text{ Btu/lbmol} \cdot \text{R}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{1960}{1164.8} = 1.683 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{3000}{3200} = 0.9375 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.387 \text{ and } Z_{s1} = 0.188$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{1460}{1164.8} = 1.253 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{1000}{3200} = 0.3125 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.233 \text{ and } Z_{s2} = 0.134$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= -4853.7 - (1.9858)(1164.8)(0.233 - 0.387) = -4497.5 \text{ Btu/lbmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= -0.6734 - (1.9858)(0.134 - 0.188) = -0.5662 \text{ Btu/lbmol} \cdot \text{R} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{-4497.5 \text{ Btu/lbmol}}{18.015 \text{ lbm/lbmol}} = \mathbf{-249.7 \text{ Btu/lbm}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{-0.5662 \text{ Btu/lbmol} \cdot \text{R}}{18.015 \text{ lbm/lbmol}} = \mathbf{-0.0314 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(b) Using water tables (Table A-6E)

$$\begin{aligned} \left. \begin{aligned} P_1 &= 3000 \text{ psia} \\ T_1 &= 1500^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_1 &= 1764.6 \text{ Btu/lbm} \\ s_1 &= 1.6883 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \\ \left. \begin{aligned} P_2 &= 1000 \text{ psia} \\ T_2 &= 1000^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_2 &= 1506.2 \text{ Btu/lbm} \\ s_2 &= 1.6535 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \end{aligned}$$

The enthalpy and entropy changes are

$$\begin{aligned} h_2 - h_1 &= 1506.2 - 1764.6 = \mathbf{-258.4 \text{ Btu/lbm}} \\ s_2 - s_1 &= 1.6535 - 1.6883 = \mathbf{-0.0348 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

**12-77** The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

**Properties** The properties of water are (Table A-1)

$$M = 18.015 \text{ kg/kmol}, T_{\text{cr}} = 647.1 \text{ K}, P_{\text{cr}} = 22.06 \text{ MPa}$$

**Analysis** Using data from the ideal gas property table of water vapor (Table A-23),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 23,082 - 30,754 = -7672 \text{ kJ/kmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 217.141 - 227.109 - 8.314 \times \ln \frac{500}{1000} = -4.2052 \text{ kJ/kmol} \cdot \text{K}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{873}{647.1} = 1.349 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{22.06} = 0.0453 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.0288 \text{ and } Z_{s1} = 0.0157$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{673}{647.1} = 1.040 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{0.5}{22.06} = 0.0227 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.0223 \text{ and } Z_{s2} = 0.0146$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= -7672 - (8.314)(647.1)(0.0223 - 0.0288) = -7637 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= -4.2052 - (8.314)(0.0146 - 0.0157) = -4.1961 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{-7637 \text{ kJ/kmol}}{18.015 \text{ kg/kmol}} = \mathbf{-423.9 \text{ kJ/kg}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{-4.1961 \text{ kJ/kmol} \cdot \text{K}}{18.015 \text{ kg/kmol}} = \mathbf{-0.2329 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The inlet and exit state properties of water vapor from Table A-6 are

$$\left. \begin{aligned} P_1 &= 1000 \text{ kPa} \\ T_1 &= 600^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &= 3698.6 \text{ kJ/kg} \\ s_1 &= 8.0311 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_2 &= 500 \text{ kPa} \\ T_2 &= 400^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_2 &= 3272.4 \text{ kJ/kg} \\ s_2 &= 7.7956 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The enthalpy and entropy changes are

$$\begin{aligned} h_2 - h_1 &= 3272.4 - 3698.6 = \mathbf{-426.2 \text{ kJ/kg}} \\ s_2 - s_1 &= 7.7956 - 8.0311 = \mathbf{-0.2355 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

**12-78** The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

**Properties** The properties of water are (Table A-1)

$$M = 18.015 \text{ kg/kmol}, T_{\text{cr}} = 647.1 \text{ K}, P_{\text{cr}} = 22.06 \text{ MPa}$$

**Analysis** (a) The pressure of water vapor during this process is

$$P_1 = P_2 = P_{\text{sat}@300^\circ\text{C}} = 8588 \text{ kPa}$$

Using data from the ideal gas property table of water vapor (Table A-23),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 34,775 - 19,426 = 15,349 \text{ kJ/kmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 231.473 - 211.263 - 0 = 20.210 \text{ kJ/kmol} \cdot \text{K}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{573}{647.1} = 0.885 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{8.588}{22.06} = 0.389 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.609 \text{ and } Z_{s1} = 0.481$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{973}{647.1} = 1.504 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{8.588}{22.06} = 0.389 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.204 \text{ and } Z_{s2} = 0.105$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= 15,349 - (8.314)(647.1)(0.204 - 0.609) = 17,528 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= 20.210 - (8.314)(0.105 - 0.481) = 23.336 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{17,528 \text{ kJ/kmol}}{18.015 \text{ kg/kmol}} = \mathbf{973.0 \text{ kJ/kg}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{23.336 \text{ kJ/kmol} \cdot \text{K}}{18.015 \text{ kg/kmol}} = \mathbf{1.2954 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

(b) The inlet and exit state properties of water vapor from Table A-6 are

$$\left. \begin{aligned} T_1 &= 300^\circ\text{C} \\ x_1 &= 1 \end{aligned} \right\} \begin{aligned} h_1 &= 2749.6 \text{ kJ/kg} \\ s_1 &= 5.7059 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_2 &= 8588 \text{ kPa} \\ T_2 &= 700^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_2 &= 3878.6 \text{ kJ/kg} \\ s_2 &= 7.2465 \text{ kJ/kg} \cdot \text{K} \end{aligned} \quad (\text{from EES})$$

The enthalpy and entropy changes are

$$\begin{aligned} h_2 - h_1 &= 3878.6 - 2749.6 = \mathbf{1129 \text{ kJ/kg}} \\ s_2 - s_1 &= 7.2465 - 5.7059 = \mathbf{1.5406 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

**12-79** Propane is to be adiabatically and reversibly compressed in a steady-flow device. The specific work required for this compression is to be determined using the departure charts and treating the propane as an ideal gas with temperature variable specific heats.

**Properties** The properties of propane are (Table A-1)

$$M = 44.097 \text{ kg/kmol}, R = 0.1885 \text{ kJ/kg} \cdot \text{K}, T_{\text{cr}} = 370 \text{ K}, P_{\text{cr}} = 4.26 \text{ MPa}$$

**Analysis** The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. When the entropy change equation is integrated with variable specific heats, it becomes

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1}$$

When the expression of Table A-2c is substituted for  $c_p$  and the integration performed, we obtain

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left( \frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \\ 0 &= -4.04 \ln \frac{T_2}{373} + 30.48 \left( \frac{T_2}{100} - 3.73 \right) - 0.786 \left[ \left( \frac{T_2}{100} \right)^2 - 3.73^2 \right] + 0.01058 \left[ \left( \frac{T_2}{100} \right)^3 - 3.73^3 \right] \\ &\quad - (8.314) \ln \frac{4000}{500} \end{aligned}$$

Solving this equation by EES or an iterative solution by hand gives

$$T_2 = 446 \text{ K}$$

When an energy balance is applied to the compressor, it becomes

$$\begin{aligned} \bar{w}_{\text{in}} &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \int_1^2 c_p dT = \int_1^2 (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= -4.04(446 - 373) + 0.1524(446^2 - 373^2) - 52.4(4.46^3 - 3.73^3) + 0.7935(4.46^4 - 3.73^4) \\ &= 7048 \text{ kJ/kmol} \end{aligned}$$

The work input per unit mass basis is

$$w_{\text{in}} = \frac{\bar{w}_{\text{in}}}{M} = \frac{7048 \text{ kJ/kmol}}{44.097 \text{ kg/kmol}} = \mathbf{159.8 \text{ kJ/kg}}$$

The enthalpy departures of propane at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{0.5}{4.26} = 0.117 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.124$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{446}{370} = 1.205 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.826$$

The work input (i.e., enthalpy change) is determined to be

$$\begin{aligned} w_{in} &= h_2 - h_1 = (h_2 - h_1)_{ideal} - RT_{cr}(Z_{h2} - Z_{h1}) \\ &= 159.8 - (0.1885)(370)(0.826 - 0.124) \\ &= \mathbf{110.8 \text{ kJ/kg}} \end{aligned}$$

**12-80E** Oxygen is to be adiabatically and reversibly expanded in a nozzle. The exit velocity is to be determined using the departure charts and treating the oxygen as an ideal gas with temperature variable specific heats.

**Properties** The properties of oxygen are (Table A-1)

$$M = 31.999 \text{ lbm/lbmol}, R = 0.06206 \text{ Btu/lbm} \cdot \text{R}, T_{\text{cr}} = 278.6 \text{ R}, P_{\text{cr}} = 736 \text{ psia}$$

**Analysis** The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. From the entropy change equation for an ideal gas with variable specific heats:

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = 0$$

$$s_2^\circ - s_1^\circ = R_u \ln \frac{P_2}{P_1} = (1.9858) \ln \frac{70}{200} = -2.085 \text{ Btu/lbmol} \cdot \text{R}$$

Then from Table A-19E,

$$T_1 = 1060 \text{ R} \longrightarrow \bar{h}_{1,\text{ideal}} = 7543.6 \text{ Btu/lbmol}, s_1^\circ = 53.921 \text{ Btu/lbmol} \cdot \text{R}$$

$$s_2^\circ = s_1^\circ - 2.085 = 53.921 - 2.085 = 51.836 \text{ Btu/lbmol} \cdot \text{R}$$

$$s_2^\circ = 51.836 \text{ Btu/lbmol} \cdot \text{R} \longrightarrow T_2 = 802 \text{ R}, \bar{h}_{2,\text{ideal}} = 5614.1 \text{ Btu/lbmol}$$

The enthalpy change per mole basis is

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 5614.1 - 7543.6 = -1929.5 \text{ Btu/lbmol}$$

The enthalpy change per mass basis is

$$(h_2 - h_1)_{\text{ideal}} = \frac{(\bar{h}_2 - \bar{h}_1)_{\text{ideal}}}{M} = \frac{-1929.5 \text{ Btu/lbmol}}{31.999 \text{ lbm/lbmol}} = -60.30 \text{ Btu/lbm}$$

An energy balance on the nozzle gives

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}(h_1 + V_1^2 / 2) = \dot{m}(h_2 + V_2^2 / 2)$$

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2$$

Solving for the exit velocity,

$$V_2 = [V_1^2 + 2(h_1 - h_2)]^{0.5} = \left[ (0 \text{ ft/s})^2 + 2(60.30 \text{ Btu/lbm}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \right]^{0.5} = \mathbf{1738 \text{ ft/s}}$$

The enthalpy departures of oxygen at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{1060}{278.6} = 3.805 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{200}{736} = 0.272 \end{aligned} \right\} Z_{h1} = 0.000759 \quad \left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{802}{278.6} = 2.879 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{70}{736} = 0.0951 \end{aligned} \right\} Z_{h2} = 0.00894$$

The enthalpy change is

$$\begin{aligned} h_2 - h_1 &= (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= -60.30 \text{ Btu/lbm} - (0.06206 \text{ Btu/lbm} \cdot \text{R})(278.6 \text{ R})(0.00894 - 0.000759) \\ &= -60.44 \text{ Btu/lbm} \end{aligned}$$

The exit velocity is

$$V_2 = [V_1^2 + 2(h_1 - h_2)]^{0.5} = \left[ (0 \text{ ft/s})^2 + 2(60.44 \text{ Btu/lbm}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \right]^{0.5} = \mathbf{1740 \text{ ft/s}}$$

**12-81 [Also solved by EES on enclosed CD]** Propane is compressed isothermally by a piston-cylinder device. The work done and the heat transfer are to be determined using the generalized charts.

**Assumptions 1** The compression process is quasi-equilibrium. **2** Kinetic and potential energy changes are negligible.

**Analysis (a)** The enthalpy departure and the compressibility factors of propane at the initial and the final states are determined from the generalized charts to be (Figs. A-29, A-15)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{1}{4.26} = 0.235 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.28 \text{ and } Z_1 = 0.92$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \longrightarrow Z_{h2} = 1.8 \text{ and } Z_2 = 0.50$$

Treating propane as a real gas with  $Z_{avg} = (Z_1 + Z_2)/2 = (0.92 + 0.50)/2 = 0.71$ ,

$$Pv = ZRT \cong Z_{avg} RT = C = \text{constant}$$

Then the boundary work becomes

$$\begin{aligned} w_{b,in} &= -\int_1^2 P d\nu = -\int_1^2 \frac{C}{\nu} d\nu = -C \ln \frac{\nu_2}{\nu_1} = Z_{avg} RT \ln \frac{Z_2 RT / P_2}{Z_1 RT / P_1} = -Z_{ave} RT \ln \frac{Z_2 P_1}{Z_1 P_2} \\ &= -(0.71)(0.1885 \text{ kJ/kg} \cdot \text{K})(373 \text{ K}) \ln \frac{(0.50)(1)}{(0.92)(4)} = \mathbf{99.6 \text{ kJ/kg}} \end{aligned}$$

Also,

$$\begin{aligned} h_2 - h_1 &= RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{ideal} = (0.1885)(370)(0.28 - 1.8) + 0 = -106 \text{ kJ/kg} \\ u_2 - u_1 &= (h_2 - h_1) - R(Z_2 T_2 - Z_1 T_1) = -106 - (0.1885)[(0.5)(373) - (0.92)(373)] = -76.5 \text{ kJ/kg} \end{aligned}$$

Then the heat transfer for this process is determined from the closed system energy balance to be

$$\begin{aligned} E_{in} - E_{out} &= \Delta E_{system} \\ q_{in} + w_{b,in} &= \Delta u = u_2 - u_1 \\ q_{in} &= (u_2 - u_1) - w_{b,in} = -76.5 - 99.6 = -176.1 \text{ kJ/kg} \rightarrow q_{out} = 176.1 \text{ kJ/kg} \end{aligned}$$

**12-82 EES** Problem 12-81 is reconsidered. This problem is to be extended to compare the solutions based on the ideal gas assumption, generalized chart data and real fluid (EES) data. Also, the solution is to be extended to carbon dioxide, nitrogen and methane.

**Analysis** The problem is solved using EES, and the solution is given below.

```

**12-83** Propane is compressed isothermally by a piston-cylinder device. The exergy destruction associated with this process is to be determined.

**Assumptions** 1 The compression process is quasi-equilibrium. 2 Kinetic and potential energy changes are negligible.

**Properties** The gas constant of propane is  $R = 0.1885 \text{ kJ/kg} \cdot \text{K}$  (Table A-1).

**Analysis** The exergy destruction is determined from its definition  $x_{\text{destroyed}} = T_0 s_{\text{gen}}$  where the entropy generation is determined from an entropy balance on the contents of the cylinder. It gives

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$

$$-\frac{Q_{\text{out}}}{T_{b,\text{surr}}} + S_{\text{gen}} = m(s_2 - s_1) \rightarrow s_{\text{gen}} = (s_2 - s_1) + \frac{q_{\text{out}}}{T_{\text{surr}}}$$

where

$$\Delta S_{\text{sys}} = s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}}$$

$$(s_2 - s_1)_{\text{ideal}} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = 0 - 0.1885 \ln \frac{4}{1} = -0.261 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{4.26} = 0.235 \end{aligned} \right\} \longrightarrow Z_{s1} = 0.21$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \longrightarrow Z_{s2} = 1.5$$

Thus,

$$\Delta S_{\text{sys}} = s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} = (0.1885)(0.21 - 1.5) - 0.261 = -0.504 \text{ kJ/kg} \cdot \text{K}$$

and

$$x_{\text{destroyed}} = T_0 s_{\text{gen}} = T_0 \left( (s_2 - s_1) + \frac{q_{\text{out}}}{T_{\text{surr}}} \right)$$

$$= (303 \text{ K}) \left( -0.504 + \frac{176.1 \text{ kJ/kg}}{303 \text{ K}} \right) \text{ kJ/kg} \cdot \text{K}$$

$$= 23.4 \text{ kJ/kg}$$

**12-84E** Propane is compressed isothermally by a piston-cylinder device. The work done and the heat transfer are to be determined using the generalized charts.

**Assumptions** 1 The compression process is quasi-equilibrium. 2 Kinetic and potential energy changes are negligible. 3 The device is well-insulated and thus heat transfer is negligible.

**Analysis** (a) The enthalpy departure and the compressibility factors of propane at the initial and the final states are determined from the generalized charts to be (Figs. A-29, A-15)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{660}{665.9} = 0.991 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{200}{617} = 0.324 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.37 \text{ and } Z_1 = 0.88$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{660}{665.9} = 0.991 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{800}{617} = 1.297 \end{aligned} \right\} \longrightarrow Z_{h2} = 4.2 \text{ and } Z_2 = 0.22$$

Treating propane as a real gas with  $Z_{avg} = (Z_1 + Z_2)/2 = (0.88 + 0.22)/2 = 0.55$ ,

$$Pv = ZRT \cong Z_{avg} RT = C = \text{constant}$$

Then the boundary work becomes

$$\begin{aligned} w_{b,in} &= -\int_1^2 P dv = -\int_1^2 \frac{C}{v} dv = -C \ln \frac{v_2}{v_1} = -Z_{avg} RT \ln \frac{Z_2 RT / P_2}{Z_1 RT / P_1} = -Z_{avg} RT \ln \frac{Z_2 P_1}{Z_1 P_2} \\ &= -(0.55)(0.04504 \text{ Btu/lbm} \cdot \text{R})(660 \text{ R}) \ln \frac{(0.22)(200)}{(0.88)(800)} \\ &= \mathbf{45.3 \text{ Btu/lbm}} \end{aligned}$$

Also,

$$\begin{aligned} h_2 - h_1 &= RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{ideal}^{\phi_0} \\ &= (0.04504)(665.9)(0.37 - 4.2) + 0 = -114.9 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned} u_2 - u_1 &= (h_2 - h_1) - R(Z_2 T_2 - Z_1 T_1) \\ &= -114.9 - (0.04504)[(0.22)(660) - (0.88)(660)] = -95.3 \text{ Btu/lbm} \end{aligned}$$

Then the heat transfer for this process is determined from the closed system energy balance equation to be

$$\begin{aligned} E_{in} - E_{out} &= \Delta E_{system} \\ q_{in} + w_{b,in} &= \Delta u = u_2 - u_1 \\ q_{in} &= (u_2 - u_1) - w_{b,in} = -95.3 - 45.3 = -140.6 \text{ Btu/lbm} \rightarrow q_{out} = \mathbf{140.6 \text{ Btu/lbm}} \end{aligned}$$

**12-85** A paddle-wheel placed in a well-insulated rigid tank containing oxygen is turned on. The final pressure in the tank and the paddle-wheel work done during this process are to be determined.

**Assumptions** 1 The tank is well-insulated and thus heat transfer is negligible. 2 Kinetic and potential energy changes are negligible.

**Properties** The gas constant of  $O_2$  is  $R = 0.2598 \text{ kJ/kg}\cdot\text{K}$  (Table A-1).

**Analysis** (a) The compressibility factor of oxygen at the initial state is determined from the generalized chart to be

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{220}{154.8} = 1.42 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{10}{5.08} = 1.97 \end{aligned} \right\} \longrightarrow Z_1 = 0.80 \text{ and } Z_{h1} = 1.15$$

Then,

$$\begin{aligned} P\nu &= ZRT \longrightarrow \nu_1 = \frac{(0.8)(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(220 \text{ K})}{10,000 \text{ kPa}} = 0.00457 \text{ m}^3/\text{kg} \\ m &= \frac{\nu}{\nu_1} = \frac{0.08 \text{ m}^3}{0.00457 \text{ m}^3/\text{kg}} = 17.5 \text{ kg} \end{aligned}$$

The specific volume of oxygen remains constant during this process,  $\nu_2 = \nu_1$ . Thus,

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{250}{154.8} = 1.615 \\ \nu_{R2} &= \frac{\nu_2}{RT_{cr}/P_{cr}} = \frac{0.00457 \text{ m}^3/\text{kg}}{(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(154.8 \text{ K})/(5080 \text{ kPa})} = 0.577 \end{aligned} \right\} \begin{aligned} Z_2 &= 0.87 \\ Z_{h2} &= 1.0 \\ P_{R2} &= 2.4 \end{aligned}$$

$$P_2 = P_{R2}P_{cr} = (2.4)(5080) = \mathbf{12,190 \text{ kPa}}$$

(b) The energy balance relation for this closed system can be expressed as

$$\begin{aligned} E_{in} - E_{out} &= \Delta E_{\text{system}} \\ W_{in} &= \Delta U = m(u_2 - u_1) \\ W_{in} &= m[h_2 - h_1 - (P_2\nu_2 - P_1\nu_1)] = m[h_2 - h_1 - R(Z_2T_2 - Z_1T_1)] \end{aligned}$$

where

$$\begin{aligned} h_2 - h_1 &= RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} \\ &= (0.2598)(154.8)(1.15 - 1) + (7275 - 6404) / 32 \\ &= 33.25 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$W_{in} = (17.5 \text{ kg})[33.25 - (0.2598 \text{ kJ/kg}\cdot\text{K})\{(0.87)(250) - (0.80)(220)\}\text{K}] = \mathbf{393 \text{ kJ}}$$

**12-86** The heat transfer and entropy changes of CO<sub>2</sub> during a process are to be determined assuming ideal gas behavior, using generalized charts, and real fluid (EES) data.

**Analysis** The temperature at the final state is

$$T_2 = T_1 \frac{P_2}{P_1} = (100 + 273 \text{ K}) \frac{8 \text{ MPa}}{1 \text{ MPa}} = 2984 \text{ K}$$

Using data from the ideal gas property table of CO<sub>2</sub> (Table A-20),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 161,293 - 12,269 = 149,024 \text{ kJ/kmol}$$

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 333.770 - 222.367 - 8.314 \times \ln \frac{8}{1} = 94.115 \text{ kJ/kmol} \cdot \text{K}$$

$$(h_2 - h_1)_{\text{ideal}} = \frac{(\bar{h}_2 - \bar{h}_1)_{\text{ideal}}}{M} = \frac{149,024 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = 3386.9 \text{ kJ/kg}$$

The heat transfer is determined from an energy balance noting that there is no work interaction

$$q_{\text{ideal}} = (u_2 - u_1)_{\text{ideal}} = (h_2 - h_1)_{\text{ideal}} - R(T_2 - T_1) \\ = 3386.9 \text{ kJ/kg} - (0.1889 \text{ kJ/kg} \cdot \text{K})(2984 - 373) = \mathbf{2893.7 \text{ kJ/kg}}$$

The entropy change is

$$\Delta s_{\text{ideal}} = (s_2 - s_1)_{\text{ideal}} = \frac{(\bar{s}_2 - \bar{s}_1)_{\text{ideal}}}{M} = \frac{94.115 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = \mathbf{2.1390 \text{ kJ/kg} \cdot \text{K}}$$

The compressibility factor and the enthalpy and entropy departures of CO<sub>2</sub> at the specified states are determined from the generalized charts to be (we used EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{304.2} = 1.226 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{7.39} = 0.135 \end{aligned} \right\} \longrightarrow Z_1 = 0.976, Z_{h1} = 0.1028 \text{ and } Z_{s1} = 0.05987$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{2985}{304.2} = 9.813 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{8}{7.39} = 1.083 \end{aligned} \right\} \longrightarrow Z_2 = 1.009, Z_{h2} = -0.1144 \text{ and } Z_{s2} = -0.002685$$

Thus,

$$q_{\text{chart}} = u_2 - u_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) - Z_1 R(T_2 - T_1) \\ = 3386.9 - (0.1889)(304.2)(-0.1144 - 0.1028) - (0.976)(0.1889)(2887 - 373) = \mathbf{2935.9 \text{ kJ/kg}}$$

$$\Delta s_{\text{chart}} = (s_2 - s_1)_{\text{chart}} = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} \\ = (0.1889)(0.05987 - (-0.002685)) + 2.1390 = \mathbf{2.151 \text{ kJ/kg} \cdot \text{K}}$$

Note that the temperature at the final state in this case was determined from

$$T_2 = T_1 \frac{P_2}{P_1} \frac{Z_1}{Z_2} = (100 + 273 \text{ K}) \frac{8 \text{ MPa}}{1 \text{ MPa}} \frac{0.976}{1.009} = 2888 \text{ K}$$

The solution using EES built-in property data is as follows:

$$\left. \begin{aligned} T_1 &= 373 \text{ K} \\ P_1 &= 1 \text{ MPa} \end{aligned} \right\} \begin{aligned} v_1 &= 0.06885 \text{ m}^3/\text{kg} \\ u_1 &= -8.614 \text{ kJ/kg} \\ s_1 &= -0.2464 \text{ kJ/kg} \cdot \text{K} \end{aligned} \quad \left. \begin{aligned} P_2 &= 8 \text{ MPa} \\ v_2 &= v_1 = 0.06885 \text{ m}^3/\text{kg} \end{aligned} \right\} \begin{aligned} T_2 &= 2879 \text{ K} \\ u_2 &= 2754 \text{ kJ/kg} \\ s_2 &= 1.85 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Then

$$q_{\text{EES}} = u_2 - u_1 = 2754 - (-8.614) = \mathbf{2763 \text{ kJ/kg}}$$

$$\Delta s_{\text{EES}} = (s_2 - s_1)_{\text{EES}} = s_2 - s_1 = 1.85 - (-0.2464) = \mathbf{2.097 \text{ kJ/kg} \cdot \text{K}}$$

## Review Problems

**12-87** For  $\beta \geq 0$ , it is to be shown that at every point of a single-phase region of an  $h$ - $s$  diagram, the slope of a constant-pressure line is greater than the slope of a constant-temperature line, but less than the slope of a constant-volume line.

**Analysis** It is given that  $\beta > 0$ .

Using the  $Tds$  relation:  $dh = T ds + \nu dP \longrightarrow \frac{dh}{ds} = T + \nu \frac{dP}{ds}$

$$(1) P = \text{constant:} \quad \left( \frac{\partial h}{\partial s} \right)_P = T$$

$$(2) T = \text{constant:} \quad \left( \frac{\partial h}{\partial s} \right)_T = T + \nu \left( \frac{\partial P}{\partial s} \right)_T$$

But the 4th Maxwell relation:  $\left( \frac{\partial P}{\partial s} \right)_T = - \left( \frac{\partial T}{\partial \nu} \right)_P$

Substituting:  $\left( \frac{\partial h}{\partial s} \right)_T = T - \nu \left( \frac{\partial T}{\partial \nu} \right)_P = T - \frac{1}{\beta}$

Therefore, the slope of  $P = \text{constant}$  lines is **greater** than the slope of  $T = \text{constant}$  lines.

$$(3) \nu = \text{constant:} \quad \left( \frac{\partial h}{\partial s} \right)_\nu = T + \nu \left( \frac{\partial P}{\partial s} \right)_\nu \quad (a)$$

From the  $ds$  relation:  $ds = \frac{c_\nu}{T} dT + \left( \frac{\partial P}{\partial T} \right)_\nu d\nu$

Divide by  $dP$  holding  $\nu$  constant:  $\left( \frac{\partial s}{\partial P} \right)_\nu = \frac{c_\nu}{T} \left( \frac{\partial T}{\partial P} \right)_\nu$  or  $\left( \frac{\partial P}{\partial s} \right)_\nu = \frac{T}{c_\nu} \left( \frac{\partial P}{\partial T} \right)_\nu \quad (b)$

Using the properties  $P$ ,  $T$ ,  $\nu$ , the cyclic relation can be expressed as

$$\left( \frac{\partial P}{\partial T} \right)_\nu \left( \frac{\partial T}{\partial \nu} \right)_P \left( \frac{\partial \nu}{\partial P} \right)_T = -1 \longrightarrow \left( \frac{\partial P}{\partial T} \right)_\nu = - \left( \frac{\partial \nu}{\partial T} \right)_P \left( \frac{\partial P}{\partial \nu} \right)_T = (-\beta \nu) \left( \frac{1}{-\alpha \nu} \right) = \frac{\beta}{\alpha} \quad (c)$$

where we used the definitions of  $\alpha$  and  $\beta$ . Substituting (b) and (c) into (a),

$$\left( \frac{\partial h}{\partial s} \right)_\nu = T + \nu \left( \frac{\partial P}{\partial s} \right)_\nu = T + \frac{T\beta \nu}{c_\nu \alpha} > T$$

Here  $\alpha$  is positive for all phases of all substances.  $T$  is the absolute temperature that is also positive, so is  $c_\nu$ . Therefore, the second term on the right is always a positive quantity since  $\beta$  is given to be positive. Then we conclude that the slope of  $P = \text{constant}$  lines is **less** than the slope of  $\nu = \text{constant}$  lines.

**12-88** Using the cyclic relation and the first Maxwell relation, the other three Maxwell relations are to be obtained.

**Analysis** (1) Using the properties  $P$ ,  $s$ ,  $\nu$ , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial s}\right)_{\nu} \left(\frac{\partial s}{\partial \nu}\right)_P \left(\frac{\partial \nu}{\partial P}\right)_s = -1$$

Substituting the first Maxwell relation,  $\left(\frac{\partial T}{\partial \nu}\right)_s = -\left(\frac{\partial P}{\partial s}\right)_{\nu}$ ,

$$-\left(\frac{\partial T}{\partial \nu}\right)_s \left(\frac{\partial s}{\partial \nu}\right)_P \left(\frac{\partial \nu}{\partial P}\right)_s = -1 \longrightarrow \left(\frac{\partial T}{\partial P}\right)_s \left(\frac{\partial s}{\partial \nu}\right)_P = 1 \longrightarrow \left(\frac{\partial T}{\partial P}\right)_s = \left(\frac{\partial \nu}{\partial s}\right)_P$$

(2) Using the properties  $T$ ,  $\nu$ ,  $s$ , the cyclic relation can be expressed as

$$\left(\frac{\partial T}{\partial \nu}\right)_s \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial s}{\partial T}\right)_{\nu} = -1$$

Substituting the first Maxwell relation,  $\left(\frac{\partial T}{\partial \nu}\right)_s = -\left(\frac{\partial P}{\partial s}\right)_{\nu}$ ,

$$-\left(\frac{\partial P}{\partial s}\right)_{\nu} \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial s}{\partial T}\right)_{\nu} = -1 \longrightarrow \left(\frac{\partial P}{\partial T}\right)_{\nu} \left(\frac{\partial \nu}{\partial s}\right)_T = 1 \longrightarrow \left(\frac{\partial s}{\partial \nu}\right)_T = \left(\frac{\partial P}{\partial T}\right)_{\nu}$$

(3) Using the properties  $P$ ,  $T$ ,  $\nu$ , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial T}\right)_{\nu} \left(\frac{\partial T}{\partial \nu}\right)_P \left(\frac{\partial \nu}{\partial P}\right)_T = -1$$

Substituting the third Maxwell relation,  $\left(\frac{\partial s}{\partial \nu}\right)_T = \left(\frac{\partial P}{\partial T}\right)_{\nu}$ ,

$$\left(\frac{\partial s}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial \nu}\right)_P \left(\frac{\partial \nu}{\partial P}\right)_T = -1 \longrightarrow \left(\frac{\partial s}{\partial P}\right)_T \left(\frac{\partial T}{\partial \nu}\right)_P = -1 \longrightarrow \left(\frac{\partial s}{\partial P}\right)_T = -\left(\frac{\partial \nu}{\partial T}\right)_P$$

**12-89** It is to be shown that the slope of a constant-pressure line on an  $h$ - $s$  diagram is constant in the saturation region and increases with temperature in the superheated region.

**Analysis** For  $P = \text{constant}$ ,  $dP = 0$  and the given relation reduces to  $dh = Tds$ , which can also be expressed as

$$\left(\frac{\partial h}{\partial s}\right)_P = T$$

Thus the slope of the  $P = \text{constant}$  lines on an  $h$ - $s$  diagram is equal to the temperature.

(a) In the saturation region,  $T = \text{constant}$  for  $P = \text{constant}$  lines, and the slope remains constant.

(b) In the superheat region, the slope increases with increasing temperature since the slope is equal temperature.

**12-90** It is to be shown that

$$c_v = -T \left(\frac{\partial v}{\partial T}\right)_s \left(\frac{\partial P}{\partial T}\right)_v \quad \text{and} \quad c_p = T \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial v}{\partial T}\right)_P$$

**Analysis** Using the definition of  $c_v$ ,

$$c_v = T \left(\frac{\partial s}{\partial T}\right)_v = T \left(\frac{\partial s}{\partial P}\right)_v \left(\frac{\partial P}{\partial T}\right)_v$$

Substituting the first Maxwell relation  $\left(\frac{\partial s}{\partial P}\right)_v = -\left(\frac{\partial v}{\partial T}\right)_s$ ,

$$c_v = -T \left(\frac{\partial v}{\partial T}\right)_s \left(\frac{\partial P}{\partial T}\right)_v$$

Using the definition of  $c_p$ ,

$$c_p = T \left(\frac{\partial s}{\partial T}\right)_P = T \left(\frac{\partial s}{\partial v}\right)_P \left(\frac{\partial v}{\partial T}\right)_P$$

Substituting the second Maxwell relation  $\left(\frac{\partial s}{\partial v}\right)_P = \left(\frac{\partial P}{\partial T}\right)_s$ ,

$$c_p = T \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial v}{\partial T}\right)_P$$

**12-91** It is to be proven that for a simple compressible substance  $\left(\frac{\partial s}{\partial \nu}\right)_u = \frac{P}{T}$ .

**Analysis** The proof is simply obtained as

$$\left(\frac{\partial s}{\partial \nu}\right)_u = \frac{-\left(\frac{\partial u}{\partial \nu}\right)_s}{\left(\frac{\partial u}{\partial s}\right)_\nu} = -\frac{-P}{T} = \frac{P}{T}$$

**12-92** It is to be proven by using the definitions of pressure and temperature,  $T = \left(\frac{\partial u}{\partial s}\right)_\nu$  and  $P = -\left(\frac{\partial u}{\partial \nu}\right)_s$

that for ideal gases, the development of the constant-pressure specific heat yields  $\left(\frac{\partial h}{\partial P}\right)_T = 0$

**Analysis** The definition for enthalpy is

$$h = u + P\nu$$

Then,

$$\left(\frac{\partial h}{\partial P}\right)_T = \left(\frac{\partial u}{\partial P}\right)_T + P\left(\frac{\partial \nu}{\partial P}\right)_T + \nu\left(\frac{\partial P}{\partial P}\right)_T$$

Assume  $u = u(s, \nu)$

Then,

$$\begin{aligned} du &= \left(\frac{\partial u}{\partial s}\right)_\nu ds + \left(\frac{\partial u}{\partial \nu}\right)_s d\nu \\ \left(\frac{\partial u}{\partial P}\right)_T &= \left(\frac{\partial u}{\partial s}\right)_\nu \left(\frac{\partial s}{\partial P}\right)_T + \left(\frac{\partial u}{\partial \nu}\right)_s \left(\frac{\partial \nu}{\partial P}\right)_T \\ \left(\frac{\partial u}{\partial P}\right)_T &= T \left[ -\left(\frac{\partial \nu}{\partial T}\right)_P \right] - P \left(\frac{\partial \nu}{\partial P}\right)_T = -(T + P) \left(\frac{\partial \nu}{\partial P}\right)_T \\ \left(\frac{\partial h}{\partial P}\right)_T &= -(T + P) \left(\frac{\partial \nu}{\partial P}\right)_T + P \left(\frac{\partial \nu}{\partial P}\right)_T + \nu = -T \left(\frac{\partial \nu}{\partial P}\right)_T + \nu \end{aligned}$$

For ideal gases

$$\nu = \frac{RT}{P} \quad \text{and} \quad \left(\frac{\partial \nu}{\partial P}\right)_T = -\frac{R}{P^2}$$

Then,

$$\left(\frac{\partial h}{\partial P}\right)_T = -\frac{TR}{P} + \nu = -\nu + \nu = 0$$

**12-93** It is to be proven by using the definitions of pressure and temperature,  $T = \left( \frac{\partial u}{\partial s} \right)_{\nu}$  and  $P = - \left( \frac{\partial u}{\partial \nu} \right)_s$  that for ideal gases, the development of the constant-volume specific heat yields  $\left( \frac{\partial u}{\partial \nu} \right)_T = 0$ .

**Analysis** Assume  $u = u(s, \nu)$

Then,

$$\begin{aligned} du &= \left( \frac{\partial u}{\partial s} \right)_{\nu} ds + \left( \frac{\partial u}{\partial \nu} \right)_s d\nu \\ \left( \frac{\partial u}{\partial \nu} \right)_T &= \left( \frac{\partial u}{\partial s} \right)_{\nu} \left( \frac{\partial s}{\partial \nu} \right)_T + \left( \frac{\partial u}{\partial \nu} \right)_s \left( \frac{\partial \nu}{\partial \nu} \right)_T \\ &= T \left( \frac{\partial s}{\partial \nu} \right)_T + P \end{aligned}$$

From Maxwell equation,

$$T \left( \frac{\partial s}{\partial \nu} \right)_T + P = T \left( \frac{\partial P}{\partial T} \right)_{\nu} - P$$

For ideal gases

$$P = \frac{RT}{\nu} \quad \text{and} \quad \left( \frac{\partial P}{\partial T} \right)_{\nu} = \frac{R}{\nu}$$

Then,

$$\left( \frac{\partial u}{\partial \nu} \right)_T = T \frac{R}{\nu} - P = P - P = 0$$

**12-94** Expressions for  $h$ ,  $u$ ,  $s^\circ$ ,  $P_r$ , and  $\nu_r$  for an ideal gas whose  $c_p^\circ$  is given by

$$c_p^\circ = \sum a_i T^{i-n} + a_0 e^{\beta/T} \left( \frac{\beta/T}{e^{\beta/T} - 1} \right) \text{ are to be developed.}$$

**Analysis** The enthalpy of this substance relative to a reference state is given by

$$h = \int_{T_{\text{ref}}}^T c_p dT = \sum \frac{a_i}{i-n+1} (T^{i-n+1} - T_{\text{ref}}^{i-n+1}) + a_0 \left[ e^{\beta/T} - e^{\beta/T_{\text{ref}}} - eE_1\left(1 - \frac{\beta}{T}\right) - eE_1\left(1 - \frac{\beta}{T_{\text{ref}}}\right) \right]$$

where  $E_1(x)$  is the exponential integral function of order 1. Similarly,  $s^\circ$  is given by

$$s^\circ = \int_{T_{\text{ref}}}^T \frac{c_p}{T} dT = \sum \frac{a_i}{i-n} (T^{i-n} - T_{\text{ref}}^{i-n}) - a_0 \left[ e^{\beta/T} - e^{\beta/T_{\text{ref}}} - eE_1\left(1 - \frac{\beta}{T}\right) - eE_1\left(1 - \frac{\beta}{T_{\text{ref}}}\right) \right]$$

With these two results,

$$u = h - P\nu$$

$$P_r = e^{s^\circ/R}$$

According to the  $du$  form of Gibbs equations,

$$\frac{du}{T} = -R \frac{d\nu}{\nu}$$

Noting that for ideal gases,  $c_\nu = c_p - R$  and  $du = c_\nu dT$ , this expression reduces to

$$(c_p - R) \frac{dT}{T} = -R \frac{d\nu}{\nu}$$

When this is integrated between the reference and actual states, the result is

$$\int c_p \frac{dT}{T} - R \ln \frac{T}{T_{\text{ref}}} = -R \ln \frac{\nu}{\nu_{\text{ref}}}$$

Solving this for the specific volume ratio gives

$$\frac{\nu}{\nu_{\text{ref}}} = - \frac{\left( e^{s^\circ} - e^R \frac{T}{T_{\text{ref}}} \right)}{e^R} = - \frac{e^{s^\circ}}{e^R} + \frac{e^R \frac{T}{T_{\text{ref}}}}{e^R} = - \frac{e^{s^\circ}}{e^R} + \frac{T}{T_{\text{ref}}} = - \exp(s^\circ - R) + \frac{T}{T_{\text{ref}}}$$

The ratio of the specific volumes at two states which have the same entropy is then

$$\frac{\nu_2}{\nu_1} = \frac{\nu_{r,2}}{\nu_{r,1}} = - \exp(s_2^\circ - s_1^\circ - R) + \frac{T_2}{T_1}$$

Inspection of this result gives

$$\nu_r = - \exp(s^\circ - R) + T$$

**12-95** The  $c_p$  of nitrogen at 300 kPa and 400 K is to be estimated using the relation given and its definition, and the results are to be compared to the value listed in Table A-2b.

**Analysis** (a) We treat nitrogen as an ideal gas with  $R = 0.297 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.397$ . Note that  $PT^{k/(k-1)} = C = \text{constant}$  for the isentropic processes of ideal gases. The  $c_p$  relation is given as

$$\begin{aligned} c_p &= T \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial \nu}{\partial T} \right)_p \\ \nu &= \frac{RT}{P} \longrightarrow \left( \frac{\partial \nu}{\partial T} \right)_p = \frac{R}{P} \\ P &= CT^{k/(k-1)} \longrightarrow \left( \frac{\partial P}{\partial T} \right)_s = \frac{k}{k-1} CT^{k/(k-1)-1} = \frac{k}{k-1} (PT^{-k/(k-1)}) T^{k/(k-1)-1} = \frac{kP}{T(k-1)} \end{aligned}$$

Substituting,

$$c_p = T \left( \frac{kP}{T(k-1)} \right) \left( \frac{R}{P} \right) = \frac{kR}{k-1} = \frac{1.397(0.297 \text{ kJ/kg}\cdot\text{K})}{1.397-1} = 1.045 \text{ kJ/kg}\cdot\text{K}$$

(b) The  $c_p$  is defined as  $c_p = \left( \frac{\partial h}{\partial T} \right)_p$ . Replacing the differentials by differences,

$$c_p \cong \left( \frac{\Delta h}{\Delta T} \right)_{P=300\text{kPa}} = \frac{h(410 \text{ K}) - h(390 \text{ K})}{(410 - 390)\text{K}} = \frac{(11,932 - 11,347) \text{ kJ/kg}}{(410 - 390)\text{K}} = \mathbf{1.045 \text{ kJ/kg}\cdot\text{K}}$$

(Compare: Table A-2b at 400 K  $\rightarrow c_p = 1.044 \text{ kJ/kg}\cdot\text{K}$ )

**12-96** The temperature change of steam and the average Joule-Thompson coefficient during a throttling process are to be estimated.

**Analysis** The enthalpy of steam at 4.5 MPa and  $T = 300^\circ\text{C}$  is  $h = 2944.2 \text{ kJ/kg}$ . Now consider a throttling process from this state to 2.5 MPa. The temperature of the steam at the end of this throttling process will be

$$\left. \begin{aligned} P &= 2.5 \text{ MPa} \\ h &= 2944.2 \text{ kJ/kg} \end{aligned} \right\} T_2 = 273.72^\circ\text{C}$$

Thus the temperature drop during this throttling process is

$$\Delta T = T_2 - T_1 = 273.72 - 300 = \mathbf{-26.28^\circ\text{C}}$$

The average Joule-Thomson coefficient for this process is determined from

$$\mu = \left( \frac{\partial T}{\partial P} \right)_h \cong \left( \frac{\Delta T}{\Delta P} \right)_{h=2944.2\text{kJ/kg}} = \frac{(273.72 - 300)^\circ\text{C}}{(2.5 - 4.5)\text{MPa}} = \mathbf{13.14^\circ\text{C/MPa}}$$

**12-97** Argon enters a turbine at a specified state and leaves at another specified state. Power output of the turbine and exergy destruction during this process are to be determined using the generalized charts.

**Properties** The gas constant and critical properties of Argon are  $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$ ,  $T_{cr} = 151 \text{ K}$ , and  $P_{cr} = 4.86 \text{ MPa}$  (Table A-1).

**Analysis (a)** The enthalpy and entropy departures of argon at the specified states are determined from the generalized charts to be

$$\left. \begin{aligned} T_{R_1} &= \frac{T_1}{T_{cr}} = \frac{600}{151} = 3.97 \\ P_{R_1} &= \frac{P_1}{P_{cr}} = \frac{7}{4.86} = 1.44 \end{aligned} \right\} Z_{h_1} \cong 0 \text{ and } Z_{s_1} \cong 0$$

Thus argon behaves as an ideal gas at turbine inlet. Also,

$$\left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{cr}} = \frac{280}{151} = 1.85 \\ P_{R_2} &= \frac{P_2}{P_{cr}} = \frac{1}{4.86} = 0.206 \end{aligned} \right\} Z_{h_2} = 0.04 \text{ and } Z_{s_2} = 0.02$$

Thus,

$$h_2 - h_1 = RT_{cr}(Z_{h_1} - Z_{h_2}) + (h_2 - h_1)_{ideal} = (0.2081)(151)(0 - 0.04) + 0.5203(280 - 600) = -167.8 \text{ kJ/kg}$$

The power output of the turbine is to be determined from the energy balance equation,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} = 0 \text{ (steady)} \rightarrow \dot{E}_{in} = \dot{E}_{out} \\ \dot{m}(h_1 + V_1^2/2) &= \dot{m}(h_2 + V_2^2/2) + \dot{Q}_{out} + \dot{W}_{out} \\ \dot{W}_{out} &= -\dot{m} \left[ (h_2 - h_1) + \frac{V_2^2 - V_1^2}{2} \right] - \dot{Q}_{out} \end{aligned}$$

Substituting,

$$\dot{W}_{out} = -(5 \text{ kg/s}) \left( -167.8 + \frac{(150 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right) - 60 \text{ kJ/s} = 747.8 \text{ kW}$$

(b) Under steady conditions, the rate form of the entropy balance for the turbine simplifies to

$$\begin{aligned} \dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} &= \Delta \dot{S}_{system} \overset{\approx 0}{=} 0 \\ \dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{out}}{T_{b,out}} + \dot{S}_{gen} &= 0 \rightarrow \dot{S}_{gen} = \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_0} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition  $X_{destroyed} = T_0 \dot{S}_{gen}$ ,

$$\dot{X}_{destroyed} = T_0 \dot{S}_{gen} = T_0 \left( \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_0} \right)$$

where  $s_2 - s_1 = R(Z_{s_1} - Z_{s_2}) + (s_2 - s_1)_{ideal}$

and  $(s_2 - s_1)_{ideal} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = 0.5203 \ln \frac{280}{600} - 0.2081 \ln \frac{1}{7} = 0.0084 \text{ kJ/kg}\cdot\text{K}$

Thus,  $s_2 - s_1 = R(Z_{s_1} - Z_{s_2}) + (s_2 - s_1)_{ideal} = (0.2081)[0 - (0.02)] + 0.0084 = 0.0042 \text{ kJ/kg}\cdot\text{K}$

Substituting,  $\dot{X}_{destroyed} = (298 \text{ K}) \left( (5 \text{ kg/s})(0.0042 \text{ kJ/kg}\cdot\text{K}) + \frac{60 \text{ kW}}{298 \text{ K}} \right) = \mathbf{66.3 \text{ kW}}$

**12-98 EES** Problem 12-97 is reconsidered. The problem is to be solved assuming steam is the working fluid by using the generalized chart method and EES data for steam. The power output and the exergy destruction rate for these two calculation methods against the turbine exit pressure are to be plotted.

**Analysis** The problem is solved using EES, and the results are tabulated and plotted below.

**12-99** An adiabatic storage tank that is initially evacuated is connected to a supply line that carries nitrogen. A valve is opened, and nitrogen flows into the tank. The final temperature in the tank is to be determined by treating nitrogen as an ideal gas and using the generalized charts, and the results are to be compared to the given actual value.

**Assumptions** 1 Uniform flow conditions exist. 2 Kinetic and potential energies are negligible.

**Analysis** We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy  $h$  and internal energy  $u$ , respectively, the mass and energy balances for this uniform-flow system can be expressed as

$$\text{Mass balance: } m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_i = m_2 \quad (\text{since } m_{\text{out}} = m_{\text{initial}} = 0)$$

$$\text{Energy balance: } E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \rightarrow 0 + m_i h_i = m_2 u_2$$

$$\text{Combining the two balances: } u_2 = h_i$$

(a) From the ideal gas property table of nitrogen, at 225 K we read

$$\bar{u}_2 = \bar{h}_i = \bar{h}_{@225\text{ K}} = 6,537 \text{ kJ/kmol}$$

The temperature that corresponds to this  $\bar{u}_2$  value is

$$T_2 = \mathbf{314.8 \text{ K}} \quad (7.4\% \text{ error})$$

(b) Using the generalized enthalpy departure chart,  $h_i$  is determined to be

$$\left. \begin{aligned} T_{R,i} &= \frac{T_i}{T_{\text{cr}}} = \frac{225}{126.2} = 1.78 \\ P_{R,i} &= \frac{P_i}{P_{\text{cr}}} = \frac{10}{3.39} = 2.95 \end{aligned} \right\} Z_{h,i} = \frac{\bar{h}_{i,\text{ideal}} - \bar{h}_i}{R_u T_{\text{cr}}} = 0.9 \quad (\text{Fig. A-29})$$

Thus,

$$\bar{h}_i = \bar{h}_{i,\text{ideal}} - 0.9 R_u T_{\text{cr}} = 6,537 - (0.9)(8.314)(126.2) = 5,593 \text{ kJ/kmol}$$

and

$$\bar{u}_2 = \bar{h}_i = 5,593 \text{ kJ/kmol}$$

Try  $T_2 = 280 \text{ K}$ . Then at  $P_{R2} = 2.95$  and  $T_{R2} = 2.22$  we read  $Z_2 = 0.98$  and  $(\bar{h}_{2,\text{ideal}} - \bar{h}_2) / R_u T_{\text{cr}} = 0.55$

Thus,

$$\bar{h}_2 = \bar{h}_{2,\text{ideal}} - 0.55 R_u T_{\text{cr}} = 8,141 - (0.55)(8.314)(126.2) = 7,564 \text{ kJ/kmol}$$

$$\bar{u}_2 = \bar{h}_2 - Z R_u T_2 = 7,564 - (0.98)(8.314)(280) = 5,283 \text{ kJ/kmol}$$

Try  $T_2 = 300 \text{ K}$ . Then at  $P_{R2} = 2.95$  and  $T_{R2} = 2.38$  we read  $Z_2 = 1.0$  and  $(\bar{h}_{2,\text{ideal}} - \bar{h}_2) / R_u T_{\text{cr}} = 0.50$

Thus,

$$\bar{h}_2 = \bar{h}_{2,\text{ideal}} - 0.50 R_u T_{\text{cr}} = 8,723 - (0.50)(8.314)(126.2) = 8,198 \text{ kJ/kmol}$$

$$\bar{u}_2 = \bar{h}_2 - Z R_u T_2 = 8,198 - (1.0)(8.314)(300) = 5,704 \text{ kJ/kmol}$$

By linear interpolation,

$$T_2 = \mathbf{294.7 \text{ K}} \quad (0.6\% \text{ error})$$

**12-100** Propane is compressed in a steady-flow device. The entropy change and the specific work required for this compression are to be determined using the departure charts and treating the propane as an ideal gas with temperature variable specific heats.

**Properties** The properties of propane are (Table A-1, A-2a)

$$M = 44.097 \text{ kg/kmol}, R = 0.1885 \text{ kJ/kg} \cdot \text{K}, T_{\text{cr}} = 370 \text{ K}, P_{\text{cr}} = 4.26 \text{ MPa}, c_p = 1.6794 \text{ kJ/kg} \cdot \text{K}$$

**Analysis** (a) Using empirical correlation for the  $c_p$  of propane as given in Table A-2c gives

$$\begin{aligned} \bar{w}_{\text{in}} &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \int_1^2 c_p dT = \int_1^2 (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= -4.04(773 - 373) + \frac{0.3048}{2}(773^2 - 373^2) - \frac{15.72 \times 10^{-5}}{3}(773^3 - 373^3) + \frac{31.74 \times 10^{-9}}{4}(773^4 - 373^4) \\ &= 49,440 \text{ kJ/kmol} \end{aligned}$$

The work input per unit mass is

$$w_{\text{in}} = \frac{\bar{w}_{\text{in}}}{M} = \frac{49,440 \text{ kJ/kmol}}{44.097 \text{ kg/kmol}} = \mathbf{1121 \text{ kJ/kg}}$$

Similarly, the entropy change is given by

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left( \frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \\ &= -4.04 \ln \frac{773}{373} + 0.3048(773 - 373) - \frac{15.72 \times 10^{-5}}{2}(773^2 - 373^2) + \frac{31.74 \times 10^{-9}}{3}(773^3 - 373^3) \\ &\quad - (8.314) \ln \frac{4000}{500} \\ &= 69.995 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

The entropy change per unit mass is

$$(s_2 - s_1)_{\text{ideal}} = \frac{(\bar{s}_2 - \bar{s}_1)_{\text{ideal}}}{M} = \frac{69.995 \text{ kJ/kmol} \cdot \text{K}}{44.097 \text{ kg/kmol}} = \mathbf{1.587 \text{ kJ/kg} \cdot \text{K}}$$

(b) The enthalpy and entropy departures of propane at the specified states are determined from the generalized charts to be (Fig. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{0.5}{4.26} = 0.117 \end{aligned} \right\} \begin{aligned} Z_{h1} &= 0.124 \\ Z_{s1} &= 0.0837 \end{aligned} \quad \left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{773}{370} = 2.089 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \begin{aligned} Z_{h2} &= 0.233 \\ Z_{s2} &= 0.105 \end{aligned}$$

The work input is determined from

$$\begin{aligned} w_{\text{in}} &= h_2 - h_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= 1121 - (0.1885)(370)(0.233 - 0.124) = \mathbf{1113 \text{ kJ/kg}} \end{aligned}$$

and the entropy change is determined to be

$$s_2 - s_1 = (s_2 - s_1)_{\text{ideal}} - R(Z_{s2} - Z_{s1})$$

$$= 1.587 - (0.1885)(0.105 - 0.0837) = \mathbf{1.583 \text{ kJ/kg} \cdot \text{K}}$$

**Discussion** Let us see what happens when constant specific heats for propane at the room temperature are used when calculating enthalpy and entropy changes under ideal gas assumption. The entropy and enthalpy changes are determined from

$$(h_2 - h_1)_{\text{ideal}} = c_p (T_2 - T_1) = (1.6794 \text{ kJ/kg} \cdot \text{K})(500 - 100)\text{K} = 671.8 \text{ kJ/kg}$$

$$(s_2 - s_1)_{\text{ideal}} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$$

$$= (1.6794) \ln \frac{773}{373} - (0.1885) \ln \frac{4000}{500} = 0.8318 \text{ kJ/kg} \cdot \text{K}$$

With departure factors,

$$w_{\text{in}} = h_2 - h_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1})$$

$$= 671.8 - (0.1885)(370)(0.233 - 0.124) = 664.2 \text{ kJ/kg}$$

$$s_2 - s_1 = (s_2 - s_1)_{\text{ideal}} - R(Z_{s2} - Z_{s1})$$

$$= 0.8318 - (0.1885)(0.105 - 0.0837) = \mathbf{0.8278 \text{ kJ/kg} \cdot \text{K}}$$

These are not any close to the results obtained using variable specific heats. This shows that using constant specific heats may yield unacceptable results.

**12-101** Propane is compressed in a steady-flow device. The second-law efficiency of the compression process is to be determined.

**Properties** The properties of propane are (Table A-1, A-2a)

$$M = 44.097 \text{ kg/kmol}, R = 0.1885 \text{ kJ/kg} \cdot \text{K}, T_{\text{cr}} = 370 \text{ K}, P_{\text{cr}} = 4.26 \text{ MPa}, c_p = 1.6794 \text{ kJ/kg} \cdot \text{K}$$

**Analysis** Using the variable specific heat results of the previous problem, the actual and reversible works are

$$\begin{aligned} w_{\text{in}} &= h_2 - h_1 = 1113 \text{ kJ/kg} \\ w_{\text{rev,in}} &= h_2 - h_1 - T_0 (s_2 - s_1) = 1113 \text{ kJ/kg} - (298 \text{ K})(1.583 \text{ kJ/kg} \cdot \text{K}) = 641.3 \text{ kJ/kg} \end{aligned}$$

The second-law efficiency is then

$$\eta_{\text{II}} = \frac{w_{\text{rev,in}}}{w_{\text{rev,in}}} = \frac{641.3}{1113} = \mathbf{0.576}$$

**12-102E** Methane is to be adiabatically and reversibly compressed in a steady-flow device. The specific work required for this compression is to be determined using the departure charts and treating the methane as an ideal gas with temperature variable specific heats.

**Properties** The properties of methane are (Table A-1E)

$$M = 16.043 \text{ lbm/lbmol}, R = 0.1238 \text{ Btu/lbm} \cdot \text{R}, T_{\text{cr}} = 343.9 \text{ R}, P_{\text{cr}} = 673 \text{ psia}$$

**Analysis** The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. When the expression of Table A-2Ec is substituted for  $c_p$  and the integration performed, we obtain

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left( \frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \end{aligned}$$

Substituting,

$$\begin{aligned} 0 &= 4.75 \ln \frac{T_2}{560} + 0.006666(T_2 - 560) + \frac{0.09352 \times 10^{-5}}{2}(T_2^2 - 560^2) \\ &\quad - \frac{0.4510 \times 10^{-9}}{3}(T_2^3 - 560^3) - (1.9858) \ln \frac{500}{50} \end{aligned}$$

Solving this equation by EES or an iterative solution gives

$$T_2 = 892 \text{ R}$$

When an energy balance is applied to the compressor, it becomes

$$\begin{aligned} \bar{w}_{\text{in}} &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \int_1^2 c_p dT = \int_1^2 (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 4.75(892 - 560) + \frac{0.006666}{2}(892^2 - 560^2) + \frac{0.09352 \times 10^{-5}}{3}(892^3 - 560^3) \\ &\quad - \frac{0.4510 \times 10^{-9}}{4}(892^4 - 560^4) \\ &= 3290 \text{ Btu/lbmol} \end{aligned}$$

The work input per unit mass basis is

$$w_{\text{in}} = \frac{\bar{w}_{\text{in}}}{M} = \frac{3290 \text{ Btu/lbmol}}{16.043 \text{ lbm/lbmol}} = \mathbf{205.1 \text{ Btu/lbm}}$$

The enthalpy departures of propane at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{560}{343.9} = 1.628 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{50}{673} = 0.0743 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.0332$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{892}{343.9} = 2.594 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{500}{673} = 0.743 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.0990$$

The work input is determined to be

$$\begin{aligned} w_{in} &= h_2 - h_1 = (h_2 - h_1)_{ideal} - RT_{cr}(Z_{h2} - Z_{h1}) \\ &= 205.1 \text{ Btu/lbm} - (0.1238 \text{ Btu/lbm} \cdot \text{R})(343.9 \text{ R})(0.0990 - 0.0332) \\ &= \mathbf{202.3 \text{ Btu/lbm}} \end{aligned}$$

**12-103** The volume expansivity of water is given. The change in volume of water when it is heated at constant pressure is to be determined.

**Properties** The volume expansivity of water is given to be  $0.207 \times 10^{-6} \text{ K}^{-1}$  at  $20^\circ\text{C}$ .

**Analysis** We take  $\nu = \nu(P, T)$ . Its total differential is

$$d\nu = \left( \frac{\partial \nu}{\partial T} \right)_P dT + \left( \frac{\partial \nu}{\partial P} \right)_T dP$$

which, for a constant pressure process, reduces to

$$d\nu = \left( \frac{\partial \nu}{\partial T} \right)_P dT$$

Dividing by  $\nu$  and using the definition of  $\beta$ ,

$$\frac{d\nu}{\nu} = \frac{1}{\nu} \left( \frac{\partial \nu}{\partial T} \right)_P dT = \beta dT$$

Taking  $\beta$  to be a constant, integration from 1 to 2 yields

$$\ln \frac{\nu_2}{\nu_1} = \beta(T_2 - T_1)$$

or

$$\frac{\nu_2}{\nu_1} = \exp[\beta(T_2 - T_1)]$$

Substituting the given values and noting that for a fixed mass  $\nu_2/\nu_1 = v_2/v_1$ ,

$$\begin{aligned} \nu_2 &= \nu_1 \exp[\beta(T_2 - T_1)] = (1 \text{ m}^3) \exp[(0.207 \times 10^{-6} \text{ K}^{-1})(30 - 10)^\circ\text{C}] \\ &= 1.00000414 \text{ m}^3 \end{aligned}$$

Therefore,

$$\Delta \nu = \nu_2 - \nu_1 = 1.00000414 - 1 = 0.00000414 \text{ m}^3 = \mathbf{4.14 \text{ cm}^3}$$

**12-104** It is to be shown that the position of the Joule-Thompson coefficient inversion curve on the  $T$ - $P$  plane is given by  $(\partial Z/\partial T)_P = 0$ .

**Analysis** The inversion curve is the locus of the points at which the Joule-Thompson coefficient  $\mu$  is zero,

$$\mu = \frac{1}{c_p} \left( T \left( \frac{\partial \nu}{\partial T} \right)_P - \nu \right) = 0$$

which can also be written as

$$T \left( \frac{\partial \nu}{\partial T} \right)_P - \frac{ZRT}{P} = 0 \quad (a)$$

since it is given that

$$\nu = \frac{ZRT}{P} \quad (b)$$

Taking the derivative of (b) with respect to  $T$  holding  $P$  constant gives

$$\left( \frac{\partial \nu}{\partial T} \right)_P = \left( \frac{\partial (ZRT/P)}{\partial T} \right)_P = \frac{R}{P} \left( T \left( \frac{\partial Z}{\partial T} \right)_P + Z \right)$$

Substituting in (a),

$$\begin{aligned} \frac{TR}{P} \left( T \left( \frac{\partial Z}{\partial T} \right)_P + Z \right) - \frac{ZRT}{P} &= 0 \\ T \left( \frac{\partial Z}{\partial T} \right)_P + Z - Z &= 0 \\ \left( \frac{\partial Z}{\partial T} \right)_P &= 0 \end{aligned}$$

which is the desired relation.

**12-105** It is to be shown that for an isentropic expansion or compression process  $P\nu^k = \text{constant}$ . It is also to be shown that the isentropic expansion exponent  $k$  reduces to the specific heat ratio  $c_p/c_v$  for an ideal gas.

**Analysis** We note that  $ds = 0$  for an isentropic process. Taking  $s = s(P, \nu)$ , the total differential  $ds$  can be expressed as

$$ds = \left( \frac{\partial s}{\partial P} \right)_{\nu} dP + \left( \frac{\partial s}{\partial \nu} \right)_P d\nu = 0 \quad (a)$$

We now substitute the Maxwell relations below into (a)

$$\left( \frac{\partial s}{\partial P} \right)_{\nu} = - \left( \frac{\partial \nu}{\partial T} \right)_s \quad \text{and} \quad \left( \frac{\partial s}{\partial \nu} \right)_P = \left( \frac{\partial P}{\partial T} \right)_s$$

to get

$$- \left( \frac{\partial \nu}{\partial T} \right)_s dP + \left( \frac{\partial P}{\partial T} \right)_s d\nu = 0$$

Rearranging,

$$dP - \left( \frac{\partial T}{\partial \nu} \right)_s \left( \frac{\partial P}{\partial T} \right)_s d\nu = 0 \longrightarrow dP - \left( \frac{\partial P}{\partial \nu} \right)_s d\nu = 0$$

$$\text{Dividing by } P, \quad \frac{dP}{P} - \frac{1}{P} \left( \frac{\partial P}{\partial \nu} \right)_s d\nu = 0 \quad (b)$$

We now define isentropic expansion exponent  $k$  as

$$k = - \frac{\nu}{P} \left( \frac{\partial P}{\partial \nu} \right)_s$$

Substituting in (b),

$$\frac{dP}{P} + k \frac{d\nu}{\nu} = 0$$

Taking  $k$  to be a constant and integrating,

$$\ln P + k \ln \nu = \text{constant} \longrightarrow \ln P\nu^k = \text{constant}$$

Thus,

$$P\nu^k = \text{constant}$$

To show that  $k = c_p/c_v$  for an ideal gas, we write the cyclic relations for the following two groups of variables:

$$(s, T, \nu) \longrightarrow \left( \frac{\partial s}{\partial T} \right)_{\nu} \left( \frac{\partial \nu}{\partial s} \right)_T \left( \frac{\partial T}{\partial \nu} \right)_s = -1 \longrightarrow \frac{c_v}{T} \left( \frac{\partial \nu}{\partial s} \right)_T \left( \frac{\partial T}{\partial \nu} \right)_s = -1 \quad (c)$$

$$(s, T, P) \longrightarrow \left( \frac{\partial s}{\partial T} \right)_P \left( \frac{\partial P}{\partial s} \right)_T \left( \frac{\partial T}{\partial P} \right)_s = -1 \longrightarrow \frac{c_p}{T} \left( \frac{\partial P}{\partial s} \right)_T \left( \frac{\partial T}{\partial P} \right)_s = -1 \quad (d)$$

where we used the relations

$$c_v = T \left( \frac{\partial s}{\partial T} \right)_{\nu} \quad \text{and} \quad c_p = T \left( \frac{\partial s}{\partial T} \right)_P$$

Setting Eqs. (c) and (d) equal to each other,

$$\frac{c_p}{T} \left( \frac{\partial P}{\partial s} \right)_T \left( \frac{\partial T}{\partial P} \right)_s = \frac{c_v}{T} \left( \frac{\partial v}{\partial s} \right)_T \left( \frac{\partial T}{\partial v} \right)_s$$

or,

$$\frac{c_p}{c_v} = \left( \frac{\partial s}{\partial P} \right)_T \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial v}{\partial s} \right)_T \left( \frac{\partial T}{\partial v} \right)_s = \left( \frac{\partial s}{\partial P} \frac{\partial v}{\partial s} \right)_T \left( \frac{\partial P}{\partial T} \frac{\partial T}{\partial v} \right)_s = \left( \frac{\partial v}{\partial P} \right)_T \left( \frac{\partial P}{\partial v} \right)_s$$

but

$$\left( \frac{\partial v}{\partial P} \right)_T = \left( \frac{\partial (RT/P)}{\partial P} \right)_T = -\frac{v}{P}$$

Substituting,

$$\frac{c_p}{c_v} = -\frac{v}{P} \left( \frac{\partial P}{\partial v} \right)_s = k$$

which is the desired relation.

**12-106 EES** The work done by the refrigerant 134a as it undergoes an isothermal process in a closed system is to be determined using the tabular (EES) data and the generalized charts.

**Analysis** The solution using EES built-in property data is as follows:

$$\left. \begin{aligned} T_1 &= 60^\circ\text{C} \\ P_1 &= 3 \text{ MPa} \end{aligned} \right\} \begin{aligned} u_1 &= 135.65 \text{ kJ/kg} \\ s_1 &= 0.4828 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} T_2 &= 60^\circ\text{C} \\ P_2 &= 0.1 \text{ MPa} \end{aligned} \right\} \begin{aligned} u_2 &= 280.35 \text{ kJ/kg} \\ s_2 &= 1.2035 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\Delta s_{\text{EES}} = s_2 - s_1 = 1.2035 - 0.4828 = 0.7207 \text{ kJ/kg}\cdot\text{K}$$

$$q_{\text{EES}} = T_1 \Delta s_{\text{EES}} = (60 + 273.15 \text{ K})(0.7207 \text{ kJ/kg}\cdot\text{K}) = 240.11 \text{ kJ/kg}$$

$$w_{\text{EES}} = q_{\text{EES}} - (u_2 - u_1) = 240.1 - (280.35 - 135.65) = \mathbf{95.40 \text{ kJ/kg}}$$

For the generalized chart solution we first determine the following factors using EES as

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{333.15}{374.2} = 0.8903 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{3}{4.059} = 0.7391 \end{aligned} \right\} \longrightarrow Z_1 = 0.1292, Z_{h1} = 4.475 \text{ and } Z_{s1} = 4.383$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{333.15}{374.2} = 0.8903 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{0.1}{4.059} = 0.02464 \end{aligned} \right\} \longrightarrow Z_2 = 0.988, Z_{h2} = 0.03091 \text{ and } Z_{s2} = 0.02281$$

Then,

$$\Delta h_1 = Z_{h1} R T_{cr} = (4.475)(0.08148 \text{ kJ/kg}\cdot\text{K})(374.2 \text{ K}) = 136.43 \text{ kJ/kg}$$

$$\Delta s_1 = Z_{s1} R = (4.383)(0.08148 \text{ kJ/kg}\cdot\text{K}) = 0.3572 \text{ kJ/kg}\cdot\text{K}$$

$$\Delta h_2 = Z_{h2} R T_{cr} = (0.03091)(0.08148 \text{ kJ/kg}\cdot\text{K})(374.2 \text{ K}) = 0.94 \text{ kJ/kg}$$

$$\Delta s_2 = Z_{s2} R = (0.02281)(0.08148 \text{ kJ/kg}\cdot\text{K}) = 0.001858 \text{ kJ/kg}\cdot\text{K}$$

$$\Delta s_{\text{ideal}} = R \ln \frac{P_2}{P_1} = (0.08148 \text{ kJ/kg}\cdot\text{K}) \ln \left( \frac{0.1}{3} \right) = 0.2771 \text{ kJ/kg}\cdot\text{K}$$

$$\Delta s_{\text{chart}} = \Delta s_{\text{ideal}} - (\Delta s_2 - \Delta s_1) = 0.2771 - (0.001858 - 0.3572) = 0.6324 \text{ kJ/kg}\cdot\text{K}$$

$$q_{\text{chart}} = T_1 \Delta s_{\text{chart}} = (60 + 273.15 \text{ K})(0.6324 \text{ kJ/kg}\cdot\text{K}) = 210.70 \text{ kJ/kg}$$

$$\begin{aligned} \Delta u_{\text{chart}} &= \Delta h_{\text{ideal}} - (\Delta h_2 - \Delta h_1) - (Z_2 R T_2 - Z_1 R T_1) \\ &= 0 - (0.94 - 136.43) - [(0.988)(0.08148)(333) - (0.1292)(0.08148)(333)] = 112.17 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{chart}} = q_{\text{chart}} - \Delta u_{\text{chart}} = 210.70 - 112.17 = \mathbf{98.53 \text{ kJ/kg}}$$

The copy of the EES solution of this problem is given next.

**12-107** The heat transfer, work, and entropy changes of methane during a process in a piston-cylinder device are to be determined assuming ideal gas behavior, using generalized charts, and real fluid (EES) data.

**Analysis** The ideal gas solution: (Properties are obtained from EES)

State 1:

$$\begin{aligned} T_1 &= 100^\circ\text{C} \longrightarrow h_1 = -4492 \text{ kJ/kg} \\ T_1 &= 100^\circ\text{C}, P_1 = 4 \text{ MPa} \longrightarrow s_1 = 10.22 \text{ kJ/kg}\cdot\text{K} \\ u_1 &= h_1 - RT_1 = (-4492) - (0.5182)(100 + 273.15) = -4685 \text{ kJ/kg} \\ \nu_1 &= R \frac{T_1}{P_1} = (0.5182 \text{ kJ/kg}\cdot\text{K}) \left( \frac{100 + 273.15 \text{ K}}{4000 \text{ kPa}} \right) = 0.04834 \text{ m}^3/\text{kg} \end{aligned}$$

State 2:

$$\begin{aligned} T_2 &= 350^\circ\text{C} \longrightarrow h_2 = -3770 \text{ kJ/kg} \\ T_2 &= 350^\circ\text{C}, P_2 = 4 \text{ MPa} \longrightarrow s_2 = 11.68 \text{ kJ/kg}\cdot\text{K} \\ u_2 &= h_2 - RT_2 = (-3770) - (0.5182)(350 + 273.15) = -4093 \text{ kJ/kg} \\ \nu_2 &= R \frac{T_2}{P_2} = (0.5182 \text{ kJ/kg}\cdot\text{K}) \left( \frac{350 + 273.15 \text{ K}}{4000 \text{ kPa}} \right) = 0.08073 \text{ m}^3/\text{kg} \\ w_{\text{ideal}} &= P(\nu_2 - \nu_1) = (4000 \text{ kPa})(0.08073 - 0.04834) \text{ m}^3/\text{kg} = \mathbf{129.56 \text{ kJ/kg}} \\ q_{\text{ideal}} &= w_{\text{ideal}} + (u_2 - u_1) = 129.56 + [(-4093) - (-4685)] = \mathbf{721.70 \text{ kJ/kg}} \\ \Delta s_{\text{ideal}} &= s_2 - s_1 = 11.68 - 10.22 = \mathbf{1.46 \text{ kJ/kg}} \end{aligned}$$

For the generalized chart solution we first determine the following factors using EES as

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{304.2} = 1.227 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{4}{7.39} = 0.5413 \end{aligned} \right\} \longrightarrow Z_1 = 0.9023, Z_{h1} = 0.4318 \text{ and } Z_{s1} = 0.2555$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{623}{304.2} = 2.048 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{4}{7.39} = 0.5413 \end{aligned} \right\} \longrightarrow Z_2 = 0.995, Z_{h2} = 0.1435 \text{ and } Z_{s2} = 0.06446$$

State 1:

$$\begin{aligned} \Delta h_1 &= Z_{h1} RT_{\text{cr}} = (0.4318)(0.5182 \text{ kJ/kg}\cdot\text{K})(304.2 \text{ K}) = 68.07 \text{ kJ/kg} \\ h_1 &= h_{1,\text{ideal}} - \Delta h_1 = (-4492) - 68.07 = -4560 \text{ kJ/kg} \\ u_1 &= h_1 - Z_1 RT_1 = (-4560) - (0.9023)(0.5182)(373.15) = -4734 \text{ kJ/kg} \\ \nu_1 &= Z_1 R \frac{T_1}{P_1} = (0.9023)(0.5182) \frac{373.15}{4000} = 0.04362 \text{ m}^3/\text{kg} \\ \Delta s_1 &= Z_{s1} R = (0.2555)(0.5182 \text{ kJ/kg}\cdot\text{K}) = 0.1324 \text{ kJ/kg}\cdot\text{K} \\ s_1 &= s_{1,\text{ideal}} - \Delta s_1 = 10.22 - 0.1324 = 10.09 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

State 2:

$$\Delta h_2 = Z_{h_2} R T_{cr} = (0.1435)(0.5182 \text{ kJ/kg}\cdot\text{K})(304.2 \text{ K}) = 22.62 \text{ kJ/kg}$$

$$h_2 = h_{2,\text{ideal}} - \Delta h_2 = (-3770) - 22.62 = -3793 \text{ kJ/kg}$$

$$u_2 = h_2 - Z_2 R T_2 = (-3793) - (0.995)(0.5182)(623.15) = -4114 \text{ kJ/kg}$$

$$\nu_2 = Z_2 R \frac{T_2}{P_2} = (0.995)(0.5182) \frac{623.15}{4000} = 0.08033 \text{ m}^3/\text{kg}$$

$$\Delta s_2 = Z_{s_2} R = (0.06446)(0.5182 \text{ kJ/kg}\cdot\text{K}) = 0.03341 \text{ kJ/kg}\cdot\text{K}$$

$$s_2 = s_{2,\text{ideal}} - \Delta s_2 = 11.68 - 0.03341 = 11.65 \text{ kJ/kg}\cdot\text{K}$$

Then,

$$w_{\text{chart}} = P(\nu_2 - \nu_1) = (4000 \text{ kPa})(0.08033 - 0.04362) \text{ m}^3/\text{kg} = \mathbf{146.84 \text{ kJ/kg}}$$

$$q_{\text{chart}} = w_{\text{chart}} + (u_2 - u_1) = 146.84 + [(-4114) - (-4734)] = \mathbf{766.84 \text{ kJ/kg}}$$

$$\Delta s_{\text{chart}} = s_2 - s_1 = 11.65 - 10.09 = \mathbf{1.56 \text{ kJ/kg}}$$

The solution using EES built-in property data is as follows:

$$\left. \begin{array}{l} T_1 = 100^\circ\text{C} \\ P_1 = 4 \text{ MPa} \end{array} \right\} \begin{array}{l} \nu_1 = 0.04717 \text{ m}^3/\text{kg} \\ u_1 = -39.82 \text{ kJ/kg} \\ s_1 = -1.439 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} T_2 = 350^\circ\text{C} \\ P_2 = 4 \text{ MPa} \end{array} \right\} \begin{array}{l} \nu_2 = 0.08141 \text{ m}^3/\text{kg} \\ u_2 = 564.52 \text{ kJ/kg} \\ s_2 = 0.06329 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$w_{\text{EES}} = P(\nu_2 - \nu_1) = (4000 \text{ kPa})(0.08141 - 0.04717) \text{ m}^3/\text{kg} = \mathbf{136.96 \text{ kJ/kg}}$$

$$q_{\text{EES}} = w_{\text{EES}} + (u_2 - u_1) = 136.97 + [564.52 - (-39.82)] = \mathbf{741.31 \text{ kJ/kg}}$$

$$\Delta s_{\text{EES}} = s_2 - s_1 = 0.06329 - (-1.439) = \mathbf{1.50 \text{ kJ/kg}}$$

## Fundamentals of Engineering (FE) Exam Problems

**12-108** A substance whose Joule-Thomson coefficient is negative is throttled to a lower pressure. During this process, (select the correct statement)

- (a) the temperature of the substance will increase.
- (b) the temperature of the substance will decrease.
- (c) the entropy of the substance will remain constant.
- (d) the entropy of the substance will decrease.
- (e) the enthalpy of the substance will decrease.

*Answer* (a) the temperature of the substance will increase.

**12-109** Consider the liquid-vapor saturation curve of a pure substance on the  $P$ - $T$  diagram. The magnitude of the slope of the tangent line to this curve at a temperature  $T$  (in Kelvin) is

- (a) proportional to the enthalpy of vaporization  $h_{fg}$  at that temperature,
- (b) proportional to the temperature  $T$ ,
- (c) proportional to the square of the temperature  $T$ ,
- (d) proportional to the volume change  $v_{fg}$  at that temperature,
- (e) inversely proportional to the entropy change  $s_{fg}$  at that temperature,

*Answer* (a) proportional to the enthalpy of vaporization  $h_{fg}$  at that temperature,

**12-110** Based on the generalized charts, the error involved in the enthalpy of  $\text{CO}_2$  at 350 K and 8 MPa if it is assumed to be an ideal gas is

- (a) 0
- (b) 20%
- (c) 33%
- (d) 26%
- (e) 65%

*Answer* (c) 33%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T=350 "K"
P=8000 "kPa"
Pcr=P_CRIT(CarbonDioxide)
Tcr=T_CRIT(CarbonDioxide)
Tr=T/Tcr
Pr=P/Pcr
hR=ENTHDEP(Tr, Pr)
h_ideal=11351/Molarmass(CO2) "Table A-20 of the text"
h_chart=h_ideal-R*Tcr*hR
R=0.1889
Error=(h_chart-h_ideal)/h_chart*Convert(, %)
```

**12-111** Based on data from the refrigerant-134a tables, the Joule-Thompson coefficient of refrigerant-134a at 0.8 MPa and 100°C is approximately

- (a) 0                      (b) -5°C/MPa                      (c) 11°C/MPa                      (d) 8°C/MPa                      (e) 26°C/MPa

*Answer* (c) 11°C/MPa

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=100 "C"
P1=800 "kPa"
h1=ENTHALPY(R134a,T=T1,P=P1)
Tlow=TEMPERATURE(R134a,h=h1,P=P1+100)
Thigh=TEMPERATURE(R134a,h=h1,P=P1-100)
JT=(Tlow-Thigh)/200
```

**12-112** For a gas whose equation of state is  $P(\nu - b) = RT$ , the specific heat difference  $c_p - c_\nu$  is equal to

- (a)  $R$                       (b)  $R - b$                       (c)  $R + b$                       (d) 0                      (e)  $R(1 + \nu/b)$

*Answer* (a)  $R$

**Solution** The general relation for the specific heat difference  $c_p - c_\nu$  is

$$c_p - c_\nu = -T \left( \frac{\partial \nu}{\partial T} \right)_P^2 \left( \frac{\partial P}{\partial \nu} \right)_T$$

For the given gas,  $P(\nu - b) = RT$ . Then,

$$\nu = \frac{RT}{P} + b \longrightarrow \left( \frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

$$P = \frac{RT}{\nu - b} \longrightarrow \left( \frac{\partial P}{\partial \nu} \right)_T = -\frac{RT}{(\nu - b)^2} = -\frac{P}{\nu - b}$$

Substituting,

$$c_p - c_\nu = -T \left( \frac{R}{P} \right)^2 \left( -\frac{P}{\nu - b} \right) = \frac{TR^2}{P(\nu - b)} = R$$

## 12-113 ... 12-115 Design and Essay Problems

## Chapter 13

# GAS MIXTURES

### Composition of Gas Mixtures

**13-1C** It is the average or the equivalent gas constant of the gas mixture. No.

**13-2C** No. We can do this only when each gas has the same mole fraction.

**13-3C** It is the average or the equivalent molar mass of the gas mixture. No.

**13-4C** The mass fractions will be identical, but the mole fractions will not.

**13-5C** Yes.

**13-6C** The ratio of the mass of a component to the mass of the mixture is called the mass fraction ( $mf$ ), and the ratio of the mole number of a component to the mole number of the mixture is called the mole fraction ( $y$ ).

**13-7C** From the definition of mass fraction,

$$mf_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \left( \frac{M_i}{M_m} \right)$$

**13-8C** Yes, because both  $\text{CO}_2$  and  $\text{N}_2\text{O}$  has the same molar mass,  $M = 44 \text{ kg/kmol}$ .

**13-9** A mixture consists of two gases. Relations for mole fractions when mass fractions are known are to be obtained .

**Analysis** The mass fractions of  $A$  and  $B$  are expressed as

$$\text{mf}_A = \frac{m_A}{m_m} = \frac{N_A M_A}{N_m M_m} = y_A \frac{M_A}{M_m} \quad \text{and} \quad \text{mf}_B = y_B \frac{M_B}{M_m}$$

Where  $m$  is mass,  $M$  is the molar mass,  $N$  is the number of moles, and  $y$  is the mole fraction. The apparent molar mass of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{N_A M_A + N_B M_B}{N_m} = y_A M_A + y_B M_B$$

Combining the two equation above and noting that  $y_A + y_B = 1$  gives the following convenient relations for converting mass fractions to mole fractions,

$$y_A = \frac{M_B}{M_A(1/\text{mf}_A - 1) + M_B} \quad \text{and} \quad y_B = 1 - y_A$$

which are the desired relations.

**13-10** The definitions for the mass fraction, weight, and the weight fractions are

$$\begin{aligned} (\text{mf})_i &= \frac{m_i}{m_{\text{total}}} \\ W &= mg \\ (\text{wf})_i &= \frac{W_i}{W_{\text{total}}} \end{aligned}$$

Since the total system consists of one mass unit, the mass of the  $i$ th component in this mixture is  $x_i$ . The weight of this one component is then

$$W_i = g(\text{mf})_i$$

Hence, the weight fraction for this one component is

$$(\text{wf})_i = \frac{g(\text{mf})_i}{\sum g(\text{mf})_i} = (\text{mf})_i$$

**13-11** The moles of components of a gas mixture are given. The mole fractions and the apparent molecular weight are to be determined.

**Properties** The molar masses of He, O<sub>2</sub>, N<sub>2</sub>, and H<sub>2</sub>O are 4.0, 32.0, 28.0 and 18.0 lbm/lbmol, respectively (Table A-1).

**Analysis** The total mole number of the mixture is

$$N_m = N_{\text{He}} + N_{\text{O}_2} + N_{\text{H}_2\text{O}} + N_{\text{N}_2} = 1 + 2 + 0.1 + 1.5 = 4.6 \text{ lbmol}$$

and the mole fractions are

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_m} = \frac{1 \text{ lbmol}}{4.6 \text{ lbmol}} = \mathbf{0.217}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{2 \text{ lbmol}}{4.6 \text{ lbmol}} = \mathbf{0.435}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{0.1 \text{ lbmol}}{4.6 \text{ lbmol}} = \mathbf{0.0217}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{1.5 \text{ lbmol}}{4.6 \text{ lbmol}} = \mathbf{0.326}$$

|                                                                                                |
|------------------------------------------------------------------------------------------------|
| 1 lbmol He<br>2 lbmol O <sub>2</sub><br>0.1 lbmol H <sub>2</sub> O<br>1.5 lbmol N <sub>2</sub> |
|------------------------------------------------------------------------------------------------|

The total mass of the mixture is

$$\begin{aligned} m_m &= m_{\text{He}} + m_{\text{O}_2} + m_{\text{H}_2\text{O}} + m_{\text{N}_2} \\ &= N_{\text{He}} M_{\text{He}} + N_{\text{O}_2} M_{\text{O}_2} + N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} + N_{\text{N}_2} M_{\text{N}_2} \\ &= (1 \text{ lbm})(4 \text{ lbm/lbmol}) + (2 \text{ lbm})(32 \text{ lbm/lbmol}) + (0.1 \text{ lbm})(18 \text{ lbm/lbmol}) + (1.5 \text{ lbm})(28 \text{ lbm/lbmol}) \\ &= 111.8 \text{ kg} \end{aligned}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{111.8 \text{ lbm}}{4.6 \text{ lbmol}} = \mathbf{24.3 \text{ lbm/lbmol}}$$

**13-12** The masses of the constituents of a gas mixture are given. The mass fractions, the mole fractions, the average molar mass, and gas constant are to be determined.

**Properties** The molar masses of  $O_2$ ,  $N_2$ , and  $CO_2$  are 32.0, 28.0 and 44.0 kg/kmol, respectively (Table A-1)

**Analysis** (a) The total mass of the mixture is

$$m_m = m_{O_2} + m_{N_2} + m_{CO_2} = 5 \text{ kg} + 8 \text{ kg} + 10 \text{ kg} = 23 \text{ kg}$$

Then the mass fraction of each component becomes

$$\text{mf}_{O_2} = \frac{m_{O_2}}{m_m} = \frac{5 \text{ kg}}{23 \text{ kg}} = \mathbf{0.217}$$

$$\text{mf}_{N_2} = \frac{m_{N_2}}{m_m} = \frac{8 \text{ kg}}{23 \text{ kg}} = \mathbf{0.348}$$

$$\text{mf}_{CO_2} = \frac{m_{CO_2}}{m_m} = \frac{10 \text{ kg}}{23 \text{ kg}} = \mathbf{0.435}$$

|                                          |
|------------------------------------------|
| 5 kg $O_2$<br>8 kg $N_2$<br>10 kg $CO_2$ |
|------------------------------------------|

(b) To find the mole fractions, we need to determine the mole numbers of each component first,

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{5 \text{ kg}}{32 \text{ kg/kmol}} = 0.156 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{8 \text{ kg}}{28 \text{ kg/kmol}} = 0.286 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{10 \text{ kg}}{44 \text{ kg/kmol}} = 0.227 \text{ kmol}$$

Thus,

$$N_m = N_{O_2} + N_{N_2} + N_{CO_2} = 0.156 \text{ kmol} + 0.286 \text{ kmol} + 0.227 \text{ kmol} = 0.669 \text{ kmol}$$

and

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.156 \text{ kmol}}{0.669 \text{ kmol}} = \mathbf{0.233}$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.286 \text{ kmol}}{0.669 \text{ kmol}} = \mathbf{0.428}$$

$$y_{CO_2} = \frac{N_{CO_2}}{N_m} = \frac{0.227 \text{ kmol}}{0.669 \text{ kmol}} = \mathbf{0.339}$$

(c) The average molar mass and gas constant of the mixture are determined from their definitions:

$$M_m = \frac{m_m}{N_m} = \frac{23 \text{ kg}}{0.669 \text{ kmol}} = \mathbf{34.4 \text{ kg/kmol}}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{34.4 \text{ kg/kmol}} = \mathbf{0.242 \text{ kJ/kg} \cdot \text{K}}$$

**13-13** The mass fractions of the constituents of a gas mixture are given. The mole fractions of the gas and gas constant are to be determined.

**Properties** The molar masses of  $\text{CH}_4$  and  $\text{CO}_2$  are 16.0 and 44.0 kg/kmol, respectively (Table A-1)

**Analysis** For convenience, consider 100 kg of the mixture. Then the number of moles of each component and the total number of moles are

$$m_{\text{CH}_4} = 75 \text{ kg} \longrightarrow N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ kg}}{16 \text{ kg/kmol}} = 4.688 \text{ kmol}$$

$$m_{\text{CO}_2} = 25 \text{ kg} \longrightarrow N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.568 \text{ kmol}$$

$$N_m = N_{\text{CH}_4} + N_{\text{CO}_2} = 4.688 \text{ kmol} + 0.568 \text{ kmol} = 5.256 \text{ kmol}$$

|                   |
|-------------------|
| mass              |
| 75% $\text{CH}_4$ |
| 25% $\text{CO}_2$ |

Then the mole fraction of each component becomes

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.688 \text{ kmol}}{5.256 \text{ kmol}} = 0.892 \text{ or } \mathbf{89.2\%}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.568 \text{ kmol}}{5.256 \text{ kmol}} = 0.108 \text{ or } \mathbf{10.8\%}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{5.256 \text{ kmol}} = 19.03 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{19.03 \text{ kg/kmol}} = \mathbf{0.437 \text{ kJ/kg} \cdot \text{K}}$$

**13-14** The mole numbers of the constituents of a gas mixture are given. The mass of each gas and the apparent gas constant are to be determined.

**Properties** The molar masses of  $H_2$ , and  $N_2$  are 2.0 and 28.0 kg/kmol, respectively (Table A-1)

**Analysis** The mass of each component is determined from

$$N_{H_2} = 8 \text{ kmol} \longrightarrow m_{H_2} = N_{H_2} M_{H_2} = (8 \text{ kmol})(2.0 \text{ kg/kmol}) = \mathbf{16 \text{ kg}}$$

$$N_{N_2} = 2 \text{ kmol} \longrightarrow m_{N_2} = N_{N_2} M_{N_2} = (2 \text{ kmol})(28 \text{ kg/kmol}) = \mathbf{56 \text{ kg}}$$

8 kmol  $H_2$   
 2 kmol  $N_2$

The total mass and the total number of moles are

$$m_m = m_{H_2} + m_{N_2} = 16 \text{ kg} + 56 \text{ kg} = 72 \text{ kg}$$

$$N_m = N_{H_2} + N_{N_2} = 8 \text{ kmol} + 2 \text{ kmol} = 10 \text{ kmol}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{72 \text{ kg}}{10 \text{ kmol}} = 7.2 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{7.2 \text{ kg/kmol}} = \mathbf{1.155 \text{ kJ/kg} \cdot \text{K}}$$

**13-15E** The mole numbers of the constituents of a gas mixture are given. The mass of each gas and the apparent gas constant are to be determined.

**Properties** The molar masses of  $H_2$ , and  $N_2$  are 2.0 and 28.0 lbm/lbmol, respectively (Table A-1E).

**Analysis** The mass of each component is determined from

$$N_{H_2} = 5 \text{ lbmol} \longrightarrow m_{H_2} = N_{H_2} M_{H_2} = (5 \text{ lbmol})(2.0 \text{ lbm/lbmol}) = \mathbf{10 \text{ lbm}}$$

$$N_{N_2} = 4 \text{ lbmol} \longrightarrow m_{N_2} = N_{N_2} M_{N_2} = (4 \text{ lbmol})(28 \text{ lbm/lbmol}) = \mathbf{112 \text{ lbm}}$$

5 lbmol  $H_2$   
 4 lbmol  $N_2$

The total mass and the total number of moles are

$$m_m = m_{H_2} + m_{N_2} = 10 \text{ lbm} + 112 \text{ lbm} = 122 \text{ lbm}$$

$$N_m = N_{H_2} + N_{N_2} = 5 \text{ lbmol} + 4 \text{ lbmol} = 9 \text{ lbmol}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{122 \text{ lbm}}{9 \text{ lbmol}} = 13.56 \text{ lbm/lbmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{1.986 \text{ Btu/lbmol} \cdot \text{R}}{13.56 \text{ lbm/lbmol}} = \mathbf{0.1465 \text{ Btu/lbm} \cdot \text{R}}$$

**13-16** The mass fractions of the constituents of a gas mixture are given. The volumetric analysis of the mixture and the apparent gas constant are to be determined.

**Properties** The molar masses of O<sub>2</sub>, N<sub>2</sub> and CO<sub>2</sub> are 32.0, 28, and 44.0 kg/kmol, respectively (Table A-1)

**Analysis** For convenience, consider 100 kg of the mixture. Then the number of moles of each component and the total number of moles are

$$m_{\text{O}_2} = 20 \text{ kg} \longrightarrow N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{20 \text{ kg}}{32 \text{ kg/kmol}} = 0.625 \text{ kmol}$$

$$m_{\text{N}_2} = 20 \text{ kg} \longrightarrow N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{30 \text{ kg}}{28 \text{ kg/kmol}} = 1.071 \text{ kmol}$$

$$m_{\text{CO}_2} = 50 \text{ kg} \longrightarrow N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{50 \text{ kg}}{44 \text{ kg/kmol}} = 1.136 \text{ kmol}$$

$$N_m = N_{\text{O}_2} + N_{\text{N}_2} + N_{\text{CO}_2} = 0.625 + 1.071 + 1.136 = 2.832 \text{ kmol}$$

|                     |
|---------------------|
| mass                |
| 20% O <sub>2</sub>  |
| 30% N <sub>2</sub>  |
| 50% CO <sub>2</sub> |

Noting that the volume fractions are same as the mole fractions, the volume fraction of each component becomes

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.625 \text{ kmol}}{2.832 \text{ kmol}} = 0.221 \text{ or } \mathbf{22.1\%}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{1.071 \text{ kmol}}{2.832 \text{ kmol}} = 0.378 \text{ or } \mathbf{37.8\%}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{1.136 \text{ kmol}}{2.832 \text{ kmol}} = 0.401 \text{ or } \mathbf{40.1\%}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{2.832 \text{ kmol}} = 35.31 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{35.31 \text{ kg/kmol}} = \mathbf{0.235 \text{ kJ/kg} \cdot \text{K}}$$

### ***P-v-T* Behavior of Gas Mixtures**

**13-17C** Normally yes. Air, for example, behaves as an ideal gas in the range of temperatures and pressures at which oxygen and nitrogen behave as ideal gases.

**13-18C** The pressure of a gas mixture is equal to the sum of the pressures each gas would exert if existed alone at the mixture temperature and volume. This law holds exactly for ideal gas mixtures, but only approximately for real gas mixtures.

**13-19C** The volume of a gas mixture is equal to the sum of the volumes each gas would occupy if existed alone at the mixture temperature and pressure. This law holds exactly for ideal gas mixtures, but only approximately for real gas mixtures.

**13-20C** The  $P$ - $v$ - $T$  behavior of a component in an ideal gas mixture is expressed by the ideal gas equation of state using the properties of the individual component instead of the mixture,  $P_i v_i = R_i T_i$ . The  $P$ - $v$ - $T$  behavior of a component in a real gas mixture is expressed by more complex equations of state, or by  $P_i v_i = Z_i R_i T_i$ , where  $Z_i$  is the compressibility factor.

**13-21C** Component pressure is the pressure a component would exert if existed alone at the mixture temperature and volume. Partial pressure is the quantity  $y_i P_m$ , where  $y_i$  is the mole fraction of component  $i$ . These two are identical for ideal gases.

**13-22C** Component volume is the volume a component would occupy if existed alone at the mixture temperature and pressure. Partial volume is the quantity  $y_i v_m$ , where  $y_i$  is the mole fraction of component  $i$ . These two are identical for ideal gases.

**13-23C** The one with the highest mole number.

**13-24C** The partial pressures will decrease but the pressure fractions will remain the same.

**13-25C** The partial pressures will increase but the pressure fractions will remain the same.

**13-26C** No. The correct expression is “the volume of a gas mixture is equal to the sum of the volumes each gas would occupy if existed alone at the mixture temperature and pressure.”

**13-27C** No. The correct expression is “the temperature of a gas mixture is equal to the temperature of the individual gas components.”

**13-28C** Yes, it is correct.

**13-29C** With Kay's rule, a real-gas mixture is treated as a pure substance whose critical pressure and temperature are defined in terms of the critical pressures and temperatures of the mixture components as

$$P'_{cr,m} = \sum y_i P_{cr,i} \quad \text{and} \quad T'_{cr,m} = \sum y_i T_{cr,i}$$

The compressibility factor of the mixture ( $Z_m$ ) is then easily determined using these pseudo-critical point values.

**13-30** A tank contains a mixture of two gases of known masses at a specified pressure and temperature. The mixture is now heated to a specified temperature. The volume of the tank and the final pressure of the mixture are to be determined.

**Assumptions** Under specified conditions both Ar and N<sub>2</sub> can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Analysis** The total number of moles is

$$N_m = N_{Ar} + N_{N_2} = 0.5 \text{ kmol} + 2 \text{ kmol} = 2.5 \text{ kmol}$$

and

$$\nu_m = \frac{N_m R_u T_m}{P_m} = \frac{(2.5 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(280 \text{ K})}{250 \text{ kPa}} = 23.3 \text{ m}^3$$

Also,

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{400 \text{ K}}{280 \text{ K}} (250 \text{ kPa}) = 357.1 \text{ kPa}$$

**13-31** The masses of the constituents of a gas mixture at a specified pressure and temperature are given. The partial pressure of each gas and the apparent molar mass of the gas mixture are to be determined.

**Assumptions** Under specified conditions both  $\text{CO}_2$  and  $\text{CH}_4$  can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Properties** The molar masses of  $\text{CO}_2$  and  $\text{CH}_4$  are 44.0 and 16.0 kg/kmol, respectively (Table A-1)

**Analysis** The mole numbers of the constituents are

$$m_{\text{CO}_2} = 1 \text{ kg} \longrightarrow N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.0227 \text{ kmol}$$

$$m_{\text{CH}_4} = 3 \text{ kg} \longrightarrow N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{3 \text{ kg}}{16 \text{ kg/kmol}} = 0.1875 \text{ kmol}$$

$$N_m = N_{\text{CO}_2} + N_{\text{CH}_4} = 0.0227 \text{ kmol} + 0.1875 \text{ kmol} = 0.2102 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.0227 \text{ kmol}}{0.2102 \text{ kmol}} = 0.108$$

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{0.1875 \text{ kmol}}{0.2102 \text{ kmol}} = 0.892$$

1 kg  $\text{CO}_2$   
3 kg  $\text{CH}_4$

300 K  
200 kPa

Then the partial pressures become

$$P_{\text{CO}_2} = y_{\text{CO}_2} P_m = (0.108)(200 \text{ kPa}) = \mathbf{21.6 \text{ kPa}}$$

$$P_{\text{CH}_4} = y_{\text{CH}_4} P_m = (0.892)(200 \text{ kPa}) = \mathbf{178.4 \text{ kPa}}$$

The apparent molar mass of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{4 \text{ kg}}{0.2102 \text{ kmol}} = \mathbf{19.03 \text{ kg/kmol}}$$

**13-32** The masses of the constituents of a gas mixture at a specified temperature are given. The partial pressure of each gas and the total pressure of the mixture are to be determined.

**Assumptions** Under specified conditions both  $\text{N}_2$  and  $\text{O}_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Analysis** The partial pressures of constituent gases are

$$P_{\text{N}_2} = \left( \frac{mRT}{V} \right)_{\text{N}_2} = \frac{(0.6 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})}{0.3 \text{ m}^3} = \mathbf{178.1 \text{ kPa}}$$

$$P_{\text{O}_2} = \left( \frac{mRT}{V} \right)_{\text{O}_2} = \frac{(0.4 \text{ kg})(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})}{0.3 \text{ m}^3} = \mathbf{103.9 \text{ kPa}}$$

0.3  $\text{m}^3$   
0.6 kg  $\text{N}_2$   
0.4 kg  $\text{O}_2$   
300 K

and

$$P_m = P_{\text{N}_2} + P_{\text{O}_2} = 178.1 \text{ kPa} + 103.9 \text{ kPa} = \mathbf{282.0 \text{ kPa}}$$

**13-33** The masses, temperatures, and pressures of two gases contained in two tanks connected to each other are given. The valve connecting the tanks is opened and the final temperature is measured. The volume of each tank and the final pressure are to be determined.

**Assumptions** Under specified conditions both  $N_2$  and  $O_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture

**Properties** The molar masses of  $N_2$  and  $O_2$  are 28.0 and 32.0 kg/kmol, respectively (Table A-1)

**Analysis** The volumes of the tanks are

$$V_{N_2} = \left( \frac{mRT}{P} \right)_{N_2} = \frac{(1 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{300 \text{ kPa}} = \mathbf{0.295 \text{ m}^3}$$

$$V_{O_2} = \left( \frac{mRT}{P} \right)_{O_2} = \frac{(3 \text{ kg})(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{500 \text{ kPa}} = \mathbf{0.465 \text{ m}^3}$$

$$V_{\text{total}} = V_{N_2} + V_{O_2} = 0.295 \text{ m}^3 + 0.465 \text{ m}^3 = 0.76 \text{ m}^3$$

Also,

$$m_{N_2} = 1 \text{ kg} \longrightarrow N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1 \text{ kg}}{28 \text{ kg/kmol}} = 0.03571 \text{ kmol}$$

$$m_{O_2} = 3 \text{ kg} \longrightarrow N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{3 \text{ kg}}{32 \text{ kg/kmol}} = 0.09375 \text{ kmol}$$

$$N_m = N_{N_2} + N_{O_2} = 0.03571 \text{ kmol} + 0.09375 \text{ kmol} = 0.1295 \text{ kmol}$$

Thus,

$$P_m = \left( \frac{NR_u T}{V} \right)_m = \frac{(0.1295 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(298 \text{ K})}{0.76 \text{ m}^3} = \mathbf{422.2 \text{ kPa}}$$

**13-34** A container contains a mixture of two fluids whose volumes are given. The density of the mixture is to be determined.

**Assumptions** The volume of the mixture is the sum of the volumes of the two constituents.

**Properties** The specific volumes of the two fluids are given to be  $0.0003 \text{ m}^3/\text{kg}$  and  $0.00023 \text{ m}^3/\text{kg}$ .

**Analysis** The mass of the two fluids are

$$m_A = \frac{V_A}{v_A} = \frac{0.001 \text{ m}^3}{0.0003 \text{ m}^3/\text{kg}} = 3.333 \text{ kg}$$

$$m_B = \frac{V_B}{v_B} = \frac{0.002 \text{ m}^3}{0.00023 \text{ m}^3/\text{kg}} = 8.696 \text{ kg}$$

The density of the mixture is then

$$\rho = \frac{m_A + m_B}{V_A + V_B} = \frac{(3.333 + 8.696) \text{ lbf}}{(0.001 + 0.002) \text{ ft}^3} = \mathbf{4010 \text{ kg/m}^3}$$

**13-35E** A mixture is obtained by mixing two gases at constant pressure and temperature. The volume and specific volume of the mixture are to be determined.

**Properties** The densities of two gases are given in the problem statement.

**Analysis** The volume of constituent gas A is

$$V_A = \frac{m_A}{\rho_A} = \frac{1 \text{ lbm}}{0.001 \text{ lbm/ft}^3} = 1000 \text{ ft}^3$$

and the volume of constituent gas B is

$$V_B = \frac{m_B}{\rho_B} = \frac{2 \text{ lbm}}{0.002 \text{ lbm/ft}^3} = 1000 \text{ ft}^3$$

Hence, the volume of the mixture is

$$V = V_A + V_B = 1000 + 1000 = \mathbf{2000 \text{ ft}^3}$$

The specific volume of the mixture will then be

$$v = \frac{V}{m} = \frac{2000 \text{ ft}^3}{(1+2) \text{ lbm}} = \mathbf{666.7 \text{ ft}^3/\text{lbm}}$$

1 lbm gas A

2 lbm gas B

**13-36** The masses of components of a gas mixture are given. The apparent molecular weight of this mixture, the volume it occupies, the partial volume of the oxygen, and the partial pressure of the helium are to be determined.

**Properties** The molar masses of  $O_2$ ,  $CO_2$ , and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1).

**Analysis** The total mass of the mixture is

$$m_m = m_{O_2} + m_{CO_2} + m_{He} = 0.1 + 1 + 0.5 = 1.6 \text{ kg}$$

The mole numbers of each component are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{0.1 \text{ kg}}{32 \text{ kg/kmol}} = 0.003125 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.02273 \text{ kmol}$$

$$N_{He} = \frac{m_{He}}{M_{He}} = \frac{0.5 \text{ kg}}{4 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

|                                          |
|------------------------------------------|
| 0.1 kg $O_2$<br>1 kg $CO_2$<br>0.5 kg He |
|------------------------------------------|

The mole number of the mixture is

$$N_m = N_{O_2} + N_{CO_2} + N_{He} = 0.003125 + 0.02273 + 0.125 = 0.15086 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{1.6 \text{ kg}}{0.15086 \text{ kmol}} = \mathbf{10.61 \text{ kg/kmol}}$$

The volume of this ideal gas mixture is

$$V_m = \frac{N_m R_u T}{P} = \frac{(0.1509 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(300 \text{ K})}{100 \text{ kPa}} = \mathbf{3.764 \text{ m}^3}$$

The partial volume of oxygen in the mixture is

$$V_{O_2} = y_{O_2} V_m = \frac{N_{O_2}}{N_m} V_m = \frac{0.003125 \text{ kmol}}{0.1509 \text{ kmol}} (3.764 \text{ m}^3) = \mathbf{0.07795 \text{ m}^3}$$

The partial pressure of helium in the mixture is

$$P_{He} = y_{He} P_m = \frac{N_{He}}{N_m} P_m = \frac{0.125 \text{ kmol}}{0.1509 \text{ kmol}} (100 \text{ kPa}) = \mathbf{82.84 \text{ kPa}}$$

**13-37** The mass fractions of components of a gas mixture are given. The mole fractions of each constituent, the mixture's apparent molecular weight, the partial pressure of each constituent, and the apparent specific heats of the mixture are to be determined.

**Properties** The molar masses of  $N_2$ , He,  $CH_4$ , and  $C_2H_6$  are 28.0, 4.0, 16.0, and 30.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 1.039, 5.1926, 2.2537, and 1.7662 kJ/kg·K, respectively (Table A-2a).

**Analysis** We consider 100 kg of this mixture. The mole numbers of each component are

$$\begin{aligned} N_{N_2} &= \frac{m_{N_2}}{M_{N_2}} = \frac{15 \text{ kg}}{28 \text{ kg/kmol}} = 0.5357 \text{ kmol} \\ N_{He} &= \frac{m_{He}}{M_{He}} = \frac{5 \text{ kg}}{4 \text{ kg/kmol}} = 1.25 \text{ kmol} \\ N_{CH_4} &= \frac{m_{CH_4}}{M_{CH_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol} \\ N_{C_2H_6} &= \frac{m_{C_2H_6}}{M_{C_2H_6}} = \frac{20 \text{ kg}}{30 \text{ kg/kmol}} = 0.6667 \text{ kmol} \end{aligned}$$

|                                                               |
|---------------------------------------------------------------|
| 15% $N_2$<br>5% He<br>60% $CH_4$<br>20% $C_2H_6$<br>(by mass) |
|---------------------------------------------------------------|

The mole number of the mixture is

$$N_m = N_{N_2} + N_{He} + N_{CH_4} + N_{C_2H_6} = 0.5357 + 1.25 + 3.75 + 0.6667 = 6.2024 \text{ kmol}$$

and the mole fractions are

$$\begin{aligned} y_{N_2} &= \frac{N_{N_2}}{N_m} = \frac{0.5357 \text{ kmol}}{6.2024 \text{ kmol}} = \mathbf{0.08637} \\ y_{He} &= \frac{N_{He}}{N_m} = \frac{1.25 \text{ kmol}}{6.2024 \text{ kmol}} = \mathbf{0.2015} \\ y_{CH_4} &= \frac{N_{CH_4}}{N_m} = \frac{3.75 \text{ kmol}}{6.2024 \text{ kmol}} = \mathbf{0.6046} \\ y_{C_2H_6} &= \frac{N_{C_2H_6}}{N_m} = \frac{0.6667 \text{ kmol}}{6.2024 \text{ kmol}} = \mathbf{0.1075} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{6.2024 \text{ kmol}} = \mathbf{16.12 \text{ kg/kmol}}$$

The partial pressure of each constituent for a mixture pressure of 1200 kPa are

$$\begin{aligned} P_{N_2} &= y_{N_2} P_m = (0.08637)(1200 \text{ kPa}) = \mathbf{103.6 \text{ kPa}} \\ P_{He} &= y_{He} P_m = (0.2015)(1200 \text{ kPa}) = \mathbf{241.8 \text{ kPa}} \\ P_{CH_4} &= y_{CH_4} P_m = (0.6046)(1200 \text{ kPa}) = \mathbf{725.5 \text{ kPa}} \\ P_{C_2H_6} &= y_{C_2H_6} P_m = (0.1075)(1200 \text{ kPa}) = \mathbf{129.0 \text{ kPa}} \end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{He} c_{p,He} + mf_{CH_4} c_{p,CH_4} + mf_{C_2H_6} c_{p,C_2H_6} \\ &= 0.15 \times 1.039 + 0.05 \times 5.1926 + 0.60 \times 2.2537 + 0.20 \times 1.7662 = \mathbf{2.121 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{16.12 \text{ kg/kmol}} = 0.5158 \text{ kJ/kg} \cdot \text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 2.121 - 0.5158 = \mathbf{1.605 \text{ kJ/kg} \cdot \text{K}}$$

**13-38** The volume fractions of components of a gas mixture are given. The mixture's apparent molecular weight and the apparent specific heats of the mixture are to be determined.

**Properties** The molar masses of O<sub>2</sub>, N<sub>2</sub>, CO<sub>2</sub>, and CH<sub>4</sub> are 32.0, 28.0, 44.0, and 16.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 0.918, 1.039, 0.846, and 2.2537 kJ/kg·K, respectively (Table A-2).

**Analysis** We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned}m_{\text{O}_2} &= N_{\text{O}_2} M_{\text{O}_2} = (30 \text{ kmol})(32 \text{ kg/kmol}) = 960 \text{ kg} \\m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (40 \text{ kmol})(28 \text{ kg/kmol}) = 1120 \text{ kg} \\m_{\text{CO}_2} &= N_{\text{CO}_2} M_{\text{CO}_2} = (10 \text{ kmol})(44 \text{ kg/kmol}) = 440 \text{ kg} \\m_{\text{CH}_4} &= N_{\text{CH}_4} M_{\text{CH}_4} = (20 \text{ kmol})(16 \text{ kg/kmol}) = 320 \text{ kg}\end{aligned}$$

The total mass is

$$\begin{aligned}m_m &= m_{\text{O}_2} + m_{\text{N}_2} + m_{\text{CO}_2} + m_{\text{CH}_4} \\&= 960 + 1120 + 440 + 320 = 2840 \text{ kg}\end{aligned}$$

Then the mass fractions are

$$\begin{aligned}\text{mf}_{\text{O}_2} &= \frac{m_{\text{O}_2}}{m_m} = \frac{960 \text{ kg}}{2840 \text{ kg}} = 0.3380 \\ \text{mf}_{\text{N}_2} &= \frac{m_{\text{N}_2}}{m_m} = \frac{1120 \text{ kg}}{2840 \text{ kg}} = 0.3944 \\ \text{mf}_{\text{CO}_2} &= \frac{m_{\text{CO}_2}}{m_m} = \frac{440 \text{ kg}}{2840 \text{ kg}} = 0.1549 \\ \text{mf}_{\text{CH}_4} &= \frac{m_{\text{CH}_4}}{m_m} = \frac{320 \text{ kg}}{2840 \text{ kg}} = 0.1127\end{aligned}$$

30% O<sub>2</sub>  
40% N<sub>2</sub>  
10% CO<sub>2</sub>  
20% CH<sub>4</sub>  
(by volume)

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2840 \text{ kg}}{100 \text{ kmol}} = \mathbf{28.40 \text{ kg/kmol}}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned}c_p &= \text{mf}_{\text{O}_2} c_{p,\text{O}_2} + \text{mf}_{\text{N}_2} c_{p,\text{N}_2} + \text{mf}_{\text{CO}_2} c_{p,\text{CO}_2} + \text{mf}_{\text{CH}_4} c_{p,\text{CH}_4} \\&= 0.3380 \times 0.918 + 0.3944 \times 1.039 + 0.1549 \times 0.846 + 0.1127 \times 2.2537 \\&= \mathbf{1.1051 \text{ kJ/kg} \cdot \text{K}}\end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.40 \text{ kg/kmol}} = 0.2927 \text{ kJ/kg} \cdot \text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 1.1051 - 0.2927 = \mathbf{0.8124 \text{ kJ/kg} \cdot \text{K}}$$

**13-39** The mass fractions of components of a gas mixture are given. The volume occupied by 100 kg of this mixture is to be determined.

**Properties** The molar masses of  $\text{CH}_4$ ,  $\text{C}_3\text{H}_8$ , and  $\text{C}_4\text{H}_{10}$  are 16.0, 44.0, and 58.0 kg/kmol, respectively (Table A-1).

**Analysis** The mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_3\text{H}_8} = \frac{m_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.5682 \text{ kmol}$$

$$N_{\text{C}_4\text{H}_{10}} = \frac{m_{\text{C}_4\text{H}_{10}}}{M_{\text{C}_4\text{H}_{10}}} = \frac{15 \text{ kg}}{58 \text{ kg/kmol}} = 0.2586 \text{ kmol}$$

60%  $\text{CH}_4$   
 25%  $\text{C}_3\text{H}_8$   
 15%  $\text{C}_4\text{H}_{10}$   
 (by mass)

The mole number of the mixture is

$$N_m = N_{\text{CH}_4} + N_{\text{C}_3\text{H}_8} + N_{\text{C}_4\text{H}_{10}} = 3.75 + 0.5682 + 0.2586 = 4.5768 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{4.5768 \text{ kmol}} = 21.85 \text{ kg/kmol}$$

Then the volume of this ideal gas mixture is

$$V_m = \frac{N_m R_u T}{P} = \frac{(4.5768 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(310 \text{ K})}{3000 \text{ kPa}} = \mathbf{3.93 \text{ m}^3}$$

**13-40E** The mass fractions of components of a gas mixture are given. The mass of 5 ft<sup>3</sup> of this mixture and the partial volumes of the components are to be determined.

**Properties** The molar masses of N<sub>2</sub>, O<sub>2</sub>, and He are 28.0, 32.0, and 4.0 lbm/lbmol, respectively (Table A-1E).

**Analysis** We consider 100 lbm of this mixture for calculating the molar mass of the mixture. The mole numbers of each component are

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{60 \text{ lbm}}{28 \text{ lbm/lbmol}} = 2.1429 \text{ lbmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{30 \text{ lbm}}{32 \text{ lbm/lbmol}} = 0.9375 \text{ lbmol}$$

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{10 \text{ lbm}}{4 \text{ lbm/lbmol}} = 2.5 \text{ lbmol}$$

|                                                                                      |
|--------------------------------------------------------------------------------------|
| 5 ft <sup>3</sup><br>60% N <sub>2</sub><br>30% O <sub>2</sub><br>10% He<br>(by mass) |
|--------------------------------------------------------------------------------------|

The mole number of the mixture is

$$N_m = N_{\text{N}_2} + N_{\text{O}_2} + N_{\text{He}} = 2.1429 + 0.9375 + 2.5 = 5.5804 \text{ lbmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{5.5804 \text{ lbmol}} = 17.92 \text{ lbm/lbmol}$$

Then the mass of this ideal gas mixture is

$$m = \frac{P V M_m}{R_u T} = \frac{(300 \text{ psia})(5 \text{ ft}^3)(17.92 \text{ lbm/lbmol})}{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(530 \text{ R})} = \mathbf{4.727 \text{ lbm}}$$

The mole fractions are

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{2.1429 \text{ lbmol}}{5.5804 \text{ lbmol}} = 0.3840$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.9375 \text{ lbmol}}{5.5804 \text{ lbmol}} = 0.1680$$

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_m} = \frac{2.5 \text{ lbmol}}{5.5804 \text{ lbmol}} = 0.4480$$

Noting that volume fractions are equal to mole fractions, the partial volumes are determined from

$$V_{\text{N}_2} = y_{\text{N}_2} V_m = (0.3840)(5 \text{ ft}^3) = \mathbf{1.92 \text{ ft}^3}$$

$$V_{\text{O}_2} = y_{\text{O}_2} V_m = (0.1680)(5 \text{ ft}^3) = \mathbf{0.84 \text{ ft}^3}$$

$$V_{\text{He}} = y_{\text{He}} V_m = (0.4480)(5 \text{ ft}^3) = \mathbf{2.24 \text{ ft}^3}$$

**13-41** The mass fractions of components of a gas mixture are given. The partial pressure of ethane is to be determined.

**Properties** The molar masses of  $\text{CH}_4$  and  $\text{C}_2\text{H}_6$  are 16.0 and 30.0 kg/kmol, respectively (Table A-1).

**Analysis** We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{70 \text{ kg}}{16 \text{ kg/kmol}} = 4.375 \text{ kmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{30 \text{ kg}}{30 \text{ kg/kmol}} = 1.0 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6} = 4.375 + 1.0 = 5.375 \text{ kmol}$$

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.375 \text{ kmol}}{5.375 \text{ kmol}} = 0.8139$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{1.0 \text{ kmol}}{5.375 \text{ kmol}} = 0.1861$$

The final pressure of ethane in the final mixture is

$$P_{\text{C}_2\text{H}_6} = y_{\text{C}_2\text{H}_6} P_m = (0.1861)(130 \text{ kPa}) = \mathbf{24.19 \text{ kPa}}$$

**13-42E** The Orsat analysis (molar fractions) of components of a gas mixture are given. The mass flow rate of the mixture is to be determined.

**Properties** The molar masses of  $\text{CO}_2$ ,  $\text{O}_2$ ,  $\text{N}_2$ , and  $\text{CO}$  are 44.0, 32.0, 28.0, and 28.0 lbm/lbmol, respectively (Table A-1E).

**Analysis** The molar fraction of  $\text{N}_2$  is

$$y_{\text{N}_2} = 1 - y_{\text{CO}_2} - y_{\text{O}_2} - y_{\text{CO}} = 1 - 0.15 - 0.15 - 0.01 = 0.69$$

The molar mass of the mixture is determined from

$$\begin{aligned} M_m &= y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{O}_2} M_{\text{O}_2} + y_{\text{CO}} M_{\text{CO}} + y_{\text{N}_2} M_{\text{N}_2} \\ &= 0.15 \times 44 + 0.15 \times 32 + 0.01 \times 28 + 0.69 \times 28 \\ &= 31.00 \text{ lbm/lbmol} \end{aligned}$$

The specific volume of the mixture is

$$\nu = \frac{R_u T}{M_m P} = \frac{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(660 \text{ R})}{(31.00 \text{ lbm/lbmol})(14.7 \text{ psia})} = 15.54 \text{ ft}^3/\text{lbm}$$

The mass flow rate of these gases is then

$$\dot{m} = \frac{AV}{\nu} = \frac{(10 \text{ ft}^2)(20 \text{ ft/s})}{15.54 \text{ ft}^3/\text{lbm}} = \mathbf{12.87 \text{ lbm/s}}$$

|------------------------------------------------------------------------------------------------------------------|

The partial pressures after the separation unit are

$$\begin{aligned}P_{\text{CH}_4} &= y_{\text{CH}_4} P_m = (0.7425)(100 \text{ kPa}) = 74.25 \text{ kPa} \\P_{\text{C}_2\text{H}_6} &= y_{\text{C}_2\text{H}_6} P_m = (0.2475)(100 \text{ kPa}) = 24.75 \text{ kPa} \\P_{\text{C}_3\text{H}_8} &= y_{\text{C}_3\text{H}_8} P_m = (0.01)(100 \text{ kPa}) = 1 \text{ kPa}\end{aligned}$$

The changes in partial pressures are then

$$\begin{aligned}\Delta P_{\text{CH}_4} &= 74.25 - 60 = \mathbf{14.25 \text{ kPa}} \\ \Delta P_{\text{C}_2\text{H}_6} &= 24.75 - 20 = \mathbf{4.75 \text{ kPa}} \\ \Delta P_{\text{C}_3\text{H}_8} &= 1 - 10 = \mathbf{-9 \text{ kPa}}\end{aligned}$$

**13-44** The partial pressure of R-134a in atmospheric air to form a 100-ppm contaminant is to be determined.

**Analysis** Noting that volume fractions and mole fractions are equal, the molar fraction of R-134a in air is

$$y_{\text{R134a}} = \frac{100}{10^6} = 0.0001$$

The partial pressure of R-134a in air is then

$$P_{\text{R134a}} = y_{\text{R134a}} P_m = (0.0001)(100 \text{ kPa}) = \mathbf{0.01 \text{ kPa}}$$

**13-45E** The volumetric analysis of a mixture of gases is given. The volumetric and mass flow rates are to be determined using three methods.

**Properties** The molar masses of  $O_2$ ,  $N_2$ ,  $CO_2$ , and  $CH_4$  are 32.0, 28.0, 44.0, and 16.0 lbm/lbmol, respectively (Table A-1E).

**Analysis** (a) We consider 100 lbmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{O_2} &= N_{O_2} M_{O_2} = (30 \text{ lbmol})(32 \text{ lbm/lbmol}) = 960 \text{ lbm} \\ m_{N_2} &= N_{N_2} M_{N_2} = (40 \text{ lbmol})(28 \text{ lbm/lbmol}) = 1120 \text{ lbm} \\ m_{CO_2} &= N_{CO_2} M_{CO_2} = (10 \text{ lbmol})(44 \text{ lbm/lbmol}) = 440 \text{ lbm} \\ m_{CH_4} &= N_{CH_4} M_{CH_4} = (20 \text{ lbmol})(16 \text{ lbm/lbmol}) = 320 \text{ lbm} \end{aligned}$$

The total mass is

$$\begin{aligned} m_m &= m_{O_2} + m_{N_2} + m_{CO_2} + m_{CH_4} \\ &= 960 + 1120 + 440 + 320 = 2840 \text{ lbm} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2840 \text{ lbm}}{100 \text{ lbmol}} = 28.40 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R}}{28.40 \text{ lbm/lbmol}} = 0.3778 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$$

The specific volume of the mixture is

$$\nu = \frac{RT}{P} = \frac{(0.3778 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(530 \text{ R})}{1500 \text{ psia}} = 0.1335 \text{ ft}^3/\text{lbm}$$

The volume flow rate is

$$\dot{V} = AV = \frac{\pi D^2}{4} V = \frac{\pi (1/12 \text{ ft})^2}{4} (10 \text{ ft/s}) = \mathbf{0.05454 \text{ ft}^3/\text{s}}$$

and the mass flow rate is

$$\dot{m} = \frac{\dot{V}}{\nu} = \frac{0.05454 \text{ ft}^3/\text{s}}{0.1335 \text{ ft}^3/\text{lbm}} = \mathbf{0.4085 \text{ lbm/s}}$$

(b) To use the Amagat's law for this real gas mixture, we first need the mole fractions and the  $Z$  of each component at the mixture temperature and pressure. The compressibility factors are obtained using Fig. A-15 to be

$$\left. \begin{aligned} T_{R,O_2} &= \frac{T_m}{T_{cr,O_2}} = \frac{530 \text{ R}}{278.6 \text{ R}} = 1.902 \\ P_{R,O_2} &= \frac{P_m}{P_{cr,O_2}} = \frac{1500 \text{ psia}}{736 \text{ psia}} = 2.038 \end{aligned} \right\} Z_{O_2} = 0.94$$

$$\left. \begin{aligned} T_{R,N_2} &= \frac{530 \text{ R}}{227.1 \text{ R}} = 2.334 \\ P_{R,N_2} &= \frac{1500 \text{ psia}}{492 \text{ psia}} = 3.049 \end{aligned} \right\} Z_{N_2} = 0.99$$

$$\left. \begin{aligned} T_{R,\text{CO}_2} &= \frac{530 \text{ R}}{547.5 \text{ R}} = 0.968 \\ P_{R,\text{CO}_2} &= \frac{1500 \text{ psia}}{1071 \text{ psia}} = 1.401 \end{aligned} \right\} Z_{\text{CO}_2} = 0.21 \quad \left. \begin{aligned} T_{R,\text{CH}_4} &= \frac{530 \text{ R}}{343.9 \text{ R}} = 1.541 \\ P_{R,\text{CH}_4} &= \frac{1500 \text{ psia}}{673 \text{ psia}} = 2.229 \end{aligned} \right\} Z_{\text{CH}_4} = 0.85$$

and

$$\begin{aligned} Z_m &= \sum y_i Z_i = y_{\text{O}_2} Z_{\text{O}_2} + y_{\text{N}_2} Z_{\text{N}_2} + y_{\text{CO}_2} Z_{\text{CO}_2} + y_{\text{CH}_4} Z_{\text{CH}_4} \\ &= (0.30)(0.94) + (0.40)(0.99) + (0.10)(0.21) + (0.20)(0.85) = 0.869 \end{aligned}$$

Then,

$$\nu = \frac{Z_m RT}{P} = \frac{(0.869)(0.3778 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(530 \text{ R})}{1500 \text{ psia}} = 0.1160 \text{ ft}^3/\text{lbm}$$

$$\dot{\nu} = 0.05454 \text{ ft}^3/\text{s}$$

$$\dot{m} = \frac{\dot{\nu}}{\nu} = \frac{0.05454 \text{ ft}^3/\text{s}}{0.1160 \text{ ft}^3/\text{lbm}} = 0.4702 \text{ lbm/s}$$

(c) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of mixture gases.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{O}_2} T_{\text{cr},\text{O}_2} + y_{\text{N}_2} T_{\text{cr},\text{N}_2} + y_{\text{CO}_2} T_{\text{cr},\text{CO}_2} + y_{\text{CH}_4} T_{\text{cr},\text{CH}_4} \\ &= (0.30)(278.6 \text{ R}) + (0.40)(227.1 \text{ R}) + (0.10)(547.5 \text{ R}) + (0.20)(343.9 \text{ R}) = 298.0 \text{ R} \\ P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{O}_2} P_{\text{cr},\text{O}_2} + y_{\text{N}_2} P_{\text{cr},\text{N}_2} + y_{\text{CO}_2} P_{\text{cr},\text{CO}_2} + y_{\text{CH}_4} P_{\text{cr},\text{CH}_4} \\ &= (0.30)(736 \text{ psia}) + (0.40)(492 \text{ psia}) + (0.10)(1071 \text{ psia}) + (0.20)(673 \text{ psia}) = 659.3 \text{ psia} \end{aligned}$$

and

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{\text{cr},m}} = \frac{530 \text{ R}}{298.0 \text{ R}} = 1.779 \\ P_R &= \frac{P_m}{P'_{\text{cr},m}} = \frac{1500 \text{ psia}}{659.3 \text{ psia}} = 2.275 \end{aligned} \right\} Z_m = 0.915 \quad (\text{Fig. A-15})$$

Then,

$$\nu = \frac{Z_m RT}{P} = \frac{(0.915)(0.3778 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(530 \text{ R})}{1500 \text{ psia}} = 0.1221 \text{ ft}^3/\text{lbm}$$

$$\dot{\nu} = 0.05454 \text{ ft}^3/\text{s}$$

$$\dot{m} = \frac{\dot{\nu}}{\nu} = \frac{0.05454 \text{ ft}^3/\text{s}}{0.1221 \text{ ft}^3/\text{lbm}} = 0.4467 \text{ lbm/s}$$

**13-46** The volumes, temperatures, and pressures of two gases forming a mixture are given. The volume of the mixture is to be determined using three methods.

**Analysis** (a) Under specified conditions both O<sub>2</sub> and N<sub>2</sub> will considerably deviate from the ideal gas behavior. Treating the mixture as an ideal gas,

$$N_{O_2} = \left( \frac{P \mathcal{V}}{R_u T} \right)_{O_2} = \frac{(8000 \text{ kPa})(0.3 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})} = 1.443 \text{ kmol}$$

$$N_{N_2} = \left( \frac{P \mathcal{V}}{R_u T} \right)_{N_2} = \frac{(8000 \text{ kPa})(0.5 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})} = 2.406 \text{ kmol}$$

$$N_m = N_{O_2} + N_{N_2} = 1.443 \text{ kmol} + 2.406 \text{ kmol} = 3.849 \text{ kmol}$$

$$\mathcal{V}_m = \frac{N_m R_u T_m}{P_m} = \frac{(3.849 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})}{8000 \text{ kPa}} = \mathbf{0.8 \text{ m}^3}$$

(b) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of O<sub>2</sub> and N<sub>2</sub> from Table A-1. But we first need to determine the *Z* and the mole numbers of each component at the mixture temperature and pressure (Fig. A-15),

$$O_2: \left. \begin{aligned} T_{R,O_2} &= \frac{T_m}{T_{cr,O_2}} = \frac{200 \text{ K}}{154.8 \text{ K}} = 1.292 \\ P_{R,O_2} &= \frac{P_m}{P_{cr,O_2}} = \frac{8 \text{ MPa}}{5.08 \text{ MPa}} = 1.575 \end{aligned} \right\} Z_{O_2} = 0.77$$

$$N_2: \left. \begin{aligned} T_{R,N_2} &= \frac{T_m}{T_{cr,N_2}} = \frac{200 \text{ K}}{126.2 \text{ K}} = 1.585 \\ P_{R,N_2} &= \frac{P_m}{P_{cr,N_2}} = \frac{8 \text{ MPa}}{3.39 \text{ MPa}} = 2.360 \end{aligned} \right\} Z_{N_2} = 0.863$$

$$N_{O_2} = \left( \frac{P \mathcal{V}}{Z R_u T} \right)_{O_2} = \frac{(8000 \text{ kPa})(0.3 \text{ m}^3)}{(0.77)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})} = 1.874 \text{ kmol}$$

$$N_{N_2} = \left( \frac{P \mathcal{V}}{Z R_u T} \right)_{N_2} = \frac{(8000 \text{ kPa})(0.5 \text{ m}^3)}{(0.863)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})} = 2.787 \text{ kmol}$$

$$N_m = N_{O_2} + N_{N_2} = 1.874 \text{ kmol} + 2.787 \text{ kmol} = 4.661 \text{ kmol}$$

The mole fractions are

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{1.874 \text{ kmol}}{4.661 \text{ kmol}} = 0.402$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{2.787 \text{ kmol}}{4.661 \text{ kmol}} = 0.598$$

$$T'_{cr,m} = \sum y_i T_{cr,i} = y_{O_2} T_{cr,O_2} + y_{N_2} T_{cr,N_2} \\ = (0.402)(154.8 \text{ K}) + (0.598)(126.2 \text{ K}) = 137.7 \text{ K}$$

$$P'_{cr,m} = \sum y_i P_{cr,i} = y_{O_2} P_{cr,O_2} + y_{N_2} P_{cr,N_2} \\ = (0.402)(5.08 \text{ MPa}) + (0.598)(3.39 \text{ MPa}) = 4.07 \text{ MPa}$$

Then,

$$\left. \begin{aligned} T_R &= \frac{T_m}{T_{\text{cr},\text{O}_2}} = \frac{200 \text{ K}}{137.7 \text{ K}} = 1.452 \\ P_R &= \frac{P_m}{P_{\text{cr},\text{O}_2}} = \frac{8 \text{ MPa}}{4.07 \text{ MPa}} = 1.966 \end{aligned} \right\} Z_m = 0.82 \quad (\text{Fig. A-15})$$

Thus,

$$\nu_m = \frac{Z_m N_m R_u T_m}{P_m} = \frac{(0.82)(4.661 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})}{8000 \text{ kPa}} = \mathbf{0.79 \text{ m}^3}$$

(c) To use the Amagat's law for this real gas mixture, we first need the  $Z$  of each component at the mixture temperature and pressure, which are determined in part (b). Then,

$$Z_m = \sum y_i Z_i = y_{\text{O}_2} Z_{\text{O}_2} + y_{\text{N}_2} Z_{\text{N}_2} = (0.402)(0.77) + (0.598)(0.863) = 0.83$$

Thus,

$$\nu_m = \frac{Z_m N_m R_u T_m}{P_m} = \frac{(0.83)(4.661 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})}{8000 \text{ kPa}} = \mathbf{0.80 \text{ m}^3}$$

**13-47 [Also solved by EES on enclosed CD]** The mole numbers, temperatures, and pressures of two gases forming a mixture are given. The final temperature is also given. The pressure of the mixture is to be determined using two methods.

**Analysis** (a) Under specified conditions both Ar and N<sub>2</sub> will considerably deviate from the ideal gas behavior. Treating the mixture as an ideal gas,

$$\left. \begin{array}{l} \text{Initial state : } P_1 V_1 = N_1 R_u T_1 \\ \text{Final state : } P_2 V_2 = N_2 R_u T_2 \end{array} \right\} P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(4)(200 \text{ K})}{(1)(220 \text{ K})} (5 \text{ MPa}) = \mathbf{18.2 \text{ MPa}}$$

(b) Initially,

$$\left. \begin{array}{l} T_R = \frac{T_1}{T_{\text{cr,Ar}}} = \frac{220 \text{ K}}{151.0 \text{ K}} = 1.457 \\ P_R = \frac{P_1}{P_{\text{cr,Ar}}} = \frac{5 \text{ MPa}}{4.86 \text{ MPa}} = 1.0278 \end{array} \right\} Z_{\text{Ar}} = 0.90 \text{ (Fig. A-15)}$$

Then the volume of the tank is

$$V = \frac{Z N_{\text{Ar}} R_u T}{P} = \frac{(0.90)(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(220 \text{ K})}{5000 \text{ kPa}} = 0.33 \text{ m}^3$$

After mixing,

$$\left. \begin{array}{l} T_{R,\text{Ar}} = \frac{T_m}{T_{\text{cr,Ar}}} = \frac{200 \text{ K}}{151.0 \text{ K}} = 1.325 \\ \text{Ar: } V_{R,\text{Ar}} = \frac{V_{\text{Ar}}}{R_u T_{\text{cr,Ar}} / P_{\text{cr,Ar}}} = \frac{V_m / N_{\text{Ar}}}{R_u T_{\text{cr,Ar}} / P_{\text{cr,Ar}}} \\ \quad = \frac{(0.33 \text{ m}^3)/(1 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(151.0 \text{ K})/(4860 \text{ kPa})} = 1.278 \end{array} \right\} P_R = 0.90 \text{ (Fig. A-15)}$$

$$\left. \begin{array}{l} T_{R,\text{N}_2} = \frac{T_m}{T_{\text{cr,N}_2}} = \frac{200 \text{ K}}{126.2 \text{ K}} = 1.585 \\ \text{N}_2: V_{R,\text{N}_2} = \frac{V_{\text{N}_2}}{R_u T_{\text{cr,N}_2} / P_{\text{cr,N}_2}} = \frac{V_m / N_{\text{N}_2}}{R_u T_{\text{cr,N}_2} / P_{\text{cr,N}_2}} \\ \quad = \frac{(0.33 \text{ m}^3)/(3 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(126.2 \text{ K})/(3390 \text{ kPa})} = 0.355 \end{array} \right\} P_R = 3.75 \text{ (Fig. A-15)}$$

Thus,

$$P_{\text{Ar}} = (P_R P_{\text{cr}})_{\text{Ar}} = (0.90)(4.86 \text{ MPa}) = 4.37 \text{ MPa}$$

$$P_{\text{N}_2} = (P_R P_{\text{cr}})_{\text{N}_2} = (3.75)(3.39 \text{ MPa}) = 12.7 \text{ MPa}$$

and

$$P_m = P_{\text{Ar}} + P_{\text{N}_2} = 4.37 \text{ MPa} + 12.7 \text{ MPa} = \mathbf{17.1 \text{ MPa}}$$

**13-48 EES** Problem 13-47 is reconsidered. The effect of the moles of nitrogen supplied to the tank on the final pressure of the mixture is to be studied using the ideal-gas equation of state and the compressibility chart with Dalton's law.

**Analysis** The problem is solved using EES, and the solution is given below.

**"Input Data"**

$R_u = 8.314$  [kJ/kmol-K] "universal Gas Constant"  
 $T_{Ar} = 220$  [K]  
 $P_{Ar} = 5000$  [kPa] "Pressure for only Argon in the tank initially."  
 $N_{Ar} = 1$  [kmol]  
 $\{N_{N2} = 3$  [kmol] $\}$   
 $T_{mix} = 200$  [K]  
 $T_{cr,Ar} = 151.0$  [K] "Critical Constants are found in Table A.1 of the text"  
 $P_{cr,Ar} = 4860$  [kPa]  
 $T_{cr,N2} = 126.2$  [K]  
 $P_{cr,N2} = 3390$  [kPa]

**"Ideal-gas Solution:"**

$P_{Ar} V_{Tank\_IG} = N_{Ar} R_u T_{Ar}$  "Apply the ideal gas law the gas in the tank."  
 $P_{mix\_IG} V_{Tank\_IG} = N_{mix} R_u T_{mix}$  "Ideal-gas mixture pressure"  
 $N_{mix} = N_{Ar} + N_{N2}$  "Moles of mixture"

**"Real Gas Solution:"**

$P_{Ar} V_{Tank\_RG} = Z_{Ar\_1} N_{Ar} R_u T_{Ar}$  "Real gas volume of tank"  
 $T_R = T_{Ar} / T_{cr,Ar}$  "Initial reduced Temp. of Ar"  
 $P_R = P_{Ar} / P_{cr,Ar}$  "Initial reduced Press. of Ar"

**Properties of Gas Mixtures**

**13-49C** Yes. Yes (extensive property).

**13-50C** No (intensive property).

**13-51C** The answers are the same for entropy.

**13-52C** Yes. Yes (conservation of energy).

**13-53C** We have to use the partial pressure.

**13-54C** No, this is an approximate approach. It assumes a component behaves as if it existed alone at the mixture temperature and pressure (i.e., it disregards the influence of dissimilar molecules on each other.)

**13-55** Volumetric fractions of the constituents of a mixture are given. The mixture undergoes an adiabatic compression process. The makeup of the mixture on a mass basis and the internal energy change per unit mass of mixture are to be determined.

**Assumptions** Under specified conditions all  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{N}_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Properties 1** The molar masses of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{N}_2$  are 44.0, 28.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1). **2** The process is reversible.

**Analysis** Noting that volume fractions are equal to mole fractions in ideal gas mixtures, the molar mass of the mixture is determined to be

$$\begin{aligned} M_m &= y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{CO}} M_{\text{CO}} + y_{\text{O}_2} M_{\text{O}_2} + y_{\text{N}_2} M_{\text{N}_2} \\ &= (0.15)(44) + (0.05)(28) + (0.10)(32) + (0.70)(28) \\ &= 30.80 \text{ kg/kmol} \end{aligned}$$

The mass fractions are

$$\begin{aligned} \text{mf}_{\text{CO}_2} &= y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m} = (0.15) \frac{44 \text{ kg/kmol}}{30.80 \text{ kg/kmol}} = \mathbf{0.2143} \\ \text{mf}_{\text{CO}} &= y_{\text{CO}} \frac{M_{\text{CO}}}{M_m} = (0.05) \frac{28 \text{ kg/kmol}}{30.80 \text{ kg/kmol}} = \mathbf{0.0454} \\ \text{mf}_{\text{O}_2} &= y_{\text{O}_2} \frac{M_{\text{O}_2}}{M_m} = (0.10) \frac{32 \text{ kg/kmol}}{30.80 \text{ kg/kmol}} = \mathbf{0.1039} \\ \text{mf}_{\text{N}_2} &= y_{\text{N}_2} \frac{M_{\text{N}_2}}{M_m} = (0.70) \frac{28 \text{ kg/kmol}}{30.80 \text{ kg/kmol}} = \mathbf{0.6364} \end{aligned}$$

The final pressure of mixture is expressed from ideal gas relation to be

$$P_2 = P_1 r \frac{T_2}{T_1} = (100 \text{ kPa})(8) \frac{T_2}{300 \text{ K}} = 2.667 T_2 \quad (\text{Eq. 1})$$

since the final temperature is not known. We assume that the process is reversible as well being adiabatic (i.e. isentropic). Using Dalton's law to find partial pressures, the entropies at the initial state are determined from EES to be:

$$T = 300 \text{ K}, P = (0.2143 \times 100) = 21.43 \text{ kPa} \longrightarrow s_{\text{CO}_2,1} = 5.2190 \text{ kJ/kg.K}$$

$$T = 300 \text{ K}, P = (0.04545 \times 100) = 4.55 \text{ kPa} \longrightarrow s_{\text{CO},1} = 7.9483 \text{ kJ/kg.K}$$

$$T = 300 \text{ K}, P = (0.1039 \times 100) = 10.39 \text{ kPa} \longrightarrow s_{\text{N}_2,1} = 6.9485 \text{ kJ/kg.K}$$

$$T = 300 \text{ K}, P = (0.6364 \times 100) = 63.64 \text{ kPa} \longrightarrow s_{\text{O}_2,1} = 7.0115 \text{ kJ/kg.K}$$

The final state entropies cannot be determined at this point since the final pressure and temperature are not known. However, for an isentropic process, the entropy change is zero and the final temperature and the final pressure may be determined from

$$\Delta s_{\text{total}} = \text{mf}_{\text{CO}_2} \Delta s_{\text{CO}_2} + \text{mf}_{\text{CO}} \Delta s_{\text{CO}} + \text{mf}_{\text{O}_2} \Delta s_{\text{O}_2} + \text{mf}_{\text{N}_2} \Delta s_{\text{N}_2} = 0$$

and using Eq. (1). The solution may be obtained using EES to be  $T_2 = 631.4 \text{ K}$ ,  $P_2 = 1684 \text{ kPa}$

The initial and final internal energies are (from EES)

$$\begin{aligned}
 &u_{\text{CO}_2,1} = -8997 \text{ kJ/kg} \\
 T_1 = 300 \text{ K} \longrightarrow &u_{\text{CC},1} = -4033 \text{ kJ/kg} \\
 &u_{\text{O}_2,1} = -76.24 \text{ kJ/kg} \\
 &u_{\text{N}_2,1} = -87.11 \text{ kJ/kg},
 \end{aligned}$$

$$\begin{aligned}
 &u_{\text{CO}_2,2} = -8734 \text{ kJ/kg} \\
 T_2 = 631.4 \text{ K} \longrightarrow &u_{\text{CO},2} = -3780 \text{ kJ/kg} \\
 &u_{\text{O}_2,2} = 156.8 \text{ kJ/kg} \\
 &u_{\text{N}_2,2} = 163.9 \text{ kJ/kg}
 \end{aligned}$$

The internal energy change per unit mass of mixture is determined from

$$\begin{aligned}
 \Delta u_{\text{mixture}} &= \text{mf}_{\text{CO}_2} (u_{\text{CO}_2,2} - u_{\text{CO}_2,1}) + \text{mf}_{\text{CO}} (u_{\text{CO},2} - u_{\text{CO},1}) + \text{mf}_{\text{O}_2} (u_{\text{O}_2,2} - u_{\text{O}_2,1}) + \text{mf}_{\text{N}_2} (u_{\text{N}_2,2} - u_{\text{N}_2,1}) \\
 &= 0.2143[-8734 - (-8997)] + 0.0454[-3780 - (-4033)] \\
 &\quad + 0.1039[156.8 - (-76.24)] + 0.6364[163.9 - (-87.11)] \\
 &= \mathbf{251.8 \text{ kJ/kg}}
 \end{aligned}$$

**13-56** Propane and air mixture is compressed isentropically in an internal combustion engine. The work input is to be determined.

**Assumptions** Under specified conditions propane and air can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Properties** The molar masses of  $C_3H_8$  and air are 44.0 and 28.97 kg/kmol, respectively (Table A-1).

**Analysis** Given the air-fuel ratio, the mass fractions are determined to be

$$mf_{\text{air}} = \frac{AF}{AF+1} = \frac{16}{17} = 0.9412$$

$$mf_{C_3H_8} = \frac{1}{AF+1} = \frac{1}{17} = 0.05882$$

The molar mass of the mixture is determined to be

$$M_m = \frac{1}{\frac{mf_{\text{air}}}{M_{\text{air}}} + \frac{mf_{C_3H_8}}{M_{C_3H_8}}} = \frac{1}{\frac{0.9412}{28.97 \text{ kg/kmol}} + \frac{0.05882}{44.0 \text{ kg/kmol}}} = 29.56 \text{ kg/kmol}$$

The mole fractions are

$$y_{\text{air}} = mf_{\text{air}} \frac{M_m}{M_{\text{air}}} = (0.9412) \frac{29.56 \text{ kg/kmol}}{28.97 \text{ kg/kmol}} = 0.9606$$

$$y_{C_3H_8} = mf_{C_3H_8} \frac{M_m}{M_{C_3H_8}} = (0.05882) \frac{29.56 \text{ kg/kmol}}{44.0 \text{ kg/kmol}} = 0.03944$$

The final pressure is expressed from ideal gas relation to be

$$P_2 = P_1 r \frac{T_2}{T_1} = (95 \text{ kPa})(9.5) \frac{T_2}{(30 + 273.15) \text{ K}} = 2.977 T_2 \quad (1)$$

since the final temperature is not known. Using Dalton's law to find partial pressures, the entropies at the initial state are determined from EES to be:

$$T = 30^\circ\text{C}, P = (0.9606 \times 95) = 91.26 \text{ kPa} \longrightarrow s_{\text{air},1} = 5.7417 \text{ kJ/kg}\cdot\text{K}$$

$$T = 30^\circ\text{C}, P = (0.03944 \times 95) = 3.75 \text{ kPa} \longrightarrow s_{C_3H_8,1} = 6.7697 \text{ kJ/kg}\cdot\text{K}$$

The final state entropies cannot be determined at this point since the final pressure and temperature are not known. However, for an isentropic process, the entropy change is zero and the final temperature and the final pressure may be determined from

$$\Delta s_{\text{total}} = mf_{\text{air}} \Delta s_{\text{air}} + mf_{C_3H_8} \Delta s_{C_3H_8} = 0$$

and using Eq. (1). The solution may be obtained using EES to be

$$T_2 = 654.9 \text{ K}, P_2 = 1951 \text{ kPa}$$

The initial and final internal energies are (from EES)

$$T_1 = 30^\circ\text{C} \longrightarrow \begin{array}{l} u_{\text{air},1} = 216.5 \text{ kJ/kg} \\ u_{C_3H_8,1} = -2404 \text{ kJ/kg} \end{array} \quad T_2 = 654.9 \text{ K} \longrightarrow \begin{array}{l} u_{\text{air},2} = 477.1 \text{ kJ/kg} \\ u_{C_3H_8,2} = -1607 \text{ kJ/kg} \end{array}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$q_{\text{in}} + w_{\text{in}} = \Delta u_m \longrightarrow w_{\text{in}} = \Delta u_m$$

$$\text{where } \Delta u_m = mf_{\text{air}} (u_{\text{air},2} - u_{\text{air},1}) + mf_{C_3H_8} (u_{C_3H_8,2} - u_{C_3H_8,1})$$

$$\text{Substituting, } w_{\text{in}} = \Delta u_m = (0.9412)(477.1 - 216.5) + (0.05882)[(-1607) - (-2404)] = \mathbf{292.2 \text{ kJ/kg}}$$

**13-57** The moles, temperatures, and pressures of two gases forming a mixture are given. The mixture temperature and pressure are to be determined.

**Assumptions 1** Under specified conditions both CO<sub>2</sub> and H<sub>2</sub> can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** The tank is insulated and thus there is no heat transfer. **3** There are no other forms of work involved.

**Properties** The molar masses and specific heats of CO<sub>2</sub> and H<sub>2</sub> are 44.0 kg/kmol, 2.0 kg/kmol, 0.657 kJ/kg·°C, and 10.183 kJ/kg·°C, respectively. (Tables A-1 and A-2b).

**Analysis (a)** We take both gases as our system. No heat, work, or mass crosses the system boundary, therefore this is a closed system with  $Q = 0$  and  $W = 0$ . Then the energy balance for this closed system reduces to

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ 0 &= \Delta U = \Delta U_{\text{CO}_2} + \Delta U_{\text{H}_2} \\ 0 &= [mc_v(T_m - T_1)]_{\text{CO}_2} + [mc_v(T_m - T_1)]_{\text{H}_2} \end{aligned}$$

Using  $c_v$  values at room temperature and noting that  $m = NM$ , the final temperature of the mixture is determined to be

$$\begin{aligned} (2.5 \times 44 \text{ kg})(0.657 \text{ kJ/kg} \cdot ^\circ\text{C})(T_m - 27^\circ\text{C}) + (7.5 \times 2 \text{ kg})(10.183 \text{ kJ/kg} \cdot ^\circ\text{C})(T_m - 40^\circ\text{C}) &= 0 \\ T_m &= \mathbf{35.8^\circ\text{C}} \quad (308.8 \text{ K}) \end{aligned}$$

| CO <sub>2</sub> | H <sub>2</sub> |
|-----------------|----------------|
| 2.5 kmol        | 7.5 kmol       |
| 200 kPa         | 400 kPa        |
| 27°C            | 40°C           |

(b) The volume of each tank is determined from

$$\begin{aligned} \nu_{\text{CO}_2} &= \left( \frac{NR_u T_1}{P_1} \right)_{\text{CO}_2} = \frac{(2.5 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(300 \text{ K})}{200 \text{ kPa}} = 31.18 \text{ m}^3 \\ \nu_{\text{H}_2} &= \left( \frac{NR_u T_1}{P_1} \right)_{\text{H}_2} = \frac{(7.5 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(313 \text{ K})}{400 \text{ kPa}} = 48.79 \text{ m}^3 \end{aligned}$$

Thus,

$$\begin{aligned} \nu_m &= \nu_{\text{CO}_2} + \nu_{\text{H}_2} = 31.18 \text{ m}^3 + 48.79 \text{ m}^3 = 79.97 \text{ m}^3 \\ N_m &= N_{\text{CO}_2} + N_{\text{H}_2} = 2.5 \text{ kmol} + 7.5 \text{ kmol} = 10.0 \text{ kmol} \end{aligned}$$

and

$$P_m = \frac{N_m R_u T_m}{\nu_m} = \frac{(10.0 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(308.8 \text{ K})}{79.97 \text{ m}^3} = \mathbf{321 \text{ kPa}}$$

**13-58 [Also solved by EES on enclosed CD]** The temperatures and pressures of two gases forming a mixture in a mixing chamber are given. The mixture temperature and the rate of entropy generation are to be determined.

**Assumptions** 1 Under specified conditions both  $\text{C}_2\text{H}_6$  and  $\text{CH}_4$  can be treated as ideal gases, and the mixture as an ideal gas mixture. 2 The mixing chamber is insulated and thus there is no heat transfer. 3 There are no other forms of work involved. 4 This is a steady-flow process. 5 The kinetic and potential energy changes are negligible.

**Properties** The specific heats of  $\text{C}_2\text{H}_6$  and  $\text{CH}_4$  are 1.7662 kJ/kg·°C and 2.2537 kJ/kg·°C, respectively. (Table A-2b).

**Analysis** (a) The enthalpy of ideal gases is independent of pressure, and thus the two gases can be treated independently even after mixing. Noting that  $\dot{W} = \dot{Q} = 0$ , the steady-flow energy balance equation reduces to

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi=0 \text{ (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i = \dot{m}_{\text{C}_2\text{H}_6} (h_e - h_i)_{\text{C}_2\text{H}_6} + \dot{m}_{\text{CH}_4} (h_e - h_i)_{\text{CH}_4} \\ 0 &= [\dot{m} c_p (T_e - T_i)]_{\text{C}_2\text{H}_6} + [\dot{m} c_p (T_e - T_i)]_{\text{CH}_4}\end{aligned}$$

Using  $c_p$  values at room temperature and substituting, the exit temperature of the mixture becomes

$$\begin{aligned}0 &= (9 \text{ kg/s})(1.7662 \text{ kJ/kg} \cdot ^\circ\text{C})(T_m - 20^\circ\text{C}) + (4.5 \text{ kg/s})(2.2537 \text{ kJ/kg} \cdot ^\circ\text{C})(T_m - 45^\circ\text{C}) \\ T_m &= 29.7^\circ\text{C} \quad (302.7 \text{ K})\end{aligned}$$

(b) The rate of entropy change associated with this process is determined from an entropy balance on the mixing chamber,

$$\begin{aligned}\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} &= \Delta \dot{S}_{\text{system}} \stackrel{\pi=0}{=} 0 \\ [\dot{m}(s_1 - s_2)]_{\text{C}_2\text{H}_6} + [\dot{m}(s_1 - s_2)]_{\text{CH}_4} + \dot{S}_{\text{gen}} &= 0 \\ \dot{S}_{\text{gen}} &= [\dot{m}(s_2 - s_1)]_{\text{C}_2\text{H}_6} + [\dot{m}(s_2 - s_1)]_{\text{CH}_4}\end{aligned}$$

The molar flow rate of the two gases in the mixture is

$$\begin{aligned}\dot{N}_{\text{C}_2\text{H}_6} &= \left( \frac{\dot{m}}{M} \right)_{\text{C}_2\text{H}_6} = \frac{9 \text{ kg/s}}{30 \text{ kg/kmol}} = 0.3 \text{ kmol/s} \\ \dot{N}_{\text{CH}_4} &= \left( \frac{\dot{m}}{M} \right)_{\text{CH}_4} = \frac{4.5 \text{ kg/s}}{16 \text{ kg/kmol}} = 0.2813 \text{ kmol/s}\end{aligned}$$

Then the mole fraction of each gas becomes

$$\begin{aligned}y_{\text{C}_2\text{H}_6} &= \frac{0.3}{0.3 + 0.2813} = 0.516 \\ y_{\text{CH}_4} &= \frac{0.2813}{0.3 + 0.2813} = 0.484\end{aligned}$$

Thus,

$$\begin{aligned}
 (s_2 - s_1)_{\text{C}_2\text{H}_6} &= \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{\text{C}_2\text{H}_6} = \left( c_p \ln \frac{T_2}{T_1} - R \ln y \right)_{\text{C}_2\text{H}_6} \\
 &= (1.7662 \text{ kJ/kg} \cdot \text{K}) \ln \frac{302.7 \text{ K}}{293 \text{ K}} - (0.2765 \text{ kJ/kg} \cdot \text{K}) \ln(0.516) = 0.240 \text{ kJ/kg} \cdot \text{K}
 \end{aligned}$$

$$\begin{aligned}
 (s_2 - s_1)_{\text{CH}_4} &= \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{\text{CH}_4} = \left( c_p \ln \frac{T_2}{T_1} - R \ln y \right)_{\text{CH}_4} \\
 &= (2.2537 \text{ kJ/kg} \cdot \text{K}) \ln \frac{302.7 \text{ K}}{318 \text{ K}} - (0.5182 \text{ kJ/kg} \cdot \text{K}) \ln(0.484) = 0.265 \text{ kJ/kg} \cdot \text{K}
 \end{aligned}$$

Noting that  $P_{m,2} = P_{i,1} = 200 \text{ kPa}$  and substituting,

$$\dot{S}_{\text{gen}} = (9 \text{ kg/s})(0.240 \text{ kJ/kg} \cdot \text{K}) + (4.5 \text{ kg/s})(0.265 \text{ kJ/kg} \cdot \text{K}) = \mathbf{3.353 \text{ kW/K}}$$

**13-59 EES** Problem 13-58 is reconsidered. The effect of the mass fraction of methane in the mixture on the mixture temperature and the rate of exergy destruction is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

"Input from the Diagram Window"

{Fluid1\$='C2H6'

Fluid2\$='CH4'

**13-60** A mixture of hydrogen and oxygen is considered. The entropy change of this mixture between the two specified states is to be determined.

**Assumptions** Hydrogen and oxygen are ideal gases.

**Properties** The gas constants of hydrogen and oxygen are 4.124 and 0.2598 kJ/kg·K, respectively (Table A-1).

**Analysis** The effective gas constant of this mixture is

$R = m_{f_{H_2}} R_{H_2} + m_{f_{O_2}} R_{O_2} = (0.33)(4.1240) + (0.67)(0.2598) = 1.5350 \text{ kJ/kg} \cdot \text{K}$  Since the temperature of the two states is the same, the entropy change is determined from

$$s_2 - s_1 = -R \ln \frac{P_2}{P_1} = -(1.5350 \text{ kJ/kg} \cdot \text{K}) \ln \frac{150 \text{ kPa}}{750 \text{ kPa}} = \mathbf{2.470 \text{ kJ/kg} \cdot \text{K}}$$

**13-61** A mixture of nitrogen and carbon dioxide is heated at constant pressure in a closed system. The work produced is to be determined.

**Assumptions** 1 Nitrogen and carbon dioxide are ideal gases. 2 The process is reversible.

**Properties** The mole numbers of nitrogen and carbon dioxide are 28.0 and 44.0 kg/kmol, respectively (Table A-1).

**Analysis** One kg of this mixture consists of 0.5 kg of nitrogen and 0.5 kg of carbon dioxide or  $0.5 \text{ kg} \times 28.0 \text{ kg/kmol} = 14.0 \text{ kmol}$  of nitrogen and  $0.5 \text{ kg} \times 44.0 \text{ kg/kmol} = 22.0 \text{ kmol}$  of carbon dioxide. The constituent mole fraction are then

$$y_{N_2} = \frac{N_{N_2}}{N_{\text{total}}} = \frac{14 \text{ kmol}}{36 \text{ kmol}} = 0.3889$$

$$y_{CO_2} = \frac{N_{CO_2}}{N_{\text{total}}} = \frac{22 \text{ kmol}}{36 \text{ kmol}} = 0.6111$$

The effective molecular weight of this mixture is

$$\begin{aligned} M &= y_{N_2} M_{N_2} + y_{CO_2} M_{CO_2} \\ &= (0.3889)(28) + (0.6111)(44) = 37.78 \text{ kg/kmol} \end{aligned}$$

The work done is determined from

$$\begin{aligned} w &= \int_1^2 P dV = P_2 v_2 - P_1 v_1 = R(T_2 - T_1) \\ &= \frac{R_u}{M} (T_2 - T_1) = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{37.78 \text{ kg/kmol}} (200 - 30) \text{ K} \\ &= \mathbf{37.4 \text{ kJ/kg}} \end{aligned}$$

**13-62E** The mass fractions of components of a gas mixture are given. This mixture is compressed in an isentropic process. The final mixture temperature and the work required per unit mass of the mixture are to be determined.

**Assumptions** All gases will be modeled as ideal gases with constant specific heats.

**Properties** The molar masses of  $N_2$ , He,  $CH_4$ , and  $C_2H_6$  are 28.0, 4.0, 16.0, and 30.0 lbm/lbmol, respectively (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.248, 1.25, 0.532, and 0.427 Btu/lbm·R, respectively (Table A-2Ea).

**Analysis** We consider 100 lbm of this mixture. The mole numbers of each component are

$$\begin{aligned} N_{N_2} &= \frac{m_{N_2}}{M_{N_2}} = \frac{15 \text{ lbm}}{28 \text{ lbm/lbmol}} = 0.5357 \text{ lbmol} \\ N_{He} &= \frac{m_{He}}{M_{He}} = \frac{5 \text{ lbm}}{4 \text{ lbm/lbmol}} = 1.25 \text{ lbmol} \\ N_{CH_4} &= \frac{m_{CH_4}}{M_{CH_4}} = \frac{60 \text{ lbm}}{16 \text{ lbm/lbmol}} = 3.75 \text{ lbmol} \\ N_{C_2H_6} &= \frac{m_{C_2H_6}}{M_{C_2H_6}} = \frac{20 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.6667 \text{ lbmol} \end{aligned}$$

15%  $N_2$   
5% He  
60%  $CH_4$   
20%  $C_2H_6$   
(by mass)  
  
20 psia, 100°F

The mole number of the mixture is

$$N_m = N_{N_2} + N_{He} + N_{CH_4} + N_{C_2H_6} = 0.5357 + 1.25 + 3.75 + 0.6667 = 6.2024 \text{ lbmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{6.2024 \text{ lbmol}} = 16.12 \text{ lbm/lbmol}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{He} c_{p,He} + mf_{CH_4} c_{p,CH_4} + mf_{C_2H_6} c_{p,C_2H_6} \\ &= 0.15 \times 0.248 + 0.05 \times 1.25 + 0.60 \times 0.532 + 0.20 \times 0.427 \\ &= 0.5043 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{16.12 \text{ lbm/lbmol}} = 0.1232 \text{ Btu/lbm} \cdot \text{R}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 0.5043 - 0.1232 = 0.3811 \text{ Btu/lbm} \cdot \text{R}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{0.5043}{0.3811} = 1.323$$

The temperature at the end of the compression is

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (560 \text{ R}) \left( \frac{200 \text{ psia}}{20 \text{ psia}} \right)^{0.323/1.323} = \mathbf{982 \text{ R}}$$

An energy balance on the adiabatic compression process gives

$$w_{in} = c_p (T_2 - T_1) = (0.5043 \text{ Btu/lbm} \cdot \text{R})(982 - 560) \text{ R} = \mathbf{213 \text{ Btu/lbm}}$$

**13-63** The mass fractions of components of a gas mixture are given. This mixture is compressed in a reversible, isothermal, steady-flow compressor. The work and heat transfer for this compression per unit mass of the mixture are to be determined.

**Assumptions** All gases will be modeled as ideal gases with constant specific heats.

**Properties** The molar masses of  $\text{CH}_4$ ,  $\text{C}_3\text{H}_8$ , and  $\text{C}_4\text{H}_{10}$  are 16.0, 44.0, and 58.0 lbm/lbmol, respectively (Table A-1E).

**Analysis** The mole numbers of each component are

$$\begin{aligned} N_{\text{CH}_4} &= \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ lbm}}{16 \text{ lbm/lbmol}} = 3.75 \text{ lbmol} \\ N_{\text{C}_3\text{H}_8} &= \frac{m_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}} = \frac{25 \text{ lbm}}{44 \text{ lbm/lbmol}} = 0.5682 \text{ lbmol} \\ N_{\text{C}_4\text{H}_{10}} &= \frac{m_{\text{C}_4\text{H}_{10}}}{M_{\text{C}_4\text{H}_{10}}} = \frac{15 \text{ lbm}}{58 \text{ lbm/lbmol}} = 0.2586 \text{ lbmol} \end{aligned}$$

The mole number of the mixture is

$$\begin{aligned} N_m &= N_{\text{CH}_4} + N_{\text{C}_3\text{H}_8} + N_{\text{C}_4\text{H}_{10}} \\ &= 3.75 + 0.5682 + 0.2586 = 4.5768 \text{ lbmol} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{4.5768 \text{ lbmol}} = 21.85 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{21.85 \text{ kg/kmol}} = 0.3805 \text{ kJ/kg} \cdot \text{K}$$

For a reversible, isothermal process, the work input is

$$w_{\text{in}} = RT \ln \left( \frac{P_2}{P_1} \right) = (0.3805 \text{ kJ/kg} \cdot \text{K})(293 \text{ K}) \ln \left( \frac{1000 \text{ kPa}}{100 \text{ kPa}} \right) = \mathbf{257 \text{ kJ/kg}}$$

An energy balance on the control volume gives

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \overset{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 + \dot{W}_{\text{in}} = \dot{m}h_2 + \dot{Q}_{\text{out}}$$

$$\dot{W}_{\text{in}} - \dot{Q}_{\text{out}} = \dot{m}(h_2 - h_1)$$

$$w_{\text{in}} - q_{\text{out}} = c_p(T_2 - T_1) = 0 \quad \text{since } T_2 = T_1$$

$$w_{\text{in}} = q_{\text{out}}$$

That is,

$$q_{\text{out}} = w_{\text{in}} = \mathbf{257 \text{ kJ/kg}}$$

**13-64** The masses of components of a gas mixture are given. This mixture is heated at constant pressure. The change in the volume of the mixture and the total heat transferred to the mixture are to be determined.

**Assumptions** All gases will be modeled as ideal gases with constant specific heats.

**Properties** The molar masses of O<sub>2</sub>, CO<sub>2</sub>, and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 0.918, 0.846, and 5.1926 kJ/kg·K, respectively (Table A-2a).

**Analysis** The total mass of the mixture is

$$m_m = m_{\text{O}_2} + m_{\text{CO}_2} + m_{\text{He}} = 0.1 + 1 + 0.5 = 1.6 \text{ kg}$$

The mole numbers of each component are

$$\begin{aligned} N_{\text{O}_2} &= \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.1 \text{ kg}}{32 \text{ kg/kmol}} = 0.003125 \text{ kmol} \\ N_{\text{CO}_2} &= \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.02273 \text{ kmol} \\ N_{\text{He}} &= \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{0.5 \text{ kg}}{4 \text{ kg/kmol}} = 0.125 \text{ kmol} \end{aligned}$$

0.1 kg O<sub>2</sub>  
1 kg CO<sub>2</sub>  
0.5 kg He  
  
350 kPa, 10°C

The mole number of the mixture is

$$N_m = N_{\text{O}_2} + N_{\text{CO}_2} + N_{\text{He}} = 0.003125 + 0.02273 + 0.125 = 0.15086 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1.6 \text{ kg}}{0.15086 \text{ kmol}} = 10.61 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{10.61 \text{ kg/kmol}} = 0.7836 \text{ kJ/kg} \cdot \text{K}$$

The mass fractions are

$$\begin{aligned} \text{mf}_{\text{O}_2} &= \frac{m_{\text{O}_2}}{m_m} = \frac{0.1 \text{ kg}}{1.6 \text{ kg}} = 0.0625 \\ \text{mf}_{\text{CO}_2} &= \frac{m_{\text{CO}_2}}{m_m} = \frac{1 \text{ kg}}{1.6 \text{ kg}} = 0.625 \\ \text{mf}_{\text{He}} &= \frac{m_{\text{He}}}{m_m} = \frac{0.5 \text{ kg}}{1.6 \text{ kg}} = 0.3125 \end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= \text{mf}_{\text{O}_2} c_{p,\text{O}_2} + \text{mf}_{\text{CO}_2} c_{p,\text{CO}_2} + \text{mf}_{\text{He}} c_{p,\text{He}} \\ &= 0.0625 \times 0.918 + 0.625 \times 0.846 + 0.3125 \times 5.1926 \\ &= 2.209 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The change in the volume of this ideal gas mixture is

$$\Delta V_m = \frac{m_m R \Delta T}{P} = \frac{(1.6 \text{ kg})(0.7836 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(260 - 10) \text{ K}}{350 \text{ kPa}} = \mathbf{0.8955 \text{ m}^3}$$

The heat transfer is determined to be

$$q_{\text{in}} = c_p (T_2 - T_1) = (2.209 \text{ kJ/kg} \cdot \text{K})(260 - 10) \text{ K} = \mathbf{552 \text{ kJ/kg}}$$

**13-65E** The volume fractions of components of a gas mixture during the expansion process of the ideal Otto cycle are given. The thermal efficiency of this cycle is to be determined.

**Assumptions** All gases will be modeled as ideal gases with constant specific heats.

**Properties** The molar masses of  $N_2$ ,  $O_2$ ,  $H_2O$ , and  $CO_2$  are 28.0, 32.0, 18.0, and 44.0 lbm/lbmol, respectively (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.248, 0.219, 0.445, and 0.203 Btu/lbm·R, respectively. The air properties at room temperature are  $c_p = 0.240$  Btu/lbm·R,  $c_v = 0.171$  Btu/lbm·R,  $k = 1.4$  (Table A-2Ea).

**Analysis** We consider 100 lbmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$m_{N_2} = N_{N_2} M_{N_2} = (25 \text{ lbmol})(28 \text{ lbm/lbmol}) = 700 \text{ lbm}$$

$$m_{O_2} = N_{O_2} M_{O_2} = (7 \text{ lbmol})(32 \text{ lbm/lbmol}) = 224 \text{ lbm}$$

$$m_{H_2O} = N_{H_2O} M_{H_2O} = (28 \text{ lbmol})(18 \text{ lbm/lbmol}) = 504 \text{ lbm}$$

$$m_{CO_2} = N_{CO_2} M_{CO_2} = (40 \text{ lbmol})(44 \text{ lbm/lbmol}) = 1760 \text{ lbm}$$

The total mass is

$$\begin{aligned} m_m &= m_{N_2} + m_{O_2} + m_{H_2O} + m_{CO_2} \\ &= 700 + 224 + 504 + 1760 \\ &= 3188 \text{ lbm} \end{aligned}$$

Then the mass fractions are

$$mf_{N_2} = \frac{m_{N_2}}{m_m} = \frac{700 \text{ lbm}}{3188 \text{ lbm}} = 0.2196$$

$$mf_{O_2} = \frac{m_{O_2}}{m_m} = \frac{224 \text{ lbm}}{3188 \text{ lbm}} = 0.07026$$

$$mf_{H_2O} = \frac{m_{H_2O}}{m_m} = \frac{504 \text{ lbm}}{3188 \text{ lbm}} = 0.1581$$

$$mf_{CO_2} = \frac{m_{CO_2}}{m_m} = \frac{1760 \text{ lbm}}{3188 \text{ lbm}} = 0.5521$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{O_2} c_{p,O_2} + mf_{H_2O} c_{p,H_2O} + mf_{CO_2} c_{p,CO_2} \\ &= 0.2196 \times 0.248 + 0.07026 \times 0.219 + 0.1581 \times 0.445 + 0.5521 \times 0.203 \\ &= 0.2523 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{3188 \text{ lbm}}{100 \text{ lbmol}} = 31.88 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{31.88 \text{ lbm/lbmol}} = 0.06229 \text{ Btu/lbm} \cdot \text{R}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 0.2523 - 0.06229 = 0.1900 \text{ Btu/lbm} \cdot \text{R}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{0.2523}{0.1900} = 1.328$$

The average of the air properties at room temperature and combustion gas properties are

$$c_{p,\text{avg}} = 0.5(0.2523 + 0.240) = 0.2462 \text{ Btu/lbm} \cdot \text{R}$$

$$c_{v,\text{avg}} = 0.5(0.1900 + 0.171) = 0.1805 \text{ Btu/lbm} \cdot \text{R}$$

$$k_{\text{avg}} = 0.5(1.328 + 1.4) = 1.364$$

These average properties will be used for heat addition and rejection processes. For compression, the air properties at room temperature and during expansion, the mixture properties will be used. During the compression process,

$$T_2 = T_1 r^{k-1} = (515 \text{ R})(7)^{0.4} = 1122 \text{ R}$$

During the heat addition process,

$$q_{\text{in}} = c_{v,\text{avg}}(T_3 - T_2) = (0.1805 \text{ Btu/lbm} \cdot \text{R})(2060 - 1122) \text{ R} = 169.3 \text{ Btu/lbm}$$

During the expansion process,

$$T_4 = T_3 \left( \frac{1}{r} \right)^{k-1} = (2060 \text{ R}) \left( \frac{1}{7} \right)^{0.364} = 1014 \text{ R}$$

During the heat rejection process,

$$q_{\text{out}} = c_{v,\text{avg}}(T_4 - T_1) = (0.1805 \text{ Btu/lbm} \cdot \text{R})(1014 - 515) \text{ R} = 90.1 \text{ Btu/lbm}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{90.1 \text{ Btu/lbm}}{169.3 \text{ Btu/lbm}} = \mathbf{0.468}$$

**13-66E** The thermal efficiency of the cycle in the previous problem is to be compared to that predicted by air standard analysis?

**Assumptions** Air-standard assumptions are applicable.

**Properties** The air properties at room temperature are  $c_p = 0.240$  Btu/lbm·R,  $c_v = 0.171$  Btu/lbm·R,  $k = 1.4$  (Table A-2Ea).

**Analysis** In the previous problem, the thermal efficiency of the cycle was determined to be **0.468** (46.8%). The thermal efficiency with air-standard model is determined from

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{7^{0.4}} = \mathbf{0.541}$$

which is significantly greater than that calculated with gas mixture analysis in the previous problem.

**13-67** The volume fractions of components of a gas mixture passing through the turbine of a simple ideal Brayton cycle are given. The thermal efficiency of this cycle is to be determined.

**Assumptions** All gases will be modeled as ideal gases with constant specific heats.

**Properties** The molar masses of  $N_2$ ,  $O_2$ ,  $H_2O$ , and  $CO_2$  are 28.0, 32.0, 18.0, and 44.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 1.039, 0.918, 1.8723, and 0.846 kJ/kg·K, respectively. The air properties at room temperature are  $c_p = 1.005$  kJ/kg·K,  $c_v = 0.718$  kJ/kg·K,  $k = 1.4$  (Table A-2a).

**Analysis** We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{N_2} &= N_{N_2} M_{N_2} = (30 \text{ kmol})(28 \text{ kg/kmol}) = 840 \text{ kg} \\ m_{O_2} &= N_{O_2} M_{O_2} = (10 \text{ kmol})(32 \text{ kg/kmol}) = 320 \text{ kg} \\ m_{H_2O} &= N_{H_2O} M_{H_2O} = (20 \text{ kmol})(18 \text{ kg/kmol}) = 360 \text{ kg} \\ m_{CO_2} &= N_{CO_2} M_{CO_2} = (40 \text{ kmol})(44 \text{ kg/kmol}) = 1760 \text{ kg} \end{aligned}$$

The total mass is

$$\begin{aligned} m_m &= m_{N_2} + m_{O_2} + m_{H_2O} + m_{CO_2} \\ &= 840 + 320 + 360 + 1760 \\ &= 3280 \text{ kg} \end{aligned}$$

Then the mass fractions are

$$\begin{aligned} mf_{N_2} &= \frac{m_{N_2}}{m_m} = \frac{840 \text{ kg}}{3280 \text{ kg}} = 0.2561 \\ mf_{O_2} &= \frac{m_{O_2}}{m_m} = \frac{320 \text{ kg}}{3280 \text{ kg}} = 0.09756 \\ mf_{H_2O} &= \frac{m_{H_2O}}{m_m} = \frac{360 \text{ kg}}{3280 \text{ kg}} = 0.1098 \\ mf_{CO_2} &= \frac{m_{CO_2}}{m_m} = \frac{1760 \text{ kg}}{3280 \text{ kg}} = 0.5366 \end{aligned}$$

30%  $N_2$ , 10%  $O_2$   
20%  $H_2O$ , 40%  $CO_2$   
(by volume)

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{O_2} c_{p,O_2} + mf_{H_2O} c_{p,H_2O} + mf_{CO_2} c_{p,CO_2} \\ &= 0.2561 \times 1.039 + 0.09756 \times 0.918 + 0.1098 \times 1.8723 + 0.5366 \times 0.846 \\ &= 1.015 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{3280 \text{ kg}}{100 \text{ kmol}} = 32.80 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{32.80 \text{ kg/kmol}} = 0.2535 \text{ kJ/kg} \cdot \text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 1.015 - 0.2535 = 0.762 \text{ kJ/kg} \cdot \text{K}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{1.015}{0.762} = 1.332$$

The average of the air properties at room temperature and combustion gas properties are

$$c_{p,\text{avg}} = 0.5(1.015 + 1.005) = 1.010 \text{ kJ/kg} \cdot \text{K}$$

$$c_{v,\text{avg}} = 0.5(0.762 + 0.718) = 0.740 \text{ kJ/kg} \cdot \text{K}$$

$$k_{\text{avg}} = 0.5(1.332 + 1.4) = 1.366$$

These average properties will be used for heat addition and rejection processes. For compression, the air properties at room temperature and during expansion, the mixture properties will be used. During the compression process,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (293 \text{ K})(8)^{0.4/1.4} = 531 \text{ K}$$

During the heat addition process,

$$q_{\text{in}} = c_{p,\text{avg}}(T_3 - T_2) = (1.010 \text{ kJ/kg} \cdot \text{K})(1273 - 531) \text{ K} = 749.4 \text{ kJ/kg}$$

During the expansion process,

$$T_4 = T_3 \left( \frac{P_4}{P_3} \right)^{(k-1)/k} = (1273 \text{ K}) \left( \frac{1}{8} \right)^{0.332/1.332} = 758 \text{ K}$$

During the heat rejection process,

$$q_{\text{out}} = c_{p,\text{avg}}(T_4 - T_1) = (1.010 \text{ kJ/kg} \cdot \text{K})(758 - 293) \text{ K} = 469.7 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{469.7 \text{ kJ/kg}}{749.4 \text{ kJ/kg}} = \mathbf{0.373}$$

**13-68** The thermal efficiency of the cycle in the previous problem is to be compared to that predicted by air standard analysis?

**Assumptions** Air-standard assumptions are applicable.

**Properties** The air properties at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ ,  $c_v = 1.4 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 1.4$  (Table A-2a).

**Analysis** In the previous problem, the thermal efficiency of the cycle was determined to be **0.373** (37.3%). The thermal efficiency with air-standard model is determined from

$$\eta_{\text{th}} = 1 - \frac{1}{r_p^{(k-1)/k}} = 1 - \frac{1}{8^{0.4/1.4}} = \mathbf{0.448}$$

which is significantly greater than that calculated with gas mixture analysis in the previous problem.

**13-69E** The mass fractions of a natural gas mixture at a specified pressure and temperature trapped in a geological location are given. This natural gas is pumped to the surface. The work required is to be determined using Kay's rule and the enthalpy-departure method.

**Properties** The molar masses of  $\text{CH}_4$  and  $\text{C}_2\text{H}_6$  are 16.0 and 30.0 lbm/lbmol, respectively. The critical properties are 343.9 R, 673 psia for  $\text{CH}_4$  and 549.8 R and 708 psia for  $\text{C}_2\text{H}_6$  (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.532 and 0.427 Btu/lbm·R, respectively (Table A-2Ea).

**Analysis** We consider 100 lbm of this mixture. Then the mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ lbm}}{16 \text{ lbm/lbmol}} = 4.6875 \text{ lbmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{25 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.8333 \text{ lbmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 4.6875 + 0.8333 = 5.5208 \text{ lbmol}$$

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.6875 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.8491$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{0.8333 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.1509$$

75%  $\text{CH}_4$   
25%  $\text{C}_2\text{H}_6$   
(by mass)  
2000 psia  
300°F

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{5.5208 \text{ lbmol}} = 18.11 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{18.11 \text{ lbm/lbmol}} = 0.1097 \text{ Btu/lbm} \cdot \text{R}$$

The constant-pressure specific heat of the mixture is determined from

$$c_p = \text{mf}_{\text{CH}_4} c_{p,\text{CH}_4} + \text{mf}_{\text{C}_2\text{H}_6} c_{p,\text{C}_2\text{H}_6} = 0.75 \times 0.532 + 0.25 \times 0.427 = 0.506 \text{ Btu/lbm} \cdot \text{R}$$

To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{CH}_4} T_{\text{cr},\text{CH}_4} + y_{\text{C}_2\text{H}_6} T_{\text{cr},\text{C}_2\text{H}_6} \\ &= (0.8491)(343.9 \text{ R}) + (0.1509)(549.8 \text{ R}) = 375.0 \text{ R} \end{aligned}$$

$$\begin{aligned} P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{CH}_4} P_{\text{cr},\text{CH}_4} + y_{\text{C}_2\text{H}_6} P_{\text{cr},\text{C}_2\text{H}_6} \\ &= (0.8491)(673 \text{ psia}) + (0.1509)(708 \text{ psia}) = 678.3 \text{ psia} \end{aligned}$$

The compressibility factor of the gas mixture in the reservoir and the mass of this gas are

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{\text{cr},m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_R &= \frac{P_m}{P'_{\text{cr},m}} = \frac{2000 \text{ psia}}{678.3 \text{ psia}} = 2.949 \end{aligned} \right\} Z_m = 0.963 \quad (\text{Fig. A-15})$$

$$m = \frac{PV}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.963)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = 4.612 \times 10^6 \text{ lbm}$$

The enthalpy departure factors in the reservoir and the surface are (from EES or Fig. A-29)

$$\left. \begin{aligned} T_{R1} &= \frac{T_m}{T'_{cr,m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_{R1} &= \frac{P_m}{P'_{cr,m}} = \frac{2000 \text{ psia}}{678.3 \text{ psia}} = 2.949 \end{aligned} \right\} Z_{h1} = 0.703$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_m}{T'_{cr,m}} = \frac{660 \text{ R}}{375.0 \text{ R}} = 1.76 \\ P_{R2} &= \frac{P_m}{P'_{cr,m}} = \frac{20 \text{ psia}}{678.3 \text{ psia}} = 0.0295 \end{aligned} \right\} Z_{h2} = 0.0112$$

The enthalpy change for the ideal gas mixture is

$$(h_2 - h_1)_{\text{ideal}} = c_p (T_2 - T_1) = (0.506 \text{ Btu/lbm} \cdot \text{R})(760 - 660) \text{ R} = 50.6 \text{ Btu/lbm}$$

The enthalpy change with departure factors is

$$\begin{aligned} h_2 - h_1 &= (h_2 - h_1)_{\text{ideal}} - RT'_{cr,m} (Z_{h2} - Z_{h1}) \\ &= 50.6 - (0.1096)(375)(0.0112 - 0.703) \\ &= 79.0 \text{ Btu/lbm} \end{aligned}$$

The work input is then

$$W_{\text{in}} = m(h_2 - h_1) = (4.612 \times 10^6 \text{ lbm})(79.0 \text{ Btu/lbm}) = \mathbf{3.64 \times 10^8 \text{ Btu}}$$

**13-70** In a liquid-oxygen plant, it is proposed that the pressure and temperature of air be adiabatically reduced. It is to be determined whether this process is possible and the work produced is to be determined using Kay's rule and the departure charts.

**Assumptions** Air is a gas mixture with 21% O<sub>2</sub> and 79% N<sub>2</sub>, by mole.

**Properties** The molar masses of O<sub>2</sub> and N<sub>2</sub> are 32.0 and 28.0 kg/kmol, respectively. The critical properties are 154.8 K, 5.08 MPa for O<sub>2</sub> and 126.2 K and 3.39 MPa for N<sub>2</sub> (Table A-1).

**Analysis** To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$\begin{aligned}T'_{cr,m} &= \sum y_i T_{cr,i} = y_{O_2} T_{cr,O_2} + y_{N_2} T_{cr,N_2} \\&= (0.21)(154.8 \text{ K}) + (0.79)(126.2 \text{ K}) = 132.2 \text{ K} \\P'_{cr,m} &= \sum y_i P_{cr,i} = y_{O_2} P_{cr,O_2} + y_{N_2} P_{cr,N_2} \\&= (0.21)(5.08 \text{ MPa}) + (0.79)(3.39 \text{ MPa}) = 3.745 \text{ MPa}\end{aligned}$$

The enthalpy and entropy departure factors at the initial and final states are (from EES)

$$\left. \begin{aligned}T_{R1} &= \frac{T_{m1}}{T'_{cr,m}} = \frac{283 \text{ K}}{132.2 \text{ K}} = 2.141 \\P_{R1} &= \frac{P_{m1}}{P'_{cr,m}} = \frac{9 \text{ MPa}}{3.745 \text{ MPa}} = 2.403\end{aligned} \right\} \begin{aligned}Z_{h1} &= 0.513 \\Z_{s1} &= 0.235\end{aligned}$$

$$\left. \begin{aligned}T_{R2} &= \frac{T_{m2}}{T'_{cr,m}} = \frac{200 \text{ K}}{132.2 \text{ K}} = 1.513 \\P_{R2} &= \frac{P_{m2}}{P'_{cr,m}} = \frac{0.050 \text{ MPa}}{3.745 \text{ MPa}} = 0.0134\end{aligned} \right\} \begin{aligned}Z_{h2} &= 0.0069 \\Z_{s2} &= 0.0035\end{aligned}$$

21% O<sub>2</sub>  
79% N<sub>2</sub>  
(by mole)  
9000 kPa  
10°C

The enthalpy and entropy changes of the air under the ideal gas assumption is (Properties are from Table A-17)

$$\begin{aligned}(h_2 - h_1)_{\text{ideal}} &= 199.97 - 283.14 = -83.2 \text{ kJ/kg} \\(s_2 - s_1)_{\text{ideal}} &= s_2^0 - s_1^0 - R \ln \frac{P_2}{P_1} = 1.29559 - 1.64345 - (0.287) \ln \frac{50}{9000} = 1.1425 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

With departure factors, the enthalpy change (i.e., the work output) and the entropy change are

$$\begin{aligned}w_{\text{out}} &= h_1 - h_2 = (h_1 - h_2)_{\text{ideal}} - RT'_{cr}(Z_{h1} - Z_{h2}) \\&= 83.2 - (0.287)(132.2)(0.513 - 0.0069) = \mathbf{64.0 \text{ kJ/kg}} \\s_2 - s_1 &= (s_2 - s_1)_{\text{ideal}} - R(Z_{s2} - Z_{s1}) \\&= 1.1425 - (0.287)(0.0035 - 0.235) = \mathbf{1.209 \text{ kJ/kg} \cdot \text{K}}\end{aligned}$$

The entropy change in this case is equal to the entropy generation during the process since the process is adiabatic. The positive value of entropy generation shows that this process is possible.

**13-71E** [Also solved by EES on enclosed CD] A gas mixture with known mass fractions is accelerated through a nozzle from a specified state to a specified pressure. For a specified isentropic efficiency, the exit temperature and the exit velocity of the mixture are to be determined.

**Assumptions** 1 Under specified conditions both  $N_2$  and  $CO_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture. 2 The nozzle is adiabatic and thus heat transfer is negligible. 3 This is a steady-flow process. 4 Potential energy changes are negligible.

**Properties** The specific heats of  $N_2$  and  $CO_2$  are  $c_{p,N_2} = 0.248$  Btu/lbm·R,  $c_{v,N_2} = 0.177$  Btu/lbm·R,  $c_{p,CO_2} = 0.203$  Btu/lbm·R, and  $c_{v,CO_2} = 0.158$  Btu/lbm·R. (Table A-2E).

**Analysis** (a) Under specified conditions both  $N_2$  and  $CO_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture. The  $c_p$ ,  $c_v$ , and  $k$  values of this mixture are determined from

$$\begin{aligned} c_{p,m} &= \sum mf_i c_{p,i} = mf_{N_2} c_{p,N_2} + mf_{CO_2} c_{p,CO_2} \\ &= (0.8)(0.248) + (0.2)(0.203) \\ &= 0.239 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\begin{aligned} c_{v,m} &= \sum mf_i c_{v,i} = mf_{N_2} c_{v,N_2} + mf_{CO_2} c_{v,CO_2} \\ &= (0.8)(0.177) + (0.2)(0.158) \\ &= 0.173 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$k_m = \frac{c_{p,m}}{c_{v,m}} = \frac{0.239 \text{ Btu/lbm} \cdot \text{R}}{0.173 \text{ Btu/lbm} \cdot \text{R}} = 1.382$$

Therefore, the  $N_2$ - $CO_2$  mixture can be treated as a single ideal gas with above properties. Then the isentropic exit temperature can be determined from

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (1800 \text{ R}) \left( \frac{12 \text{ psia}}{90 \text{ psia}} \right)^{0.382/1.382} = 1031.3 \text{ R}$$

From the definition of adiabatic efficiency,

$$\eta_N = \frac{h_1 - h_2}{h_1 - h_{2s}} = \frac{c_p(T_1 - T_2)}{c_p(T_1 - T_{2s})} \longrightarrow 0.92 = \frac{1800 - T_2}{1800 - 1031.3} \longrightarrow T_2 = 1092.8 \text{ R}$$

(b) Noting that,  $q = w = 0$ , from the steady-flow energy balance relation,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi_0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2$$

$$0 = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$V_2 = \sqrt{2c_p(T_1 - T_2)} = \sqrt{2(0.239 \text{ Btu/lbm} \cdot \text{R})(1800 - 1092.8) \text{ R} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 2,909 \text{ ft/s}$$

**13-72E EES** Problem 13-71E is reconsidered. The problem is first to be solved and then, for all other conditions being the same, the problem is to be resolved to determine the composition of the nitrogen and carbon dioxide that is required to have an exit velocity of 2000 ft/s at the nozzle exit.

**Analysis** The problem is solved using EES, and the solution is given below.

"Input Data"

mf\_N2 = 0.8 "Mass fraction for the nitrogen, lbm\_N2/lbm\_mix"  
 mf\_CO2 = 0.2 "Mass fraction for the carbon dioxide, lbm\_CO2/lbm\_mix"  
 T[1] = 1800 [R]  
 P[1] = 90 [psia]  
 Vel[1] = 0 [ft/s]  
 P[2] = 12 [psia]  
 Eta\_N = 0.92 "Nozzle adiabatic efficiency"

"Enthalpy property data per unit mass of mixture:"

" Note: EES calculates the enthalpy of ideal gases referenced to the enthalpy of formation as  $h = h_f + (h_T - h_{537})$  where  $h_f$  is the enthalpy of formation such that the enthalpy of the elements or their stable compounds is zero at 77 F or 537 R, see Chapter 14. The enthalpy of formation is often negative; thus, the enthalpy of ideal gases can be negative at a given temperature. This is true for CO2 in this problem."

$h[1] = mf\_N2 * \text{enthalpy}(N2, T=T[1]) + mf\_CO2 * \text{enthalpy}(CO2, T=T[1])$   
 $h[2] = mf\_N2 * \text{enthalpy}(N2, T=T[2]) + mf\_CO2 * \text{enthalpy}(CO2, T=T[2])$

**13-73** A piston-cylinder device contains a gas mixture at a given state. Heat is transferred to the mixture. The amount of heat transfer and the entropy change of the mixture are to be determined.

**Assumptions 1** Under specified conditions both  $H_2$  and  $N_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** Kinetic and potential energy changes are negligible.

**Properties** The constant pressure specific heats of  $H_2$  and  $N_2$  at 450 K are 14.501 kJ/kg·K and 1.049 kJ/kg·K, respectively. (Table A-2b).

**Analysis** (a) Noting that  $P_2 = P_1$  and  $V_2 = 2V_1$ ,

$$\frac{P_2 V_2}{T_2} = \frac{P_1 V_1}{T_1} \longrightarrow T_2 = \frac{2V_1}{V_1} T_1 = 2T_1 = (2)(300 \text{ K}) = 600 \text{ K}$$

Also  $P = \text{constant}$ . Then from the closed system energy balance relation,

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ Q_{\text{in}} - W_{b,\text{out}} &= \Delta U \rightarrow Q_{\text{in}} = \Delta H \end{aligned}$$

since  $W_b$  and  $\Delta U$  combine into  $\Delta H$  for quasi-equilibrium constant pressure processes.

$$\begin{aligned} Q_{\text{in}} = \Delta H &= \Delta H_{H_2} + \Delta H_{N_2} = [mc_{p,\text{avg}}(T_2 - T_1)]_{H_2} + [mc_{p,\text{avg}}(T_2 - T_1)]_{N_2} \\ &= (0.5 \text{ kg})(14.501 \text{ kJ/kg} \cdot \text{K})(600 - 300) \text{ K} + (1.6 \text{ kg})(1.049 \text{ kJ/kg} \cdot \text{K})(600 - 300) \text{ K} \\ &= \mathbf{2679 \text{ kJ}} \end{aligned}$$

(b) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of the mixture during this process is

$$\begin{aligned} \Delta S_{H_2} &= [m(s_2 - s_1)]_{H_2} = m_{H_2} \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{H_2} = m_{H_2} \left( c_p \ln \frac{T_2}{T_1} \right)_{H_2} \\ &= (0.5 \text{ kg})(14.501 \text{ kJ/kg} \cdot \text{K}) \ln \frac{600 \text{ K}}{300 \text{ K}} \\ &= 5.026 \text{ kJ/K} \end{aligned}$$

$$\begin{aligned} \Delta S_{N_2} &= [m(s_2 - s_1)]_{N_2} = m_{N_2} \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{N_2} = m_{N_2} \left( c_p \ln \frac{T_2}{T_1} \right)_{N_2} \\ &= (1.6 \text{ kg})(1.049 \text{ kJ/kg} \cdot \text{K}) \ln \frac{600 \text{ K}}{300 \text{ K}} \\ &= 1.163 \text{ kJ/K} \end{aligned}$$

$$\Delta S_{\text{total}} = \Delta S_{H_2} + \Delta S_{N_2} = 5.026 \text{ kJ/K} + 1.163 \text{ kJ/K} = \mathbf{6.19 \text{ kJ/K}}$$

**13-74** Heat is transferred to a gas mixture contained in a piston cylinder device. The initial state and the final temperature are given. The heat transfer is to be determined for the ideal gas and non-ideal gas cases.

**Properties** The molar masses of  $H_2$  and  $N_2$  are 2.0, and 28.0 kg/kmol. (Table A-1).

**Analysis** From the energy balance relation,

$$E_{in} - E_{out} = \Delta E$$

$$Q_{in} - W_{b,out} = \Delta U$$

$$Q_{in} = \Delta H = \Delta H_{H_2} + \Delta H_{N_2} = N_{H_2} (\bar{h}_2 - \bar{h}_1)_{H_2} + N_{N_2} (\bar{h}_2 - \bar{h}_1)_{N_2}$$

since  $W_b$  and  $\Delta U$  combine into  $\Delta H$  for quasi-equilibrium constant pressure processes

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{6 \text{ kg}}{2 \text{ kg/kmol}} = 3 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{21 \text{ kg}}{28 \text{ kg/kmol}} = 0.75 \text{ kmol}$$

(a) Assuming ideal gas behavior, the inlet and exit enthalpies of  $H_2$  and  $N_2$  are determined from the ideal gas tables to be

$$H_2: \quad \bar{h}_1 = \bar{h}_{@160 \text{ K}} = 4,535.4 \text{ kJ/kmol}, \quad \bar{h}_2 = \bar{h}_{@200 \text{ K}} = 5,669.2 \text{ kJ/kmol}$$

$$N_2: \quad \bar{h}_1 = \bar{h}_{@160 \text{ K}} = 4,648 \text{ kJ/kmol}, \quad \bar{h}_2 = \bar{h}_{@200 \text{ K}} = 5,810 \text{ kJ/kmol}$$

$$\text{Thus, } Q_{ideal} = 3 \times (5,669.2 - 4,535.4) + 0.75 \times (5,810 - 4,648) = \mathbf{4273 \text{ kJ}}$$

(b) Using Amagat's law and the generalized enthalpy departure chart, the enthalpy change of each gas is determined to be

$$H_2: \quad \left. \begin{aligned} T_{R1,H_2} &= \frac{T_{m,1}}{T_{cr,H_2}} = \frac{160}{33.3} = 4.805 \\ P_{R1,H_2} &= P_{R2,H_2} = \frac{P_m}{P_{cr,H_2}} = \frac{5}{1.30} = 3.846 \\ T_{R2,H_2} &= \frac{T_{m,2}}{T_{cr,H_2}} = \frac{200}{33.3} = 6.006 \end{aligned} \right\} \begin{aligned} Z_{h_1} &\cong 0 \\ Z_{h_2} &\cong 0 \end{aligned} \quad (\text{Fig. A-29})$$

Thus  $H_2$  can be treated as an ideal gas during this process.

$$N_2: \quad \left. \begin{aligned} T_{R1,N_2} &= \frac{T_{m,1}}{T_{cr,N_2}} = \frac{160}{126.2} = 1.27 \\ P_{R1,N_2} &= P_{R2,N_2} = \frac{P_m}{P_{cr,N_2}} = \frac{5}{3.39} = 1.47 \\ T_{R2,N_2} &= \frac{T_{m,2}}{T_{cr,N_2}} = \frac{200}{126.2} = 1.58 \end{aligned} \right\} \begin{aligned} Z_{h_1} &= 1.3 \\ Z_{h_2} &= 0.7 \end{aligned} \quad (\text{Fig. A-29})$$

Therefore,

$$(\bar{h}_2 - \bar{h}_1)_{H_2} = (\bar{h}_2 - \bar{h}_1)_{H_2,ideal} = 5,669.2 - 4,535.4 = 1,133.8 \text{ kJ/kmol}$$

$$\begin{aligned} (\bar{h}_2 - \bar{h}_1)_{N_2} &= R_u T_{cr} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{ideal} \\ &= (8.314 \text{ kPa} \cdot \text{m}^3 / \text{kmol} \cdot \text{K})(126.2 \text{ K})(1.3 - 0.7) + (5,810 - 4,648) \text{ kJ/kmol} = 1,791.5 \text{ kJ/kmol} \end{aligned}$$

$$\text{Substituting, } Q_{in} = (3 \text{ kmol})(1,133.8 \text{ kJ/kmol}) + (0.75 \text{ kmol})(1,791.5 \text{ kJ/kmol}) = \mathbf{4745 \text{ kJ}}$$

**13-75** Heat is transferred to a gas mixture contained in a piston cylinder device discussed in previous problem. The total entropy change and the exergy destruction are to be determined for two cases.

**Analysis** The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the piston-cylinder device and its immediate surroundings so that the boundary temperature of the extended system is the environment temperature at all times. It gives

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$

$$\frac{Q_{\text{in}}}{T_{\text{boundary}}} + S_{\text{gen}} = \Delta S_{\text{water}} \rightarrow S_{\text{gen}} = m(s_2 - s_1) - \frac{Q_{\text{in}}}{T_{\text{surr}}}$$

Then the exergy destroyed during a process can be determined from its definition  $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ .

(a) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of a component in the mixture during this process is

$$\Delta S_i = m_i \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) = m_i c_{p,i} \ln \frac{T_2}{T_1}$$

Assuming ideal gas behavior and using  $c_p$  values at the average temperature, the  $\Delta S$  of  $\text{H}_2$  and  $\text{N}_2$  are determined from

$$\Delta S_{\text{H}_2, \text{ideal}} = (6 \text{ kg})(13.60 \text{ kJ/kg} \cdot \text{K}) \ln \frac{200 \text{ K}}{160 \text{ K}} = 18.21 \text{ kJ/K}$$

$$\Delta S_{\text{N}_2, \text{ideal}} = (21 \text{ kg})(1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{200 \text{ K}}{160 \text{ K}} = 4.87 \text{ kJ/K}$$

and

$$S_{\text{gen}} = 18.21 \text{ kJ/K} + 4.87 \text{ kJ/K} - \frac{4273 \text{ kJ}}{303 \text{ K}} = \mathbf{8.98 \text{ kJ/K}}$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (303 \text{ K})(8.98 \text{ kJ/K}) = \mathbf{2721 \text{ kJ}}$$

(b) Using Amagat's law and the generalized entropy departure chart, the entropy change of each gas is determined to be

$$\text{H}_2: \left. \begin{aligned} T_{R_1, \text{H}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{H}_2}} = \frac{160}{33.3} = 4.805 \\ P_{R_1, \text{H}_2} &= P_{R_2, \text{H}_2} = \frac{P_m}{P_{\text{cr}, \text{H}_2}} = \frac{5}{1.30} = 3.846 \\ T_{R_2, \text{H}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{H}_2}} = \frac{200}{33.3} = 6.006 \end{aligned} \right\} \begin{aligned} Z_{s_1} &\cong 1 \\ Z_{s_2} &\cong 1 \end{aligned} \quad (\text{Table A-30})$$

Thus  $\text{H}_2$  can be treated as an ideal gas during this process.

$$\text{N}_2: \left. \begin{aligned} T_{R_1, \text{N}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{N}_2}} = \frac{160}{126.2} = 1.268 \\ P_{R_1, \text{N}_2} &= P_{R_2, \text{N}_2} = \frac{P_m}{P_{\text{cr}, \text{N}_2}} = \frac{5}{3.39} = 1.475 \\ T_{R_2, \text{N}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{N}_2}} = \frac{200}{126.2} = 1.585 \end{aligned} \right\} \begin{aligned} Z_{s_1} &= 0.8 \\ Z_{s_2} &= 0.4 \end{aligned} \quad (\text{Table A-30})$$

Therefore,

$$\Delta S_{\text{H}_2} = \Delta S_{\text{H}_2, \text{ideal}} = 18.21 \text{ kJ/K}$$

$$\begin{aligned}\Delta S_{\text{N}_2} &= N_{\text{N}_2} R_u (Z_{s_1} - Z_{s_2}) + \Delta S_{\text{N}_2, \text{ideal}} \\ &= (0.75 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(0.8 - 0.4) + (4.87 \text{ kJ/K}) \\ &= 7.37 \text{ kJ/K}\end{aligned}$$

$$\Delta S_{\text{surr}} = \frac{Q_{\text{surr}}}{T_0} = \frac{-4745 \text{ kJ}}{303 \text{ K}} = -15.66 \text{ kJ/K}$$

and

$$S_{\text{gen}} = 18.21 \text{ kJ/K} + 7.37 \text{ kJ/K} - \frac{4745 \text{ kJ}}{303 \text{ K}} = \mathbf{9.92 \text{ kJ/K}}$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (303 \text{ K})(9.92 \text{ kJ/K}) = \mathbf{3006 \text{ kJ}}$$

**13-76** Air is compressed isothermally in a steady-flow device. The power input to the compressor and the rate of heat rejection are to be determined for ideal and non-ideal gas cases.

**Assumptions 1** This is a steady-flow process. **2** The kinetic and potential energy changes are negligible.

**Properties** The molar mass of air is 29.0 kg/kmol. (Table A-1).

**Analysis** The mass flow rate of air can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{2.90 \text{ kg/s}}{29.0 \text{ kg/kmol}} = 0.10 \text{ kmol/s}$$

(a) Assuming ideal gas behavior, the  $\Delta h$  and  $\Delta s$  of air during this process is

$$\begin{aligned}\Delta \bar{h} &= 0 \text{ (isothermal process)} \\ \Delta \bar{s} &= \bar{c}_p \ln \frac{T_2}{T_1} - R_u \ln \frac{P_2}{P_1} = -R_u \ln \frac{P_2}{P_1} \\ &= -(8.314 \text{ kJ/kg} \cdot \text{K}) \ln \frac{8 \text{ MPa}}{4 \text{ MPa}} = -5.763 \text{ kJ/kmol} \cdot \text{K}\end{aligned}$$

Disregarding any changes in kinetic and potential energies, the steady-flow energy balance equation for the isothermal process of an ideal gas reduces to

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{0 (steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{W}_{\text{in}} + \dot{N}\bar{h}_1 &= \dot{Q}_{\text{out}} + \dot{N}\bar{h}_2 \\ \dot{W}_{\text{in}} - \dot{Q}_{\text{out}} &= \dot{N}\Delta \bar{h}^{\text{0}} = 0 \longrightarrow \dot{W}_{\text{in}} = \dot{Q}_{\text{out}}\end{aligned}$$

Also for an isothermal, internally reversible process the heat transfer is related to the entropy change by

$$Q = T\Delta S = NT\Delta \bar{s},$$

$$\dot{Q} = \dot{N}T\Delta \bar{s} = (0.10 \text{ kmol/s})(200 \text{ K})(-5.763 \text{ kJ/kmol} \cdot \text{K}) = -115.3 \text{ kW} \rightarrow \dot{Q}_{\text{out}} = 115.3 \text{ kW}$$

Therefore,

$$\dot{W}_{\text{in}} = \dot{Q}_{\text{out}} = \mathbf{115.3 \text{ kW}}$$

(b) Using Amagat's law and the generalized charts, the enthalpy and entropy changes of each gas are determined from

$$\begin{aligned}\bar{h}_2 - \bar{h}_1 &= R_u T_{cr} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}}^{\text{0}} \\ \bar{s}_2 - \bar{s}_1 &= R_u (Z_{s_1} - Z_{s_2}) + (\bar{s}_2 - \bar{s}_1)_{\text{ideal}}\end{aligned}$$

where

$$\left. \begin{aligned}P_{R_1} &= \frac{P_{m,1}}{P_{\text{cr},N_2}} = \frac{4}{3.39} = 1.18 \\ N_2: \quad T_{R_1} &= T_{R_2} = \frac{T_m}{T_{\text{cr},N_2}} = \frac{220}{126.2} = 1.74 \\ P_{R_2} &= \frac{P_{m,2}}{P_{\text{cr},N_2}} = \frac{8}{3.39} = 2.36\end{aligned} \right\} \begin{aligned}Z_{h_1} &= 0.4, Z_{s_1} = 0.2 \\ Z_{h_2} &= 0.8, Z_{s_2} = 0.35\end{aligned} \quad \text{(Tables A-29 and A-30)}$$

$$\text{O}_2: \left. \begin{aligned} P_{R_1} &= \frac{P_{m,1}}{P_{\text{cr},\text{O}_2}} = \frac{4}{5.08} = 0.787 \\ T_{R_1} = T_{R_2} &= \frac{T_m}{T_{\text{cr},\text{O}_2}} = \frac{220}{154.8} = 1.421 \\ P_{R_2} &= \frac{P_{m,2}}{P_{\text{cr},\text{O}_2}} = \frac{8}{5.08} = 1.575 \end{aligned} \right\} \begin{aligned} Z_{h_1} &= 0.4, Z_{s_1} = 0.25 \\ Z_{h_2} &= 1.0, Z_{s_2} = 0.5 \end{aligned} \quad (\text{Tables A-29 and A-30})$$

Then,

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= y_i \Delta \bar{h}_i = y_{\text{N}_2} (\bar{h}_2 - \bar{h}_1)_{\text{N}_2} + y_{\text{O}_2} (\bar{h}_2 - \bar{h}_1)_{\text{O}_2} \\ &= (0.79)(8.314)(126.2)(0.4 - 0.8) + (0.21)(8.314)(154.8)(0.4 - 1.0) + 0 \\ &= -494 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= y_i \Delta \bar{s}_i = y_{\text{N}_2} (\bar{s}_2 - \bar{s}_1)_{\text{N}_2} + y_{\text{O}_2} (\bar{s}_2 - \bar{s}_1)_{\text{O}_2} \\ &= (0.79)(8.314)(0.2 - 0.35) + (0.21)(8.314)(0.25 - 0.5) + (-5.763) \\ &= -7.18 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

Thus,

$$\dot{Q}_{\text{out}} = -\dot{N}T\Delta\bar{s} = -(0.10 \text{ kmol/s})(200 \text{ K})(-7.18 \text{ kJ/kmol} \cdot \text{K}) = \mathbf{143.6 \text{ kW}}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{W}_{\text{in}} + \dot{N}\bar{h}_1 = \dot{Q}_{\text{out}} + \dot{N}\bar{h}_2$$

$$\dot{W}_{\text{in}} = \dot{Q}_{\text{out}} + \dot{N}(\bar{h}_2 - \bar{h}_1) \longrightarrow \dot{W}_{\text{in}} = 143.6 \text{ kW} + (0.10 \text{ kmol/s})(-494 \text{ kJ/kmol}) = \mathbf{94.2 \text{ kW}}$$

**13-77 EES** Problem 13-76 is reconsidered. The results obtained by assuming ideal behavior, real gas behavior with Amagat's law, and real gas behavior with EES data are to be compared.

**Analysis** The problem is solved using EES, and the solution is given below.

**13-78** The volumetric fractions of the constituents of a mixture of products of combustion are given. The average molar mass of the mixture, the average specific heat, and the partial pressure of the water vapor in the mixture are to be determined.

**Assumptions** Under specified conditions all  $N_2$ ,  $O_2$ ,  $H_2O$ , and  $CO_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Properties** The molar masses of  $CO_2$ ,  $H_2O$ ,  $O_2$ , and  $N_2$  are 44.0, 18.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1). The specific heats of  $CO_2$ ,  $H_2O$ ,  $O_2$ , and  $N_2$  at 600 K are 1.075, 2.015, 1.003, and 1.075 kJ/kg.K, respectively (Table A-2b). The specific heat of water vapor at 600 K is obtained from EES.

**Analysis** For convenience, consider 100 kmol of mixture. Noting that volume fractions are equal to mole fractions in ideal gas mixtures, the average molar mass of the mixture is determined to be

$$\begin{aligned} M_m &= \frac{N_{CO_2} M_{CO_2} + N_{H_2O} M_{H_2O} + N_{O_2} M_{O_2} + N_{N_2} M_{N_2}}{N_{CO_2} + N_{H_2O} + N_{O_2} + N_{N_2}} \\ &= \frac{(4.89 \text{ kmol})(44 \text{ kg/kmol}) + (6.50)(18) + (12.20)(32) + (76.41)(28)}{(4.89 + 6.50 + 12.20 + 76.41) \text{ kmol}} \\ &= \mathbf{28.62 \text{ kg/kmol}} \end{aligned}$$

76.41%  $N_2$   
12.20%  $O_2$   
6.50%  $H_2O$   
4.89%  $CO_2$

600 K  
200 kPa

The average specific heat is determined from

$$\begin{aligned} c_{p,m} &= \frac{N_{CO_2} c_{p,CO_2} M_{CO_2} + N_{H_2O} c_{p,H_2O} M_{H_2O} + N_{O_2} c_{p,O_2} M_{O_2} + N_{N_2} c_{p,N_2} M_{N_2}}{N_{CO_2} + N_{H_2O} + N_{O_2} + N_{N_2}} \\ &= \frac{(4.89 \text{ kmol})(1.075 \text{ kJ/kg.K})(44 \text{ kg/kmol}) + (6.50)(2.015)(18) + (12.20)(1.003)(32) + (76.41)(1.075)(28)}{(4.89 + 6.50 + 12.20 + 76.41) \text{ kmol}} \\ &= \mathbf{31.59 \text{ kJ/kmol.K}} \end{aligned}$$

The partial pressure of the water in the mixture is

$$\begin{aligned} y_v &= \frac{N_{H_2O}}{N_{CO_2} + N_{H_2O} + N_{O_2} + N_{N_2}} = \frac{6.50 \text{ kmol}}{(4.89 + 6.50 + 12.20 + 76.41) \text{ kmol}} = 0.0650 \\ P_v &= y_v P_m = (0.0650)(200 \text{ kPa}) = \mathbf{13.0 \text{ kPa}} \end{aligned}$$

**Special Topic: Chemical Potential and the Separation Work of Mixtures**

**13-79C** No, a process that separates a mixture into its components without requiring any work (exergy) input is impossible since such a process would violate the 2<sup>nd</sup> law of thermodynamics.

**13-80C** Yes, the volume of the mixture can be more or less than the sum of the initial volumes of the mixing liquids because of the attractive or repulsive forces acting between dissimilar molecules.

**13-81C** The person who claims that the temperature of the mixture can be higher than the temperatures of the components is right since the total enthalpy of the mixture of two components at the same pressure and temperature, in general, is not equal to the sum of the total enthalpies of the individual components before mixing, the difference being the enthalpy (or heat) of mixing, which is the heat released or absorbed as two or more components are mixed isothermally.

**13-82C** Mixtures or solutions in which the effects of molecules of different components on each other are negligible are called ideal solutions (or ideal mixtures). The ideal-gas mixture is just one category of ideal solutions. For ideal solutions, the enthalpy change and the volume change due to mixing are zero, but the entropy change is not. The chemical potential of a component of an ideal mixture is independent of the identity of the other constituents of the mixture. The chemical potential of a component in an ideal mixture is equal to the Gibbs function of the pure component.

**13-83** Brackish water is used to produce fresh water. The minimum power input and the minimum height the brackish water must be raised by a pump for reverse osmosis are to be determined.

**Assumptions** 1 The brackish water is an ideal solution since it is dilute. 2 The total dissolved solids in water can be treated as table salt (NaCl). 3 The environment temperature is also 12°C.

**Properties** The molar masses of water and salt are  $M_w = 18.0 \text{ kg/kmol}$  and  $M_s = 58.44 \text{ kg/kmol}$ . The gas constant of pure water is  $R_w = 0.4615 \text{ kJ/kg} \cdot \text{K}$  (Table A-1). The density of fresh water is  $1000 \text{ kg/m}^3$ .

**Analysis** First we determine the mole fraction of pure water in brackish water using Eqs. 13-4 and 13-5. Noting that  $\text{mf}_s = 0.00078$  and  $\text{mf}_w = 1 - \text{mf}_s = 0.99922$ ,

$$M_m = \frac{1}{\sum \frac{\text{mf}_i}{M_i}} = \frac{1}{\frac{\text{mf}_s}{M_s} + \frac{\text{mf}_w}{M_w}} = \frac{1}{\frac{0.00078}{58.44} + \frac{0.99922}{18.0}} = 18.01 \text{ kg/kmol}$$

$$y_i = \text{mf}_i \frac{M_m}{M_i} \rightarrow y_w = \text{mf}_w \frac{M_m}{M_w} = (0.99922) \frac{18.01 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.99976$$

The minimum work input required to produce 1 kg of freshwater from brackish water is

$$w_{\min, \text{in}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg} \cdot \text{K})(285.15 \text{ K}) \ln(1/0.99976) = 0.03159 \text{ kJ/kg fresh water}$$

Therefore, 0.03159 kJ of work is needed to produce 1 kg of fresh water is mixed with seawater reversibly. Therefore, the required power input to produce fresh water at the specified rate is

$$\dot{W}_{\min, \text{in}} = \rho \dot{V} w_{\min, \text{in}} = (1000 \text{ kg/m}^3)(0.280 \text{ m}^3/\text{s})(0.03159 \text{ kJ/kg}) \left( \frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = \mathbf{8.85 \text{ kW}}$$

The minimum height to which the brackish water must be pumped is

$$\Delta z_{\min} = \frac{w_{\min, \text{in}}}{g} = \left( \frac{0.03159 \text{ kJ/kg}}{9.81 \text{ m/s}^2} \right) \left( \frac{1 \text{ kg} \cdot \text{m/s}^2}{1 \text{ N}} \right) \left( \frac{1000 \text{ N} \cdot \text{m}}{1 \text{ kJ}} \right) = \mathbf{3.22 \text{ m}}$$

**13-84** A river is discharging into the ocean at a specified rate. The amount of power that can be generated is to be determined.

**Assumptions** 1 The seawater is an ideal solution since it is dilute. 2 The total dissolved solids in water can be treated as table salt (NaCl). 3 The environment temperature is also 15°C.

**Properties** The molar masses of water and salt are  $M_w = 18.0 \text{ kg/kmol}$  and  $M_s = 58.44 \text{ kg/kmol}$ . The gas constant of pure water is  $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$  (Table A-1). The density of river water is  $1000 \text{ kg/m}^3$ .

**Analysis** First we determine the mole fraction of pure water in ocean water using Eqs. 13-4 and 13-5. Noting that  $\text{mf}_s = 0.035$  and  $\text{mf}_w = 1 - \text{mf}_s = 0.965$ ,

$$M_m = \frac{1}{\sum \frac{\text{mf}_i}{M_i}} = \frac{1}{\frac{\text{mf}_s}{M_s} + \frac{\text{mf}_w}{M_w}} = \frac{1}{\frac{0.035}{58.44} + \frac{0.965}{18.0}} = 18.45 \text{ kg/kmol}$$

$$y_i = \text{mf}_i \frac{M_m}{M_i} \rightarrow y_w = \text{mf}_w \frac{M_m}{M_w} = (0.965) \frac{18.45 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.9891$$

The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is

$$w_{\text{max, out}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(288.15 \text{ K})\ln(1/0.9891) = 1.46 \text{ kJ/kg fresh water}$$

Therefore, 1.46 kJ of work can be produced as 1 kg of fresh water is mixed with seawater reversibly. Therefore, the power that can be generated as a river with a flow rate of  $400,000 \text{ m}^3/\text{s}$  mixes reversibly with seawater is

$$\dot{W}_{\text{max out}} = \rho \dot{V} w_{\text{max out}} = (1000 \text{ kg/m}^3)(4 \times 10^5 \text{ m}^3/\text{s})(1.46 \text{ kJ/kg}) \left( \frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = 582 \times 10^6 \text{ kW}$$

**Discussion** This is more power than produced by all nuclear power plants (112 of them) in the U.S., which shows the tremendous amount of power potential wasted as the rivers discharge into the seas.

**13-85 EES** Problem 13-84 is reconsidered. The effect of the salinity of the ocean on the maximum power generated is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

"Properties:"

$M_w = 18.0$  [kg/kmol] "Molar masses of water"

$M_s = 58.44$  [kg/kmol] "Molar masses of salt"

$R_w = 0.4615$  [kJ/kg-K] "Gas constant of pure water"

$\rho_{h,w} = 1000$  [kg/m<sup>3</sup>] "density of river water"

$\dot{V} = 4E5$  [m<sup>3</sup>/s]

$T_0 = 15$  [C]

"Analysis:"

First we determine the mole fraction of pure water in ocean water using Eqs. 13-4 and 13-5. "

$mf_s = 0.035$  "mass fraction of the salt in seawater = salinity"

$mf_w = 1 - mf_s$  "mass fraction of the water in seawater"

"Molar mass of the seawater is:"

$M_m = 1/(mf_s/M_s + mf_w/M_w)$

"Mole fraction of the water is:"

$y_w = mf_w * M_m / M_w$

"The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is:"

$w_{maxout} = R_w * (T_0 + 273.15) * \ln(1/y_w)$  "[kJ/kg fresh water]"

"The power that can be generated as a river with a flow rate of 400,000 m<sup>3</sup>/s mixes reversibly with seawater is"

$\dot{W}_{dot,max} = \rho_{h,w} * \dot{V} * w_{maxout}$

"Discussion This is more power than produced by all nuclear power plants (112 of them) in the US., which shows the tremendous amount of power potential wasted as the rivers discharge into the seas."

**13-86E** Brackish water is used to produce fresh water. The mole fractions, the minimum work inputs required to separate 1 lbm of brackish water and to obtain 1 lbm of fresh water are to be determined.

**Assumptions** **1** The brackish water is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is equal to the water temperature.

**Properties** The molar masses of water and salt are  $M_w = 18.0 \text{ lbm/lbmol}$  and  $M_s = 58.44 \text{ lbm/lbmol}$ . The gas constant of pure water is  $R_w = 0.1102 \text{ Btu/lbm} \cdot \text{R}$  (Table A-1E).

**Analysis** (a) First we determine the mole fraction of pure water in brackish water using Eqs. 13-4 and 13-5. Noting that  $\text{mf}_s = 0.0012$  and  $\text{mf}_w = 1 - \text{mf}_s = 0.9988$ ,

$$M_m = \frac{1}{\sum \frac{\text{mf}_i}{M_i}} = \frac{1}{\frac{\text{mf}_s}{M_s} + \frac{\text{mf}_w}{M_w}} = \frac{1}{\frac{0.0012}{58.44} + \frac{0.9988}{18.0}} = 18.015 \text{ lbm/lbmol}$$

$$y_i = \text{mf}_i \frac{M_m}{M_i} \rightarrow y_w = \text{mf}_w \frac{M_m}{M_w} = (0.9988) \frac{18.015 \text{ lbm/lbmol}}{18.0 \text{ lbm/lbmol}} = \mathbf{0.99963}$$

$$y_s = 1 - y_w = 1 - 0.99963 = \mathbf{0.00037}$$

(b) The minimum work input required to separate 1 lbmol of brackish water is

$$\begin{aligned} w_{\min, \text{in}} &= -R_w T_0 (y_w \ln y_w + y_s \ln y_s) \\ &= -(0.1102 \text{ Btu/lbmol} \cdot \text{R})(525 \text{ R})[0.99963 \ln(0.99963) + 0.00037 \ln(0.00037)] \\ &= \mathbf{-0.191 \text{ Btu/lbm brackish water}} \end{aligned}$$

(c) The minimum work input required to produce 1 lbm of freshwater from brackish water is

$$w_{\min, \text{in}} = R_w T_0 \ln(1/y_w) = (0.1102 \text{ Btu/lbm} \cdot \text{R})(525 \text{ R}) \ln(1/0.99963) = \mathbf{0.0214 \text{ Btu/lbm fresh water}}$$

**Discussion** Note that it takes about 9 times work to separate 1 lbm of brackish water into pure water and salt compared to producing 1 lbm of fresh water from a large body of brackish water.

**13-87** A desalination plant produces fresh water from seawater. The second law efficiency of the plant is to be determined.

**Assumptions** **1** The seawater is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is equal to the seawater temperature.

**Properties** The molar masses of water and salt are  $M_w = 18.0 \text{ kg/kmol}$  and  $M_s = 58.44 \text{ kg/kmol}$ . The gas constant of pure water is  $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$  (Table A-1). The density of river water is  $1000 \text{ kg/m}^3$ .

**Analysis** First we determine the mole fraction of pure water in seawater using Eqs. 13-4 and 13-5. Noting that  $\text{mf}_s = 0.032$  and  $\text{mf}_w = 1 - \text{mf}_s = 0.968$ ,

$$M_m = \frac{1}{\sum \frac{\text{mf}_i}{M_i}} = \frac{1}{\frac{\text{mf}_s}{M_s} + \frac{\text{mf}_w}{M_w}} = \frac{1}{\frac{0.032}{58.44} + \frac{0.968}{18.0}} = 18.41 \text{ kg/kmol}$$

$$y_i = \text{mf}_i \frac{M_m}{M_i} \rightarrow y_w = \text{mf}_w \frac{M_m}{M_w} = (0.968) \frac{18.41 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.9900$$

The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is

$$w_{\text{max, out}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(283.15 \text{ K})\ln(1/0.990) = 1.313 \text{ kJ/kg fresh water}$$

The power that can be generated as  $1.4 \text{ m}^3/\text{s}$  fresh water mixes reversibly with seawater is

$$\dot{W}_{\text{max out}} = \rho \dot{V} w_{\text{max out}} = (1000 \text{ kg/m}^3)(1.4 \text{ m}^3/\text{s})(1.313 \text{ kJ/kg}) \left( \frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = 1.84 \text{ kW}$$

Then the second law efficiency of the plant becomes

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{min, in}}}{\dot{W}_{\text{in}}} = \frac{1.83 \text{ MW}}{8.5 \text{ MW}} = 0.216 = \mathbf{21.6\%}$$

**13-88** The power consumption and the second law efficiency of a desalination plant are given. The power that can be produced if the fresh water produced is mixed with the seawater reversibly is to be determined.

**Assumptions** **1** This is a steady-flow process. **2** The kinetic and potential energy changes are negligible.

**Analysis** From the definition of the second law efficiency

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_{\text{actual}}} \rightarrow 0.18 = \frac{\dot{W}_{\text{rev}}}{3.3 \text{ MW}} \rightarrow \dot{W}_{\text{rev}} = \mathbf{0.594 \text{ MW}}$$

which is the maximum power that can be generated.

**13-89E** It is to be determined if it is possible for an adiabatic liquid-vapor separator to separate wet steam at 100 psia and 90 percent quality, so that the pressure of the outlet streams is greater than 100 psia.

**Analysis** Because the separator divides the inlet stream into the liquid and vapor portions,

$$\dot{m}_2 = x\dot{m}_1 = 0.9\dot{m}_1$$

$$\dot{m}_3 = (1-x)\dot{m}_1 = 0.1\dot{m}_1$$

According to the water property tables at 100 psia (Table A-5E),

$$s_1 = s_f + xs_{fg} = 0.47427 + 0.9 \times 1.12888 = 1.4903 \text{ Btu/lbm} \cdot \text{R}$$

When the increase in entropy principle is adapted to this system, it becomes

$$\dot{m}_2 s_2 + \dot{m}_3 s_3 \geq \dot{m}_1 s_1$$

$$x\dot{m}_1 s_2 + (1-x)\dot{m}_1 s_3 \geq \dot{m}_1 s_1$$

$$0.9s_2 + 0.1s_3 \geq s_1$$

$$\geq 1.4903 \text{ Btu/lbm} \cdot \text{R}$$

To test this hypothesis, let's assume the outlet pressures are 110 psia. Then,

$$s_2 = s_g = 1.5954 \text{ Btu/lbm} \cdot \text{R}$$

$$s_3 = s_f = 0.48341 \text{ Btu/lbm} \cdot \text{R}$$

The left-hand side of the above equation is

$$0.9s_2 + 0.1s_3 = 0.9 \times 1.5954 + 0.1 \times 0.48341 = 1.4842 \text{ Btu/lbm} \cdot \text{R}$$

which is less than the minimum possible specific entropy. Hence, the outlet pressure cannot be 110 psia. Inspection of the water table in light of above equation proves that the pressure at the separator outlet cannot be greater than that at the inlet.

## Review Problems

**13-90** The molar fractions of constituents of air are given. The gravimetric analysis of air and its molar mass are to be determined.

**Assumptions** All the constituent gases and their mixture are ideal gases.

**Properties** The molar masses of  $O_2$ ,  $N_2$ , and Ar are 32.0, 28.0, and 40.0 kg/kmol. (Table A-1).

**Analysis** For convenience, consider 100 kmol of air. Then the mass of each component and the total mass are

$$N_{O_2} = 21 \text{ kmol} \longrightarrow m_{O_2} = N_{O_2} M_{O_2} = (21 \text{ kmol})(32 \text{ kg/kmol}) = 672 \text{ kg}$$

$$N_{N_2} = 78 \text{ kmol} \longrightarrow m_{N_2} = N_{N_2} M_{N_2} = (78 \text{ kmol})(28 \text{ kg/kmol}) = 2184 \text{ kg}$$

$$N_{Ar} = 1 \text{ kmol} \longrightarrow m_{Ar} = N_{Ar} M_{Ar} = (1 \text{ kmol})(40 \text{ kg/kmol}) = 40 \text{ kg}$$

$$m_m = m_{O_2} + m_{N_2} + m_{Ar} = 672 \text{ kg} + 2184 \text{ kg} + 40 \text{ kg} = 2896 \text{ kg}$$

|                                                                                 |
|---------------------------------------------------------------------------------|
| <p>AIR</p> <p>21% <math>O_2</math></p> <p>78% <math>N_2</math></p> <p>1% Ar</p> |
|---------------------------------------------------------------------------------|

Then the mass fraction of each component (gravimetric analysis) becomes

$$mf_{O_2} = \frac{m_{O_2}}{m_m} = \frac{672 \text{ kg}}{2896 \text{ kg}} = 0.232 \text{ or } \mathbf{23.2\%}$$

$$mf_{N_2} = \frac{m_{N_2}}{m_m} = \frac{2184 \text{ kg}}{2896 \text{ kg}} = 0.754 \text{ or } \mathbf{75.4\%}$$

$$mf_{Ar} = \frac{m_{Ar}}{m_m} = \frac{40 \text{ kg}}{2896 \text{ kg}} = 0.014 \text{ or } \mathbf{1.4\%}$$

The molar mass of the mixture is determined from its definitions,

$$M_m = \frac{m_m}{N_m} = \frac{2,896 \text{ kg}}{100 \text{ kmol}} = \mathbf{28.96 \text{ kg / kmol}}$$

**13-91** Using Dalton's law, it is to be shown that  $Z_m = \sum_{i=1}^k y_i Z_i$  for a real-gas mixture.

**Analysis** Using the compressibility factor, the pressure of a component of a real-gas mixture and of the pressure of the gas mixture can be expressed as

$$P_i = \frac{Z_i N_i R_u T_m}{V_m} \quad \text{and} \quad P_m = \frac{Z_m N_m R_u T_m}{V_m}$$

Dalton's law can be expressed as  $P_m = \sum P_i(T_m, V_m)$ . Substituting,

$$\frac{Z_m N_m R_u T_m}{V_m} = \sum \frac{Z_i N_i R_u T_m}{V_m}$$

Simplifying,

$$Z_m N_m = \sum Z_i N_i$$

Dividing by  $N_m$ ,

$$Z_m = \sum y_i Z_i$$

where  $Z_i$  is determined at the mixture temperature and volume.

**13-92** A mixture of carbon dioxide and nitrogen flows through a converging nozzle. The required make up of the mixture on a mass basis is to be determined.

**Assumptions** Under specified conditions  $\text{CO}_2$  and  $\text{N}_2$  can be treated as ideal gases, and the mixture as an ideal gas mixture.

**Properties** The molar masses of  $\text{CO}_2$  and  $\text{N}_2$  are 44.0 and 28.0 kg/kmol, respectively (Table A-1). The specific heat ratios of  $\text{CO}_2$  and  $\text{N}_2$  at 500 K are  $k_{\text{CO}_2} = 1.229$  and  $k_{\text{N}_2} = 1.391$  (Table A-2).

**Analysis** The molar mass of the mixture is determined from

$$M_m = y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{N}_2} M_{\text{N}_2}$$

The molar fractions are related to each other by

$$y_{\text{CO}_2} + y_{\text{N}_2} = 1$$

The gas constant of the mixture is given by

$$R_m = \frac{R_u}{M_m}$$

The specific heat ratio of the mixture is expressed as

$$k = \text{mf}_{\text{CO}_2} k_{\text{CO}_2} + \text{mf}_{\text{N}_2} k_{\text{N}_2}$$

The mass fractions are

$$\text{mf}_{\text{CO}_2} = y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m}$$

$$\text{mf}_{\text{N}_2} = y_{\text{N}_2} \frac{M_{\text{N}_2}}{M_m}$$

The exit velocity equals the speed of sound at 500 K

$$V_{\text{exit}} = \sqrt{k R_m T \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

Substituting the given values and known properties and solving the above equations simultaneously using EES, we find

$$\text{mf}_{\text{CO}_2} = \mathbf{0.838}$$

$$\text{mf}_{\text{N}_2} = \mathbf{0.162}$$

**13-93** The mole numbers, pressure, and temperature of the constituents of a gas mixture are given. The volume of the tank containing this gas mixture is to be determined using three methods.

**Analysis** (a) Under specified conditions both  $N_2$  and  $CH_4$  will considerably deviate from the ideal gas behavior. Treating the mixture as an ideal gas gives

$$N_m = N_{N_2} + N_{CH_4} = 2 \text{ kmol} + 6 \text{ kmol} = 8 \text{ kmol}$$

and

$$V_m = \frac{N_m R_u T_m}{P_m} = \frac{(8 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(200 \text{ K})}{12,000 \text{ kPa}} = \mathbf{1.11 \text{ m}^3}$$

2 kmol  $N_2$   
6 kmol  $CH_4$   
  
200 K  
12 MPa

(b) To use Kay's rule, we first need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of  $N_2$  and  $CH_4$  from Table A-1,

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{2 \text{ kmol}}{8 \text{ kmol}} = 0.25 \quad \text{and} \quad y_{CH_4} = \frac{N_{CH_4}}{N_m} = \frac{6 \text{ kmol}}{8 \text{ kmol}} = 0.75$$

$$\begin{aligned} T'_{cr,m} &= \sum y_i T_{cr,i} = y_{N_2} T_{cr,N_2} + y_{CH_4} T_{cr,CH_4} \\ &= (0.25)(126.2 \text{ K}) + (0.75)(191.1 \text{ K}) = 174.9 \text{ K} \end{aligned}$$

$$\begin{aligned} P'_{cr,m} &= \sum y_i P_{cr,i} = y_{N_2} P_{cr,N_2} + y_{CH_4} P_{cr,CH_4} \\ &= (0.25)(3.39 \text{ MPa}) + (0.75)(4.64 \text{ MPa}) = 4.33 \text{ MPa} \end{aligned}$$

Then,

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{cr,m}} = \frac{200}{174.9} = 1.144 \\ P_R &= \frac{P_m}{P'_{cr,m}} = \frac{12}{4.33} = 2.77 \end{aligned} \right\} Z_m = 0.47 \quad (\text{Fig. A-15})$$

Thus,

$$V_m = \frac{Z_m N_m R_u T_m}{P_m} = Z_m V_{ideal} = (0.47)(1.11 \text{ m}^3) = \mathbf{0.52 \text{ m}^3}$$

(c) To use the Amagat's law for this real gas mixture, we first need to determine the  $Z$  of each component at the mixture temperature and pressure,

$$N_2: \quad \left. \begin{aligned} T_{R,N_2} &= \frac{T_m}{T_{cr,N_2}} = \frac{200}{126.2} = 1.585 \\ P_{R,N_2} &= \frac{P_m}{P_{cr,N_2}} = \frac{12}{3.39} = 3.54 \end{aligned} \right\} Z_{N_2} = 0.85 \quad (\text{Fig. A-15})$$

$$CH_4: \quad \left. \begin{aligned} T_{R,CH_4} &= \frac{T_m}{T_{cr,CH_4}} = \frac{200}{191.1} = 1.047 \\ P_{R,CH_4} &= \frac{P_m}{P_{cr,CH_4}} = \frac{12}{4.64} = 2.586 \end{aligned} \right\} Z_{CH_4} = 0.37 \quad (\text{Fig. A-15})$$

Mixture:

$$Z_m = \sum y_i Z_i = y_{N_2} Z_{N_2} + y_{CH_4} Z_{CH_4} = (0.25)(0.85) + (0.75)(0.37) = 0.49$$

Thus,

$$V_m = \frac{Z_m N_m R_u T_m}{P_m} = Z_m V_{ideal} = (0.49)(1.11 \text{ m}^3) = \mathbf{0.544 \text{ m}^3}$$

**13-94** A stream of gas mixture at a given pressure and temperature is to be separated into its constituents steadily. The minimum work required is to be determined.

**Assumptions** **1** Both the  $N_2$  and  $CO_2$  gases and their mixture are ideal gases. **2** This is a steady-flow process. **3** The kinetic and potential energy changes are negligible.

**Properties** The molar masses of  $N_2$  and  $CO_2$  are 28.0 and 44.0 kg/kmol. (Table A-1).

**Analysis** The minimum work required to separate a gas mixture into its components is equal to the reversible work associated with the mixing process, which is equal to the exergy destruction (or irreversibility) associated with the mixing process since

$$X_{\text{destroyed}} = W_{\text{rev,out}} - W_{\text{act,u}}^{\text{Z}_0} = W_{\text{rev,out}} = T_0 S_{\text{gen}}$$

where  $S_{\text{gen}}$  is the entropy generation associated with the steady-flow mixing process. The entropy change associated with a constant pressure and temperature adiabatic mixing process is determined from

$$\begin{aligned}\bar{s}_{\text{gen}} &= \sum \Delta \bar{s}_i = -R_u \sum y_i \ln y_i = -(8.314 \text{ kJ/kmol} \cdot \text{K})[0.5 \ln(0.5) + 0.5 \ln(0.5)] \\ &= 5.763 \text{ kJ/kmol} \cdot \text{K}\end{aligned}$$

$$M_m = \sum y_i M_i = (0.5)(28 \text{ kg/kmol}) + (0.5)(44 \text{ kg/kmol}) = 36 \text{ kg/kmol}$$

$$s_{\text{gen}} = \frac{\bar{s}_{\text{gen}}}{M_m} = \frac{5.763 \text{ kJ/kmol} \cdot \text{K}}{36 \text{ kg/kmol}} = 0.160 \text{ kJ/kg} \cdot \text{K}$$

$$x_{\text{destroyed}} = T_0 s_{\text{gen}} = (291 \text{ K})(0.160 \text{ kJ/kg} \cdot \text{K}) = \mathbf{46.6 \text{ kJ/kg}}$$

**13-95** A mixture of carbon dioxide, nitrogen, and oxygen is compressed isothermally. The required work is to be determined.

**Assumptions** 1 Nitrogen, oxygen, and carbon dioxide are ideal gases. 2 The process is reversible.

**Properties** The mole numbers of nitrogen, oxygen, and carbon dioxide are 28.0, 32.0, and 44.0 kg/kmol, respectively (Table A-1).

**Analysis** The mole fractions are

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{total}}} = \frac{1 \text{ kmol}}{2.3 \text{ kmol}} = 0.4348$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{total}}} = \frac{1 \text{ kmol}}{2.3 \text{ kmol}} = 0.4348$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{total}}} = \frac{0.3 \text{ kmol}}{2.3 \text{ kmol}} = 0.1304$$

The gas constant for this mixture is then

$$\begin{aligned} R &= \frac{R_u}{y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{N}_2} M_{\text{N}_2} + y_{\text{O}_2} M_{\text{O}_2}} \\ &= \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{(0.4348 \times 44 + 0.4348 \times 28 + 0.1304 \times 32) \text{ kg/kmol}} = 0.2343 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The mass of this mixture of gases is

$$m = N_{\text{CO}_2} M_{\text{CO}_2} + N_{\text{N}_2} M_{\text{N}_2} + N_{\text{O}_2} M_{\text{O}_2} = 1 \times 44 + 1 \times 28 + 0.3 \times 32 = 81.6 \text{ kg}$$

Noting that  $Pv = RT$  for an ideal gas, the work done for this process is then

$$\begin{aligned} W_{\text{out}} &= m \int_1^2 P d\nu = mRT \int_1^2 \frac{d\nu}{\nu} = mRT \ln \frac{\nu_2}{\nu_1} = mRT \ln \frac{P_1}{P_2} \\ &= (81.6 \text{ kg})(0.2343 \text{ kJ/kg} \cdot \text{K})(300 \text{ K}) \ln \frac{10 \text{ kPa}}{100 \text{ kPa}} \\ &= \mathbf{-13,200 \text{ kJ}} \end{aligned}$$

The negative sign shows that the work is done on the system.

**13-96E** A mixture of nitrogen and oxygen is expanded isothermally. The work produced is to be determined.

**Assumptions** 1 Nitrogen and oxygen are ideal gases. 2 The process is reversible.

**Properties** The mole numbers of nitrogen and oxygen are 28.0 and 32.0 lbm/lbmol, respectively (Table A-1E).

**Analysis** The mole fractions are

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{total}}} = \frac{0.1 \text{ lbmol}}{0.3 \text{ lbmol}} = 0.3333$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{total}}} = \frac{0.2 \text{ kmol}}{0.3 \text{ kmol}} = 0.6667$$

The gas constant for this mixture is then

$$R = \frac{R_u}{y_{\text{N}_2} M_{\text{N}_2} + y_{\text{O}_2} M_{\text{O}_2}}$$

$$= \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{(0.3333 \times 28 + 0.6667 \times 32) \text{ lbm/lbmol}}$$

$$= 0.06475 \text{ Btu/lbm} \cdot \text{R}$$

$$= (0.06475 \text{ Btu/lbm} \cdot \text{R}) \left( \frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right)$$

$$= 0.3499 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R}$$

The mass of this mixture of gases is

$$m = N_{\text{N}_2} M_{\text{N}_2} + N_{\text{O}_2} M_{\text{O}_2} = 0.1 \times 28 + 0.2 \times 32 = 9.2 \text{ lbm}$$

The temperature of the mixture is

$$T_1 = \frac{P_1 \nu_1}{mR} = \frac{(300 \text{ psia})(5 \text{ ft}^3)}{(9.2 \text{ lbm})(0.3499 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})} = 466.0 \text{ R}$$

Noting that  $P\nu = RT$  for an ideal gas, the work done for this process is then

$$W_{\text{out}} = m \int_1^2 P d\nu = mRT \int_1^2 \frac{d\nu}{\nu} = mRT \ln \frac{\nu_2}{\nu_1}$$

$$= (9.2 \text{ lbm})(0.06475 \text{ Btu/lbm} \cdot \text{R})(466 \text{ R}) \ln \frac{10 \text{ ft}^3}{5 \text{ ft}^3}$$

$$= \mathbf{192.4 \text{ Btu}}$$

**13-97** The specific heat ratio and an apparent molecular weight of a mixture of ideal gases are given. The work required to compress this mixture isentropically in a closed system is to be determined.

**Analysis** For an isentropic process of an ideal gas with constant specific heats, the work is expressed as

$$\begin{aligned} w_{\text{out}} &= \int_1^2 P d\nu = P_1 \nu_1^k \int_1^2 \nu^{-k} d\nu = \frac{P_1 \nu_1^k}{1-k} (\nu_2^{1-k} - \nu_1^{1-k}) \\ &= \frac{P_1 \nu_1^k}{1-k} (\nu_2^{1-k} - \nu_1^{1-k}) = \frac{P_1 \nu_1^k}{1-k} \left[ \left( \frac{\nu_2}{\nu_1} \right)^{1-k} - 1 \right] \end{aligned}$$

since  $P_1 \nu_1^k = P_2 \nu_2^k$  for an isentropic process. Also,

$$\begin{aligned} P_1 \nu_1 &= RT_1 \\ (\nu_2 / \nu_1)^k &= P_1 / P_2 \end{aligned}$$

Substituting, we obtain

$$\begin{aligned} w_{\text{out}} &= \frac{R_u T_1}{M(1-k)} \left[ \left( \frac{P_2}{P_1} \right)^{(k-1)/k} - 1 \right] \\ &= \frac{(8.314)(293)}{(32)(1-1.35)} \left[ \left( \frac{1000}{100} \right)^{(1.35-1)/1.35} - 1 \right] \\ &= \mathbf{-177.6 \text{ kJ/kg}} \end{aligned}$$

The negative sign shows that the work is done on the system.

**13-98** A mixture of gases is assembled by filling an evacuated tank with neon, oxygen, and nitrogen added one after another. The mass of each constituent in the resulting mixture, the apparent molecular weight of the mixture, and the fraction of the tank volume occupied by nitrogen are to be determined.

**Properties** The molar masses of Ne, O<sub>2</sub>, and N<sub>2</sub> are 20.18, 32.0, 28.0 kg/kmol, respectively and the gas constants are 0.4119, 0.2598, and 0.2968 kJ/kg·K, respectively (Table A-1).

**Analysis** The mass of each constituent is calculated by

$$m_{\text{Ne}} = \frac{P_{\text{Ne}} \nu_m}{R_{\text{Ne}} T} = \frac{(35 \text{ kPa})(0.15 \text{ m}^3)}{(0.4119 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(333 \text{ K})} = \mathbf{0.03828 \text{ kg}}$$

$$m_{\text{O}_2} = \frac{P_{\text{O}_2} \nu_m}{R_{\text{O}_2} T} = \frac{(70 \text{ kPa})(0.15 \text{ m}^3)}{(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(333 \text{ K})} = \mathbf{0.1214 \text{ kg}}$$

$$m_{\text{N}_2} = \frac{P_{\text{N}_2} \nu_m}{R_{\text{N}_2} T} = \frac{(35 \text{ kPa})(0.15 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(333 \text{ K})} = \mathbf{0.05312 \text{ kg}}$$

|                                                                                            |
|--------------------------------------------------------------------------------------------|
| 35 kPa Ne<br>70 kPa O <sub>2</sub><br>35 kPa N <sub>2</sub><br>0.15 m <sup>3</sup><br>60°C |
|--------------------------------------------------------------------------------------------|

The mole number of each constituent is

$$N_{\text{Ne}} = \frac{m_{\text{Ne}}}{M_{\text{Ne}}} = \frac{0.03828 \text{ kg}}{20.18 \text{ kg/kmol}} = 0.001896 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.1214 \text{ kg}}{32.0 \text{ kg/kmol}} = 0.003794 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{0.05312 \text{ kg}}{28.0 \text{ kg/kmol}} = 0.001897 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{(0.03828 + 0.1214 + 0.05312) \text{ kg}}{(0.001896 + 0.003794 + 0.001897) \text{ kmol}} = \frac{0.2128 \text{ kg}}{0.007586 \text{ kmol}} = \mathbf{28.05 \text{ kg/kmol}}$$

The mole fraction of nitrogen is

$$y_{\text{N}_2} = \frac{P_{\text{N}_2}}{P_m} = \frac{35 \text{ kPa}}{140 \text{ kPa}} = 0.25$$

The partial volume occupied by nitrogen is then

$$\nu_{\text{N}_2} = y_{\text{N}_2} \nu_m = (0.25)(0.15 \text{ m}^3) = \mathbf{0.0375 \text{ m}^3}$$

**13-99** A portion of the gas in the previous problem is placed in a spring-loaded piston-cylinder device. The device is now heated until the pressure rises to a specified value. The total work and heat transfer for this process are to be determined.

**Properties** The molar masses of Ne, O<sub>2</sub>, and N<sub>2</sub> are 20.18, 32.0, 28.0 kg/kmol, respectively and the gas constants are 0.4119, 0.2598, and 0.2968 kJ/kg·K, respectively (Table A-1). The constant-volume specific volumes are 0.6179, 0.658, and 0.743 kJ/kg·K, respectively (Table A-2a).

**Analysis** Using the data from the previous problem, the mass fractions are

$$mf_{\text{Ne}} = \frac{m_{\text{Ne}}}{m_m} = \frac{0.03828 \text{ kg}}{0.2128 \text{ kg}} = 0.1799$$

$$mf_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{0.1214 \text{ kg}}{0.2128 \text{ kg}} = 0.5705$$

$$mf_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{0.05312 \text{ kg}}{0.2128 \text{ kg}} = 0.2496$$

The constant-volume specific heat of the mixture is determined from

$$\begin{aligned} c_v &= mf_{\text{Ne}} c_{v,\text{Ne}} + mf_{\text{O}_2} c_{v,\text{O}_2} + mf_{\text{N}_2} c_{v,\text{N}_2} \\ &= 0.1799 \times 0.6179 + 0.5705 \times 0.658 + 0.2496 \times 0.743 \\ &= 0.672 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.05 \text{ kg/kmol}} = 0.2964 \text{ kJ/kg} \cdot \text{K}$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2964 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.2384 \text{ kg}$$

Noting that the pressure changes linearly with volume, the final volume is determined by linear interpolation to be

$$\frac{500 - 200}{1000 - 200} = \frac{V_2 - 0.1}{1.0 - 0.1} \longrightarrow V_2 = 0.4375 \text{ m}^3$$

The final temperature is

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(500 \text{ kPa})(0.4375 \text{ m}^3)}{(0.2384 \text{ kg})(0.2964 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 3096 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(500 + 200) \text{ kPa}}{2} (0.4375 - 0.1) \text{ m}^3 = \mathbf{118 \text{ kJ}}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v (T_2 - T_1) = 118 + (0.2384 \text{ kg})(0.672 \text{ kJ/kg} \cdot \text{K})(3096 - 283) \text{ K} = \mathbf{569 \text{ kJ}}$$

**13-100** A spring-loaded piston-cylinder device is filled with a mixture of nitrogen and carbon dioxide whose mass fractions are given. The gas is heated until the volume has doubled. The total work and heat transfer for this process are to be determined.

**Properties** The molar masses of  $N_2$  and  $CO_2$  are 28.0 and 44.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at room temperature are 0.743 and 0.657 kJ/kg·K, respectively (Table A-2a).

**Analysis** We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{70 \text{ kg}}{28 \text{ kg/kmol}} = 2.5 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{30 \text{ kg}}{44 \text{ kg/kmol}} = 0.6818 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{N_2} + N_{CO_2} = 2.5 + 0.6818 = 3.1818 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{3.1818 \text{ kmol}} = 31.43 \text{ kg/kmol}$$

The constant-volume specific heat of the mixture is determined from

$$c_v = mf_{N_2} c_{v,N_2} + mf_{CO_2} c_{v,CO_2} = 0.70 \times 0.743 + 0.30 \times 0.657 = 0.717 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{31.43 \text{ kg/kmol}} = 0.2645 \text{ kJ/kg} \cdot \text{K}$$

Noting that the pressure changes linearly with volume, the initial volume is determined by linear interpolation using the data of the previous problem to be

$$\frac{400 - 200}{1000 - 200} = \frac{V_1 - 0.1}{1.0 - 0.1} \longrightarrow V_1 = 0.325 \text{ m}^3$$

The final volume is

$$V_2 = 2V_1 = 2(0.325 \text{ m}^3) = 0.650 \text{ m}^3$$

The final pressure is similarly determined by linear interpolation using the data of the previous problem to be

$$\frac{P_2 - 200}{1000 - 200} = \frac{0.650 - 0.1}{1.0 - 0.1} \longrightarrow P_2 = 689 \text{ kPa}$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(400 \text{ kPa})(0.325 \text{ m}^3)}{(0.2645 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(303 \text{ K})} = 1.622 \text{ kg}$$

The final temperature is

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(689 \text{ kPa})(0.650 \text{ m}^3)}{(1.622 \text{ kg})(0.2645 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 1044 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(400 + 689) \text{ kPa}}{2} (0.650 - 0.325) \text{ m}^3 = \mathbf{177 \text{ kJ}}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v (T_2 - T_1) = 177 + (1.622 \text{ kg})(0.717 \text{ kJ/kg} \cdot \text{K})(1044 - 303) \text{ K} = \mathbf{1039 \text{ kJ}}$$

**13-101** A spring-loaded piston-cylinder device is filled with a mixture of nitrogen and carbon dioxide whose mass fractions are given. The gas is heated until the pressure has tripled. The total work and heat transfer for this process are to be determined.

**Properties** The molar masses of  $N_2$  and  $CO_2$  are 28.0 and 44.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at room temperature are 0.743 and 0.657 kJ/kg·K, respectively (Table A-2a).

**Analysis** We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{70 \text{ kg}}{28 \text{ kg/kmol}} = 2.5 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{30 \text{ kg}}{44 \text{ kg/kmol}} = 0.6818 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{N_2} + N_{CO_2} = 2.5 + 0.6818 = 3.1818 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{3.1818 \text{ kmol}} = 31.43 \text{ kg/kmol}$$

The constant-volume specific heat of the mixture is determined from

$$c_v = mf_{N_2} c_{v,N_2} + mf_{CO_2} c_{v,CO_2} = 0.70 \times 0.743 + 0.30 \times 0.657 = 0.717 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{31.43 \text{ kg/kmol}} = 0.2645 \text{ kJ/kg} \cdot \text{K}$$

Noting that the pressure changes linearly with volume, the initial volume is determined by linear interpolation using the data of the earlier problem to be

$$\frac{400 - 200}{1000 - 200} = \frac{V_1 - 0.1}{1.0 - 0.1} \longrightarrow V_1 = 0.325 \text{ m}^3$$

The final pressure is

$$P_2 = 3P_1 = 3(400 \text{ kPa}) = 1200 \text{ kPa}$$

The final volume is similarly determined by linear interpolation using the data of the earlier problem to be

$$\frac{1200 - 200}{1000 - 200} = \frac{V_2 - 0.1}{1.0 - 0.1} \longrightarrow V_2 = 1.225 \text{ m}^3$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(400 \text{ kPa})(0.325 \text{ m}^3)}{(0.2645 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(303 \text{ K})} = 1.622 \text{ kg}$$

The final temperature is

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(1200 \text{ kPa})(1.225 \text{ m}^3)}{(1.622 \text{ kg})(0.2645 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 3426 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(400 + 1200) \text{ kPa}}{2} (1.225 - 0.325) \text{ m}^3 = \mathbf{720 \text{ kJ}}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v (T_2 - T_1) = 720 + (1.622 \text{ kg})(0.717 \text{ kJ/kg} \cdot \text{K})(3426 - 303) \text{ K} = \mathbf{4352 \text{ kJ}}$$

**13-102** The masses of components of a gas mixture are given. This mixture is expanded in an adiabatic, steady-flow turbine of specified isentropic efficiency. The second law efficiency and the exergy destruction during this expansion process are to be determined.

**Assumptions** All gases will be modeled as ideal gases with constant specific heats.

**Properties** The molar masses of  $O_2$ ,  $CO_2$ , and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 0.918, 0.846, and 5.1926 kJ/kg·K, respectively (Table A-2a).

**Analysis** The total mass of the mixture is

$$m_m = m_{O_2} + m_{CO_2} + m_{He} = 0.1 + 1 + 0.5 = 1.6 \text{ kg}$$

The mole numbers of each component are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{0.1 \text{ kg}}{32 \text{ kg/kmol}} = 0.003125 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.02273 \text{ kmol}$$

$$N_{He} = \frac{m_{He}}{M_{He}} = \frac{0.5 \text{ kg}}{4 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{O_2} + N_{CO_2} + N_{He} = 0.003125 + 0.02273 + 0.125 = 0.15086 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1.6 \text{ kg}}{0.15086 \text{ kmol}} = 10.61 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{10.61 \text{ kg/kmol}} = 0.7836 \text{ kJ/kg} \cdot \text{K}$$

The mass fractions are

$$mf_{O_2} = \frac{m_{O_2}}{m_m} = \frac{0.1 \text{ kg}}{1.6 \text{ kg}} = 0.0625$$

$$mf_{CO_2} = \frac{m_{CO_2}}{m_m} = \frac{1 \text{ kg}}{1.6 \text{ kg}} = 0.625$$

$$mf_{He} = \frac{m_{He}}{m_m} = \frac{0.5 \text{ kg}}{1.6 \text{ kg}} = 0.3125$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{O_2} c_{p,O_2} + mf_{CO_2} c_{p,CO_2} + mf_{He} c_{p,He} \\ &= 0.0625 \times 0.918 + 0.625 \times 0.846 + 0.3125 \times 5.1926 \\ &= 2.209 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 2.209 - 0.7836 = 1.425 \text{ kJ/kg} \cdot \text{K}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{2.209}{1.425} = 1.550$$

The temperature at the end of the expansion for the isentropic process is

$$T_{2s} = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (600 \text{ K}) \left( \frac{100 \text{ kPa}}{1000 \text{ kPa}} \right)^{0.55/1.55} = 265 \text{ K}$$

Using the definition of turbine isentropic efficiency, the actual outlet temperature is

$$T_2 = T_1 - \eta_{\text{turb}} (T_1 - T_{2s}) = (600 \text{ K}) - (0.90)(600 - 265) = 299 \text{ K}$$

The entropy change of the gas mixture is

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (2.209) \ln \frac{299}{600} - (0.7836) \ln \frac{100}{1000} = 0.2658 \text{ kJ/kg} \cdot \text{K}$$

The actual work produced is

$$w_{\text{out}} = h_1 - h_2 = c_p (T_1 - T_2) = (2.209 \text{ kJ/kg} \cdot \text{K})(600 - 299) \text{ K} = 665 \text{ kJ/kg}$$

The reversible work output is

$$w_{\text{rev,out}} = h_1 - h_2 - T_0 (s_1 - s_2) = 665 \text{ kJ/kg} - (298 \text{ K})(-0.2658 \text{ kJ/kg} \cdot \text{K}) = 744 \text{ kJ/kg}$$

The second-law efficiency and the exergy destruction are then

$$\eta_{\text{II}} = \frac{w_{\text{out}}}{w_{\text{rev,out}}} = \frac{665}{744} = \mathbf{0.894}$$

$$x_{\text{dest}} = w_{\text{rev,out}} - w_{\text{out}} = 744 - 665 = \mathbf{79 \text{ kJ/kg}}$$

**13-103** The masses, pressures, and temperatures of the constituents of a gas mixture in a tank are given. Heat is transferred to the tank. The final pressure of the mixture and the heat transfer are to be determined.

**Assumptions** He is an ideal gas and O<sub>2</sub> is a nonideal gas.

**Properties** The molar masses of He and O<sub>2</sub> are 4.0 and 32.0 kg/kmol. (Table A-1)

**Analysis** (a) The number of moles of each gas is

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{4 \text{ kg}}{4.0 \text{ kg/kmol}} = 1 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{8 \text{ kg}}{32 \text{ kg/kmol}} = 0.25 \text{ kmol}$$

$$N_m = N_{\text{He}} + N_{\text{O}_2} = 1 \text{ kmol} + 0.25 \text{ kmol} = 1.25 \text{ kmol}$$

Then the partial volume of each gas and the volume of the tank are

$$\text{He: } \nu_{\text{He}} = \frac{N_{\text{He}} R_u T_1}{P_{m,1}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(170 \text{ K})}{7000 \text{ kPa}} = 0.202 \text{ m}^3$$

$$\text{O}_2: \left. \begin{aligned} P_{R_1} &= \frac{P_{m,1}}{P_{\text{cr},\text{O}_2}} = \frac{7}{5.08} = 1.38 \\ T_{R_1} &= \frac{T_1}{T_{\text{cr},\text{O}_2}} = \frac{170}{154.8} = 1.10 \end{aligned} \right\} Z_1 = 0.53 \quad (\text{Fig. A-15})$$

$$\nu_{\text{O}_2} = \frac{Z N_{\text{O}_2} R_u T_1}{P_{m,1}} = \frac{(0.53)(0.25 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(170 \text{ K})}{7000 \text{ kPa}} = 0.027 \text{ m}^3$$

$$\nu_{\text{tank}} = \nu_{\text{He}} + \nu_{\text{O}_2} = 0.202 \text{ m}^3 + 0.027 \text{ m}^3 = 0.229 \text{ m}^3$$

The partial pressure of each gas and the total final pressure is

$$\text{He: } P_{\text{He},2} = \frac{N_{\text{He}} R_u T_2}{\nu_{\text{tank}}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(220 \text{ K})}{0.229 \text{ m}^3} = 7987 \text{ kPa}$$

$$\text{O}_2: \left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{\text{cr},\text{O}_2}} = \frac{220}{154.8} = 1.42 \\ \nu_{R,\text{O}_2} &= \frac{\bar{\nu}_{\text{O}_2}}{R_u T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} = \frac{\nu_m / N_{\text{O}_2}}{R_u T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} \\ &= \frac{(0.229 \text{ m}^3)/(0.25 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(154.8 \text{ K})/(5080 \text{ kPa})} = 3.616 \end{aligned} \right\} P_R = 0.39 \quad (\text{Fig. A-15})$$

$$P_{\text{O}_2} = (P_R P_{\text{cr}})_{\text{O}_2} = (0.39)(5080 \text{ kPa}) = 1981 \text{ kPa} = 1.981 \text{ MPa}$$

$$P_{m,2} = P_{\text{He}} + P_{\text{O}_2} = 7.987 \text{ MPa} + 1.981 \text{ MPa} = \mathbf{9.97 \text{ MPa}}$$

(b) We take both gases as the system. No work or mass crosses the system boundary, therefore this is a closed system with no work interactions. Then the energy balance for this closed system reduces to

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$Q_{\text{in}} = \Delta U = \Delta U_{\text{He}} + \Delta U_{\text{O}_2}$$

$$\text{He: } \Delta U_{\text{He}} = m c_v (T_m - T_1) = (4 \text{ kg})(3.1156 \text{ kJ/kg} \cdot \text{K})(220 - 170) \text{ K} = 623.1 \text{ kJ}$$

O<sub>2</sub>:

$$\left. \begin{array}{l} T_{R_1} = 1.10 \\ P_{R_1} = 1.38 \end{array} \right\} Z_{h_1} = 2.2$$

$$\left. \begin{array}{l} T_{R_2} = 1.42 \\ P_{R_2} = \frac{9.97}{5.08} = 1.963 \end{array} \right\} Z_{h_2} = 1.2 \quad (\text{Fig. A-29})$$

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= R_u T_{cr} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314 \text{ kJ/kmol} \cdot \text{K})(154.8 \text{ K})(2.2 - 1.2) + (6404 - 4949) \text{ kJ/kmol} = 2742 \text{ kJ/kmol} \end{aligned}$$

Also,

$$P_{\text{He},1} = \frac{N_{\text{He}} R_u T_1}{V_{\text{tank}}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(170 \text{ K})}{0.229 \text{ m}^3} = 6,172 \text{ kPa}$$

$$P_{\text{O}_2,1} = P_{m,1} - P_{\text{He},1} = 7000 \text{ kPa} - 6172 \text{ kPa} = 828 \text{ kPa}$$

Thus,

$$\begin{aligned} \Delta U_{\text{O}_2} &= N_{\text{O}_2} (\bar{h}_2 - \bar{h}_1) - (P_2 V_2 - P_1 V_1) = N_{\text{O}_2} (\bar{h}_2 - \bar{h}_1) - (P_{\text{O}_2,2} - P_{\text{O}_2,1}) V_{\text{tank}} \\ &= (0.25 \text{ kmol})(2742 \text{ kJ/kmol}) - (1981 - 828)(0.229) \text{ kPa} \cdot \text{m}^3 = 421.5 \text{ kJ} \end{aligned}$$

Substituting,

$$Q_{\text{in}} = 623.1 \text{ kJ} + 421.5 \text{ kJ} = \mathbf{1045 \text{ kJ}}$$

**13-104** A mixture of carbon dioxide and methane expands through a turbine. The power produced by the mixture is to be determined using ideal gas approximation and Kay's rule.

**Assumptions** The expansion process is reversible and adiabatic (isentropic).

**Properties** The molar masses of  $\text{CO}_2$  and  $\text{CH}_4$  are 44.0 and 16.0 kg/kmol and respectively. The critical properties are 304.2 K, 7390 kPa for  $\text{CO}_2$  and 191.1 K and 4640 kPa for  $\text{CH}_4$  (Table A-1).

**Analysis** The molar mass of the mixture is determined to be

$$M_m = y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{CH}_4} M_{\text{CH}_4} = (0.60)(44) + (0.40)(16) = 32.80 \text{ kg/kmol}$$

The gas constant is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol}\cdot\text{K}}{32.8 \text{ kg/kmol}} = 0.2533 \text{ kJ/kg}\cdot\text{K}$$

The mass fractions are

$$\text{mf}_{\text{CO}_2} = y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m} = (0.60) \frac{44 \text{ kg/kmol}}{32.8 \text{ kg/kmol}} = 0.8049$$

$$\text{mf}_{\text{CH}_4} = y_{\text{CH}_4} \frac{M_{\text{CH}_4}}{M_m} = (0.40) \frac{16 \text{ kg/kmol}}{32.8 \text{ kg/kmol}} = 0.1951$$

**Ideal gas solution:**

Using Dalton's law to find partial pressures, the entropies at the initial state are determined from EES to be:

$$T = 1600 \text{ K}, P = (0.60 \times 800) = 480 \text{ kPa} \longrightarrow s_{\text{CO}_2,1} = 6.424 \text{ kJ/kg}\cdot\text{K}$$

$$T = 1600 \text{ K}, P = (0.40 \times 800) = 320 \text{ kPa} \longrightarrow s_{\text{CH}_4,1} = 17.188 \text{ kJ/kg}\cdot\text{K}$$

The final state entropies cannot be determined at this point since the final temperature is not known. However, for an isentropic process, the entropy change is zero and the final temperature may be determined from

$$\begin{aligned} \Delta s_{\text{total}} &= \text{mf}_{\text{CO}_2} \Delta s_{\text{CO}_2} + \text{mf}_{\text{CH}_4} \Delta s_{\text{CH}_4} \\ 0 &= \text{mf}_{\text{CO}_2} (s_{\text{CO}_2,2} - s_{\text{CO}_2,1}) + \text{mf}_{\text{CH}_4} (s_{\text{CH}_4,2} - s_{\text{CH}_4,1}) \end{aligned}$$

The solution is obtained using EES to be

$$T_2 = 1243 \text{ K}$$

The initial and final enthalpies and the changes in enthalpy are (from EES)

$$\begin{aligned} T_1 = 1600 \text{ K} \longrightarrow \begin{aligned} h_{\text{CO}_2,1} &= -7408 \text{ kJ/kg} \\ u_{\text{CH}_4,1} &= 747.4 \text{ kJ/kg} \end{aligned} & \quad T_2 = 1243 \text{ K} \longrightarrow \begin{aligned} h_{\text{CO}_2,2} &= -7877 \text{ kJ/kg} \\ u_{\text{CH}_4,2} &= -1136 \text{ kJ/kg} \end{aligned} \end{aligned}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$\dot{Q}_{\text{in}} - \dot{W}_{\text{out}} = \dot{m} \Delta h_m \longrightarrow \dot{W}_{\text{out}} = -\dot{m} \Delta h_m$$

where

$$\begin{aligned} \Delta h_m &= \text{mf}_{\text{CO}_2} (h_{\text{CO}_2,2} - h_{\text{CO}_2,1}) + \text{mf}_{\text{CH}_4} (h_{\text{CH}_4,2} - h_{\text{CH}_4,1}) \\ &= (0.8049)[(-7877) - (-7408)] + (0.1951)[(-1136) - (747.4)] = -745.9 \text{ kJ/kg} \end{aligned}$$

The mass flow rate is

$$\dot{m} = \frac{P_1 \dot{V}_1}{RT_1} = \frac{(800 \text{ kPa})(0.010 \text{ m}^3/\text{s})}{(0.2533 \text{ kJ/kg}\cdot\text{K})(1600 \text{ K})} = 0.01974 \text{ kg/s}$$

$$\text{Substituting, } \dot{W}_{\text{out}} = \dot{m} \Delta h_m = -(0.01974)(-745.9 \text{ kJ/kg}) = \mathbf{14.72 \text{ kW}}$$

**Kay's rule solution:**

The critical temperature and pressure of the mixture is

$$T_{cr} = y_{CO_2} T_{cr,CO_2} + y_{CH_4} T_{cr,CH_4} = (0.60)(304.2 \text{ K}) + (0.40)(191.1 \text{ K}) = 259.0 \text{ K}$$

$$P_{cr} = y_{CO_2} P_{cr,CO_2} + y_{CH_4} P_{cr,CH_4} = (0.60)(7390 \text{ kPa}) + (0.40)(4640 \text{ kPa}) = 6290 \text{ kPa}$$

State 1 properties:

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{1600 \text{ K}}{259.0 \text{ K}} = 6.178 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{800 \text{ kPa}}{6290 \text{ kPa}} = 0.127 \end{aligned} \right\} \begin{aligned} Z_1 &= 1.002 \\ Z_{h1} &= -0.01025 \quad (\text{from EES}) \\ Z_{s1} &= 0.0001277 \end{aligned}$$

$$\Delta h_1 = Z_{h1} R T_{cr} = (-0.01025)(0.2533 \text{ kJ/kg.K})(259.0 \text{ K}) = -0.6714 \text{ kJ/kg}$$

$$\begin{aligned} h_1 &= mf_{CO_2} h_{CO_2,1} + mf_{CH_4} h_{CH_4,1} - \Delta h_1 \\ &= (0.8049)(-7408) + (0.1951)(747.1) - (-0.6714) = -5813 \text{ kJ/kg} \end{aligned}$$

$$\Delta s_1 = Z_{s1} R = (0.0001277)(0.2533 \text{ kJ/kg.K}) = 0.00003234 \text{ kJ/kg.K}$$

$$\begin{aligned} s_1 &= mf_{CO_2} s_{CO_2,1} + mf_{CH_4} s_{CH_4,1} - \Delta s_1 \\ &= (0.8049)(6.424) + (0.1951)(17.188) - (0.00003234) = 8.529 \text{ kJ/kg.K} \end{aligned}$$

The final state entropies cannot be determined at this point since the final temperature is not known. However, for an isentropic process, the entropy change is zero and the final temperature may be determined from

$$\begin{aligned} \Delta s_{total} &= mf_{CO_2} \Delta s_{CO_2} + mf_{CH_4} \Delta s_{CH_4} \\ 0 &= mf_{CO_2} (s_{CO_2,2} - s_{CO_2,1}) + mf_{CH_4} (s_{CH_4,2} - s_{CH_4,1}) \end{aligned}$$

The solution is obtained using EES to be

$$T_2 = 1243 \text{ K}$$

The initial and final enthalpies and the changes in enthalpy are

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{1243 \text{ K}}{259.0 \text{ K}} = 4.80 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{100 \text{ kPa}}{6290 \text{ kPa}} = 0.016 \end{aligned} \right\} \begin{aligned} Z_{h2} &= -0.00007368 \\ Z_{s2} &= 0.0001171 \end{aligned} \quad (\text{from EES})$$

$$\Delta h_2 = Z_{h2} R T_{cr} = (-0.00007368)(0.2533 \text{ kJ/kg.K})(259.0 \text{ K}) = -0.04828 \text{ kJ/kg}$$

$$\begin{aligned} h_2 &= mf_{CO_2} h_{CO_2,2} + mf_{CH_4} h_{CH_4,2} - \Delta h_2 \\ &= (0.8049)(-7877) + (0.1951)(-1136) - (-0.4828) = -6559 \text{ kJ/kg} \end{aligned}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$\dot{Q}_{in} - \dot{W}_{out} = \dot{m} \Delta h_m \longrightarrow \dot{W}_{out} = -\dot{m}(h_2 - h_1)$$

where the mass flow rate is

$$\dot{m} = \frac{P_1 \dot{V}_1}{Z_1 R T_1} = \frac{(800 \text{ kPa})(0.010 \text{ m}^3/\text{s})}{(1.002)(0.2533 \text{ kJ/kg.K})(1600 \text{ K})} = 0.01970 \text{ kg/s}$$

Substituting,

$$\dot{W}_{out} = -(0.01970 \text{ kg/s})[(-6559) - (-5813) \text{ kJ/kg}] = \mathbf{14.71 \text{ kW}}$$

**13-105 EES** A program is to be written to determine the mole fractions of the components of a mixture of three gases with known molar masses when the mass fractions are given, and to determine the mass fractions of the components when the mole fractions are given. Also, the program is to be run for a sample case.

**Analysis** The problem is solved using EES, and the solution is given below.

```

## Fundamentals of Engineering (FE) Exam Problems

**13-107** An ideal gas mixture whose apparent molar mass is 36 kg/kmol consists of nitrogen  $N_2$  and three other gases. If the mole fraction of nitrogen is 0.30, its mass fraction is

- (a) 0.15                      (b) 0.23                      (c) 0.30                      (d) 0.39                      (e) 0.70

*Answer* (b) 0.23

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
M_mix=36 "kg/kmol"
M_N2=28 "kg/kmol"
y_N2=0.3
mf_N2=(M_N2/M_mix)*y_N2
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_mf = y_N2 "Taking mass fraction to be equal to mole fraction"
W2_mf= y_N2*(M_mix/M_N2) "Using the molar mass ratio backwards"
W3_mf= 1-mf_N2 "Taking the complement of the mass fraction"
```

**13-108** An ideal gas mixture consists of 2 kmol of  $N_2$  and 6 kmol of  $CO_2$ . The mass fraction of  $CO_2$  in the mixture is

- (a) 0.175                      (b) 0.250                      (c) 0.500                      (d) 0.750                      (e) 0.825

*Answer* (e) 0.825

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
N1=2 "kmol"
N2=6 "kmol"
N_mix=N1+N2
MM1=28 "kg/kmol"
MM2=44 "kg/kmol"
m_mix=N1*MM1+N2*MM2
mf2=N2*MM2/m_mix
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_mf = N2/N_mix "Using mole fraction"
W2_mf = 1-mf2 "The wrong mass fraction"
```

**13-109** An ideal gas mixture consists of 2 kmol of  $N_2$  and 4 kmol of  $CO_2$ . The apparent gas constant of the mixture is

- (a) 0.215 kJ/kg·K      (b) 0.225 kJ/kg·K      (c) 0.243 kJ/kg·K      (d) 0.875 kJ/kg·K  
 (e) 1.24 kJ/kg·K

*Answer* (a) 0.215 kJ/kg·K

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Ru=8.314 "kJ/kmol.K"
N1=2 "kmol"
N2=4 "kmol"
MM1=28 "kg/kmol"
MM2=44 "kg/kmol"
R1=Ru/MM1
R2=Ru/MM2
N_mix=N1+N2
y1=N1/N_mix
y2=N2/N_mix
MM_mix=y1*MM1+y2*MM2
R_mix=Ru/MM_mix
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Rmix =(R1+R2)/2 "Taking the arithmetic average of gas constants"
W2_Rmix= y1*R1+y2*R2 "Using wrong relation for Rmixture"
```

**13-110** A rigid tank is divided into two compartments by a partition. One compartment contains 3 kmol of  $N_2$  at 600 kPa pressure and the other compartment contains 7 kmol of  $CO_2$  at 200 kPa. Now the partition is removed, and the two gases form a homogeneous mixture at 300 kPa. The partial pressure of  $N_2$  in the mixture is

- (a) 75 kPa                      (b) 90 kPa                      (c) 150 kPa                      (d) 175 kPa                      (e) 225 kPa

Answer (b) 90 kPa

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1 = 600 "kPa"
P2 = 200 "kPa"
P_mix=300 "kPa"

### 13-117 ... 13-119 Design and Essay Problem

## Chapter 14

# GAS-VAPOR MIXTURES AND AIR CONDITIONING

### Dry and Atmospheric Air, Specific and Relative Humidity

**14-1C** Yes; by cooling the air at constant pressure.

**14-2C** Yes.

**14-3C** Specific humidity will decrease but relative humidity will increase.

**14-4C** Dry air does not contain any water vapor, but atmospheric air does.

**14-5C** Yes, the water vapor in the air can be treated as an ideal gas because of its very low partial pressure.

**14-6C** The partial pressure of the water vapor in atmospheric air is called vapor pressure.

**14-7C** The same. This is because water vapor behaves as an ideal gas at low pressures, and the enthalpy of an ideal gas depends on temperature only.

**14-8C** Specific humidity is the amount of water vapor present in a unit mass of dry air. Relative humidity is the ratio of the actual amount of vapor in the air at a given temperature to the maximum amount of vapor air can hold at that temperature.

**14-9C** The specific humidity will remain constant, but the relative humidity will decrease as the temperature rises in a well-sealed room.

**14-10C** The specific humidity will remain constant, but the relative humidity will decrease as the temperature drops in a well-sealed room.

**14-11C** A tank that contains moist air at 3 atm is located in moist air that is at 1 atm. The driving force for moisture transfer is the vapor pressure difference, and thus it is possible for the water vapor to flow into the tank from surroundings if the vapor pressure in the surroundings is greater than the vapor pressure in the tank.

**14-12C** Insulations on *chilled water lines* are always wrapped with *vapor barrier jackets* to eliminate the possibility of vapor entering the insulation. This is because moisture that migrates through the insulation to the cold surface will condense and remain there indefinitely with no possibility of vaporizing and moving back to the outside.

**14-13C** When the temperature, total pressure, and the relative humidity are given, the vapor pressure can be determined from the psychrometric chart or the relation  $P_v = \phi P_{\text{sat}}$  where  $P_{\text{sat}}$  is the saturation (or boiling) pressure of water at the specified temperature and  $\phi$  is the relative humidity.

**14-14E** Humid air is expanded in an isentropic nozzle. The amount of water vapor that has condensed during the process is to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Properties** The specific heat ratio of air at room temperature is  $k = 1.4$  (Table A-2a). The saturation properties of water are to be obtained from water tables.

**Analysis** Since the mole fraction of the water vapor in this mixture is very small,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (860 \text{ R}) \left( \frac{15 \text{ psia}}{100 \text{ psia}} \right)^{0.4/1.4} = 500 \text{ R}$$

We will assume that the air leaves the nozzle at a relative humidity of 100% (will be verified later). The vapor pressure and specific humidity at the outlet are then

$$P_{v,2} = \phi_2 P_{g,2} = \phi_2 P_{\text{sat @ } 40^\circ\text{F}} = (1.0)(0.12173 \text{ psia}) = 0.1217 \text{ psia}$$

$$\omega_2 = \frac{0.622 P_{v,2}}{P - P_{v,2}} = \frac{(0.622)(0.1217 \text{ psia})}{(15 - 0.1217) \text{ psia}} = 0.00509 \text{ lbm H}_2\text{O/lbm dry air}$$

This is less than the inlet specific humidity (0.025 lbm/lbm dry air), the relative humidity at the outlet must be 100% as originally assumed. The amount of liquid formation is then

$$\Delta\omega = \omega_1 - \omega_2 = 0.025 - 0.00509 = \mathbf{0.0199 \text{ lbm H}_2\text{O/lbm dry air}}$$

**14-15** Humid air is compressed in an isentropic compressor. The relative humidity of the air at the compressor outlet is to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Properties** The specific heat ratio of air at room temperature is  $k = 1.4$  (Table A-2a). The saturation properties of water are to be obtained from water tables.

**Analysis** At the inlet,

$$P_{v,1} = \phi_1 P_{g,1} = \phi_1 P_{\text{sat @ } 20^\circ\text{C}} = (0.90)(2.3392 \text{ kPa}) = 2.105 \text{ kPa}$$

$$\omega_2 = \omega_1 = \frac{0.622 P_{v,1}}{P - P_{v,1}} = \frac{(0.622)(2.105 \text{ kPa})}{(100 - 2.105) \text{ kPa}} = 0.0134 \text{ kg H}_2\text{O/kg dry air}$$

Since the mole fraction of the water vapor in this mixture is very small,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (293 \text{ K}) \left( \frac{800 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 531 \text{ K}$$

The saturation pressure at this temperature is

$$P_{g,2} = P_{\text{sat @ } 258^\circ\text{C}} = 4542 \text{ kPa} \quad (\text{from EES})$$

The vapor pressure at the exit is

$$P_{v,2} = \frac{\omega_2 P_2}{\omega_2 + 0.622} = \frac{(0.0134)(800)}{0.0134 + 0.622} = 16.87 \text{ kPa}$$

The relative humidity at the exit is then

$$\phi_2 = \frac{P_{v,2}}{P_{g,2}} = \frac{16.87}{4542} = \mathbf{0.0037 = 0.37\%}$$

**14-16** A tank contains dry air and water vapor at specified conditions. The specific humidity, the relative humidity, and the volume of the tank are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) The specific humidity can be determined from its definition,

$$\omega = \frac{m_v}{m_a} = \frac{0.3 \text{ kg}}{21 \text{ kg}} = \mathbf{0.0143 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The saturation pressure of water at 30°C is

$$P_g = P_{\text{sat @ } 30^\circ\text{C}} = 4.2469 \text{ kPa}$$

Then the relative humidity can be determined from

$$\phi = \frac{\omega P}{(0.622 + \omega)P_g} = \frac{(0.0143)(100 \text{ kPa})}{(0.622 + 0.0143)(4.2469 \text{ kPa})} = \mathbf{52.9\%}$$

(c) The volume of the tank can be determined from the ideal gas relation for the dry air,

$$P_v = \phi P_g = (0.529)(4.2469 \text{ kPa}) = 2.245 \text{ kPa}$$

$$P_a = P - P_v = 100 - 2.245 = 97.755 \text{ kPa}$$

$$\mathcal{V} = \frac{m_a R_a T}{P_a} = \frac{(21 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(303 \text{ K})}{97.755 \text{ kPa}} = \mathbf{18.7 \text{ m}^3}$$

21 kg dry air  
0.3 kg H<sub>2</sub>O vapor  
30°C  
100 kPa

**14-17** A tank contains dry air and water vapor at specified conditions. The specific humidity, the relative humidity, and the volume of the tank are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) The specific humidity can be determined from its definition,

$$\omega = \frac{m_v}{m_a} = \frac{0.3 \text{ kg}}{21 \text{ kg}} = \mathbf{0.0143 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The saturation pressure of water at 24°C is

$$P_g = P_{\text{sat @ } 24^\circ\text{C}} = 2.986 \text{ kPa}$$

Then the relative humidity can be determined from

$$\phi = \frac{\omega P}{(0.622 + \omega)P_g} = \frac{(0.0143)(100 \text{ kPa})}{(0.622 + 0.0143)2.986 \text{ kPa}} = \mathbf{75.2\%}$$

(c) The volume of the tank can be determined from the ideal gas relation for the dry air,

$$P_v = \phi P_g = (0.752)(2.986 \text{ kPa}) = 2.245 \text{ kPa}$$

$$P_a = P - P_v = 100 - 2.245 = 97.755 \text{ kPa}$$

$$\mathcal{V} = \frac{m_a R_a T}{P_a} = \frac{(21 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(297 \text{ K})}{97.755 \text{ kPa}} = \mathbf{18.3 \text{ m}^3}$$

21 kg dry air  
0.3 kg H<sub>2</sub>O vapor  
24°C  
100 kPa

**14-18** A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat}@20^\circ\text{C}} = (0.85)(2.3392 \text{ kPa}) = 1.988 \text{ kPa}$$

$$P_a = P - P_v = 98 - 1.988 = \mathbf{96.01 \text{ kPa}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(1.988 \text{ kPa})}{(98 - 1.988) \text{ kPa}} = \mathbf{0.0129 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \cong c_p T + \omega h_g \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0129)(2537.4 \text{ kJ/kg}) \\ &= \mathbf{52.78 \text{ kJ/kg dry air}} \end{aligned}$$

## Dew-point, Adiabatic Saturation, and Wet-bulb Temperatures

**14-22C** Dew-point temperature is the temperature at which condensation begins when air is cooled at constant pressure.

**14-23C** Andy's. The temperature of his glasses may be below the dew-point temperature of the room, causing condensation on the surface of the glasses.

**14-24C** The outer surface temperature of the glass may drop below the dew-point temperature of the surrounding air, causing the moisture in the vicinity of the glass to condense. After a while, the condensate may start dripping down because of gravity.

**14-25C** When the temperature falls below the dew-point temperature, dew forms on the outer surfaces of the car. If the temperature is below 0°C, the dew will freeze. At very low temperatures, the moisture in the air will freeze directly on the car windows.

**14-26C** When the air is saturated (100% relative humidity).

**14-27C** These two are approximately equal at atmospheric temperatures and pressure.

**14-28** A house contains air at a specified temperature and relative humidity. It is to be determined whether any moisture will condense on the inner surfaces of the windows when the temperature of the window drops to a specified value.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** The vapor pressure  $P_v$  is uniform throughout the house, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.65)(3.1698 \text{ kPa}) = 2.06 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 2.06 \text{ kPa}} = \mathbf{18.0^\circ\text{C}}$$

That is, the moisture in the house air will start condensing when the temperature drops below 18.0°C. Since the windows are at a lower temperature than the dew-point temperature, some moisture **will condense** on the window surfaces.

**14-29** A person wearing glasses enters a warm room at a specified temperature and relative humidity from the cold outdoors. It is to be determined whether the glasses will get fogged.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** The vapor pressure  $P_v$  of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.40)(3.1698 \text{ kPa}) = 1.268 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 1.268 \text{ kPa}} = \mathbf{10.5^\circ\text{C}} \quad (\text{from EES})$$

That is, the moisture in the house air will start condensing when the air temperature drops below  $10.5^\circ\text{C}$ . Since the glasses are at a lower temperature than the dew-point temperature, some moisture will condense on the glasses, and thus they **will get fogged**.

**14-30** A person wearing glasses enters a warm room at a specified temperature and relative humidity from the cold outdoors. It is to be determined whether the glasses will get fogged.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** The vapor pressure  $P_v$  of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.30)(3.1698 \text{ kPa}) = 0.95 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.95 \text{ kPa}} = \mathbf{6.2^\circ\text{C}} \quad (\text{from EES})$$

That is, the moisture in the house air will start condensing when the air temperature drops below  $6.2^\circ\text{C}$ . Since the glasses are at a higher temperature than the dew-point temperature, moisture will not condense on the glasses, and thus they **will not get fogged**.

**14-31E** A woman drinks a cool canned soda in a room at a specified temperature and relative humidity. It is to be determined whether the can will sweat.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** The vapor pressure  $P_v$  of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 80^\circ\text{F} = (0.50)(0.50745 \text{ psia}) = 0.254 \text{ psia}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.254 \text{ psia}} = \mathbf{59.7^\circ\text{F}} \text{ (from EES)}$$

That is, the moisture in the house air will start condensing when the air temperature drops below  $59.7^\circ\text{C}$ . Since the canned drink is at a lower temperature than the dew-point temperature, some moisture will condense on the can, and thus it **will sweat**.

**14-32** The dry- and wet-bulb temperatures of atmospheric air at a specified pressure are given. The specific humidity, the relative humidity, and the enthalpy of air are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) We obtain the properties of water vapor from EES. The specific humidity  $\omega_1$  is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where  $T_2$  is the wet-bulb temperature, and  $\omega_2$  is determined from

$$\omega_2 = \frac{0.622 P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(1.938 \text{ kPa})}{(95 - 1.938) \text{ kPa}} = 0.01295 \text{ kg H}_2\text{O/kg dry air}$$

Thus,

$$\omega_1 = \frac{(1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(17 - 25)^\circ\text{C} + (0.01295)(2460.6 \text{ kJ/kg})}{(2546.5 - 71.36) \text{ kJ/kg}} = \mathbf{0.00963 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The relative humidity  $\phi_1$  is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.00963)(95 \text{ kPa})}{(0.622 + 0.00963)(3.1698 \text{ kPa})} = 0.457 \text{ or } \mathbf{45.7\%}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$h_1 = h_{a1} + \omega_1 h_{v1} \cong c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.00963)(2546.5 \text{ kJ/kg}) = \mathbf{49.65 \text{ kJ/kg dry air}}$$

**14-33** The dry- and wet-bulb temperatures of air in room at a specified pressure are given. The specific humidity, the relative humidity, and the dew-point temperature are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) We obtain the properties of water vapor from EES. The specific humidity  $\omega_1$  is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{f2}}{h_{g1} - h_{f2}}$$

where  $T_2$  is the wet-bulb temperature, and  $\omega_2$  is determined from

$$\omega_2 = \frac{0.622 P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(1.819 \text{ kPa})}{(100 - 1.819) \text{ kPa}} = 0.01152 \text{ kg H}_2\text{O/kg dry air}$$

100 kPa  
22°C  
 $T_{wb} = 16^\circ\text{C}$

Thus,

$$\omega_1 = \frac{(1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(16 - 22)^\circ\text{C} + (0.01152)(2463.0 \text{ kJ/kg})}{(2541.1 - 67.17) \text{ kJ/kg}} = \mathbf{0.00903 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The relative humidity  $\phi_1$  is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.00903)(100 \text{ kPa})}{(0.622 + 0.0091)(2.6452 \text{ kPa})} = 0.541 \text{ or } \mathbf{54.1\%}$$

(c) The vapor pressure at the inlet conditions is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat @ } 22^\circ\text{C}} = (0.541)(2.6452 \text{ kPa}) = 1.432 \text{ kPa}$$

Thus the dew-point temperature of the air is

$$T_{dp} = T_{\text{sat @ } P_v} = T_{\text{sat @ } 1.432 \text{ kPa}} = \mathbf{12.3^\circ\text{C}}$$

**14-34 EES** Problem 14-33 is reconsidered. The required properties are to be determined using EES at 100 and 300 kPa pressures.

**Analysis** The problem is solved using EES, and the solution is given below.

```
Tdb=22 [C]
Twb=16 [C]
P1=100 [kPa]
P2=300 [kPa]

h1=enthalpy(AirH2O;T=Tdb;P=P1;B=Twb)
v1=volume(AirH2O;T=Tdb;P=P1;B=Twb)
Tdp1=dewpoint(AirH2O;T=Tdb;P=P1;B=Twb)
w1=humrat(AirH2O;T=Tdb;P=P1;B=Twb)
Rh1=relhum(AirH2O;T=Tdb;P=P1;B=Twb)

h2=enthalpy(AirH2O;T=Tdb;P=P2;B=Twb)
v2=volume(AirH2O;T=Tdb;P=P2;B=Twb)
Tdp2=dewpoint(AirH2O;T=Tdb;P=P2;B=Twb)
w2=humrat(AirH2O;T=Tdb;P=P2;B=Twb)
Rh2=relhum(AirH2O;T=Tdb;P=P2;B=Twb)
```

#### SOLUTION

```
h1=45.09 [kJ/kg]
h2=25.54 [kJ/kg]
P1=100 [kPa]
P2=300 [kPa]
Rh1=0.541
Rh2=0.243
Tdb=22 [C]
Tdp1=12.3 [C]
Tdp2=0.6964 [C]
Twb=16 [C]
v1=0.8595 [m^3/kg]
v2=0.283 [m^3/kg]

w2=0.001336 [kgv/kg]
```

**14-35E** The dry- and wet-bulb temperatures of air in room at a specified pressure are given. The specific humidity, the relative humidity, and the dew-point temperature are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) The specific humidity  $\omega_1$  is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where  $T_2$  is the wet-bulb temperature, and  $\omega_2$  is determined from

$$\omega_2 = \frac{0.622 P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(0.30578 \text{ psia})}{(14.7 - 0.30578) \text{ psia}} = 0.01321 \text{ lbm H}_2\text{O/lbm dry air}$$

Thus,

$$\omega_1 = \frac{(0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(65 - 80)^\circ\text{F} + (0.01321)(1056.5 \text{ Btu/lbm})}{(1096.1 - 33.08) \text{ Btu/lbm}} = \mathbf{0.00974 \text{ lbm H}_2\text{O/lbm dry air}}$$

(b) The relative humidity  $\phi_1$  is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.00974)(14.7 \text{ psia})}{(0.622 + 0.00974)(0.50745 \text{ psia})} = 0.447 \text{ or } \mathbf{44.7\%}$$

(c) The vapor pressure at the inlet conditions is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat @ } 70^\circ\text{F}} = (0.447)(0.50745 \text{ psia}) = 0.2268 \text{ psia}$$

Thus the dew-point temperature of the air is

$$T_{\text{dp}} = T_{\text{sat @ } P_v} = T_{\text{sat @ } 0.2268 \text{ psia}} = \mathbf{56.6^\circ\text{F}} \quad (\text{from EES})$$

|                                                         |
|---------------------------------------------------------|
| 14.7 psia<br>80°F<br>$T_{\text{wb}} = 65^\circ\text{F}$ |
|---------------------------------------------------------|

**14-36** Atmospheric air flows steadily into an adiabatic saturation device and leaves as a saturated vapor. The relative humidity and specific humidity of air are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The exit state of the air is completely specified, and the total pressure is 98 kPa. The properties of the moist air at the exit state may be determined from EES to be

$$h_2 = 78.11 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.02079 \text{ kg H}_2\text{O/kg dry air}$$

The enthalpy of makeup water is

$$h_{w2} = h_{f@25^\circ\text{C}} = 104.83 \text{ kJ/kg} \quad (\text{Table A - 4})$$

An energy balance on the control volume gives

$$h_1 + (\omega_2 - \omega_1)h_w = h_2$$

$$h_1 + (0.02079 - \omega_1)(104.83 \text{ kJ/kg}) = 78.11 \text{ kJ/kg}$$

Pressure and temperature are known for inlet air. Other properties may be determined from this equation using EES. A hand solution would require a trial-error approach. The results are

$$h_1 = 77.66 \text{ kJ/kg dry air}$$

$$\omega_1 = \mathbf{0.01654 \text{ kg H}_2\text{O/kg dry air}}$$

$$\phi_1 = \mathbf{0.4511}$$

## Psychrometric Chart

**14-37C** They are very nearly parallel to each other.

**14-38C** The saturation states (located on the saturation curve).

**14-39C** By drawing a horizontal line until it intersects with the saturation curve. The corresponding temperature is the dew-point temperature.

**14-40C** No, they cannot. The enthalpy of moist air depends on  $\omega$ , which depends on the total pressure.

**14-41** [Also solved by EES on enclosed CD] The pressure, temperature, and relative humidity of air in a room are specified. Using the psychrometric chart, the specific humidity, the enthalpy, the wet-bulb temperature, the dew-point temperature, and the specific volume of the air are to be determined.

**Analysis** From the psychrometric chart (Fig. A-31) we read

(a)  $\omega = 0.0181 \text{ kg H}_2\text{O} / \text{kg dry air}$

(b)  $h = 78.4 \text{ kJ} / \text{kg dry air}$

(c)  $T_{wb} = 25.5^\circ\text{C}$

(d)  $T_{dp} = 23.3^\circ\text{C}$

(e)  $\nu = 0.890 \text{ m}^3 / \text{kg dry air}$

**14-42** The pressure, temperature, and relative humidity of air in a room are specified. Using the psychrometric chart, the specific humidity, the enthalpy, the wet-bulb temperature, the dew-point temperature, and the specific volume of the air are to be determined.

**Analysis** From the psychrometric chart (Fig. A-31) we read

(a)  $\omega = 0.0148 \text{ kg H}_2\text{O} / \text{kg dry air}$

(b)  $h = 63.9 \text{ kJ} / \text{kg dry air}$

(c)  $T_{wb} = 21.9^\circ\text{C}$

(d)  $T_{dp} = 20.1^\circ\text{C}$

(e)  $\nu = 0.868 \text{ m}^3 / \text{kg dry air}$

**14-43 EES** Problem 14-42 is reconsidered. The required properties are to be determined using EES. Also, the properties are to be obtained at an altitude of 2000 m.

**Analysis** The problem is solved using EES, and the solution is given below.

**14-46** The pressure, temperature, and relative humidity of air are specified. Using the psychrometric chart, the wet-bulb temperature, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

**Analysis** From the psychrometric chart in Fig. A-31 or using EES psychrometric functions we obtain

(a)  $T_{wb} = 27.1^\circ\text{C}$

(b)  $\omega = 0.0217 \text{ kg H}_2\text{O} / \text{kg dry air}$

(c)  $h = 85.5 \text{ kJ/kg dry air}$

(d)  $T_{dp} = 26.2^\circ\text{C}$

(e)  $P_v = \phi P_g = \phi P_{\text{sat}@30^\circ\text{C}} = (0.80)(4.2469 \text{ kPa}) = 3.40 \text{ kPa}$

|        |
|--------|
| Air    |
| 1 atm  |
| 30°C   |
| 80% RH |

**14-47E** The pressure, temperature, and wet-bulb temperature of air are specified. Using the psychrometric chart, the relative humidity, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

**Analysis** From the psychrometric chart in Fig. A-31 or using EES psychrometric functions we obtain

(a)  $\phi = 0.816 = 81.6\%$

(b)  $\omega = 0.0252 \text{ lbm H}_2\text{O} / \text{lbm dry air}$

(c)  $h = 49.4 \text{ Btu/lbm dry air}$

(d)  $T_{dp} = 83.7^\circ\text{F}$

(e)  $P_v = \phi P_g = \phi P_{\text{sat}@90^\circ\text{F}} = (0.816)(0.69904 \text{ psia}) = 0.570 \text{ psia}$

|                           |
|---------------------------|
| Air                       |
| 1 atm                     |
| 90°F                      |
| $T_{wb}=85^\circ\text{F}$ |

**14-48E** The pressure, temperature, and wet-bulb temperature of air are specified. The adiabatic saturation temperature is to be determined.

**Analysis** For an adiabatic saturation process, we obtained Eq. 14-14 in the text,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

This requires a trial-error solution for the adiabatic saturation temperature,  $T_2$ . The inlet state properties are

$$\omega_1 = 0.0252 \text{ lbm H}_2\text{O} / \text{lbm dry air}$$

$$h_{g1} = h_g @ 90^\circ\text{F} = 1100.4 \text{ Btu/lbm}$$

As a first estimate, let us take  $T_2 = 85^\circ\text{F}$  (the inlet wet-bulb temperature). Also, at the exit, the relative humidity is 100% ( $\phi_2 = 1$ ) and the pressure is 1 atm. Other properties at the exit state are

$$\omega_2 = 0.0264 \text{ lbm H}_2\text{O} / \text{lbm dry air}$$

$$h_{f2} = h_f @ 85^\circ\text{F} = 53.06 \text{ Btu/lbm (Table A - 4E)}$$

$$h_{fg2} = h_{fg} @ 85^\circ\text{F} = 1045.2 \text{ Btu/lbm (Table A - 4E)}$$

Substituting,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}} = \frac{(0.240)(85 - 90) + (0.0264)(1045.2)}{1100.4 - 53.06} = 0.0252 \text{ lbm H}_2\text{O} / \text{lbm dry air}$$

which is equal to the inlet specific humidity. Therefore, the adiabatic saturation temperature is

$$T_2 = \mathbf{85^\circ\text{F}}$$

**Discussion** This result is not surprising since the wet-bulb and adiabatic saturation temperatures are approximately equal to each other for air-water mixtures at atmospheric pressure.

**14-49** The pressure, temperature, and wet-bulb temperature of air are specified. Using the psychrometric chart, the relative humidity, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

**Analysis** From the psychrometric chart in Fig. A-31 or using EES psychrometric functions we obtain

$$(a) \phi = 0.618 = 61.8\%$$

$$(b) \omega = 0.0148 \text{ kg H}_2\text{O} / \text{kg dry air}$$

$$(c) h = 65.8 \text{ kJ/kg dry air}$$

$$(d) T_{wb} = 22.4^\circ\text{C}$$

$$(e) P_v = \phi P_g = \phi P_{\text{sat}} @ 28^\circ\text{C} = (0.618)(3.780 \text{ kPa}) = 2.34 \text{ kPa}$$

|                             |
|-----------------------------|
| Air                         |
| 1 atm                       |
| 28°C                        |
| $T_{dp} = 20^\circ\text{C}$ |

**14-50** The pressure, temperature, and wet-bulb temperature of air are specified. The adiabatic saturation temperature is to be determined.

**Analysis** For an adiabatic saturation process, we obtained Eq. 14-14 in the text,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

This requires a trial-error solution for the adiabatic saturation temperature,  $T_2$ . The inlet state properties are

$$\omega_1 = 0.0148 \text{ kg H}_2\text{O} / \text{kg dry air} \quad (\text{Fig. A-31})$$

$$h_{g1} = h_g @ 28^\circ\text{C} = 2551.9 \text{ kJ/kg} \quad (\text{Table A-4})$$

As a first estimate, let us take  $T_2 = 22^\circ\text{C}$  (the inlet wet-bulb temperature). Also, at the exit, the relative humidity is 100% ( $\phi_2 = 1$ ) and the pressure is 1 atm. Other properties at the exit state are

$$\omega_2 = 0.0167 \text{ kg H}_2\text{O} / \text{kg dry air}$$

$$h_{f2} = h_f @ 22^\circ\text{C} = 92.28 \text{ kJ/kg} \quad (\text{Table A-4})$$

$$h_{fg2} = h_{fg} @ 22^\circ\text{C} = 2448.8 \text{ kJ/kg} \quad (\text{Table A-4})$$

Substituting,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}} = \frac{(1.005)(22 - 28) + (0.0167)(2448.8)}{2551.9 - 92.28} = 0.0142 \text{ kg H}_2\text{O} / \text{kg dry air}$$

which is sufficiently close to the inlet specific humidity (0.0148). Therefore, the adiabatic saturation temperature is

$$T_2 \cong \mathbf{22^\circ\text{C}}$$

**Discussion** This result is not surprising since the wet-bulb and adiabatic saturation temperatures are approximately equal to each other for air-water mixtures at atmospheric pressure.

## Human Comfort and Air-Conditioning

**14-51C** It humidifies, dehumidifies, cleans and even deodorizes the air.

**14-52C** (a) Perspires more, (b) cuts the blood circulation near the skin, and (c) sweats excessively.

**14-53C** It is the direct heat exchange between the body and the surrounding surfaces. It can make a person feel chilly in winter, and hot in summer.

**14-54C** It affects by removing the warm, moist air that builds up around the body and replacing it with fresh air.

**14-55C** The spectators. Because they have a lower level of activity, and thus a lower level of heat generation within their bodies.

**14-56C** Because they have a large skin area to volume ratio. That is, they have a smaller volume to generate heat but a larger area to lose it from.

**14-57C** It affects a body's ability to perspire, and thus the amount of heat a body can dissipate through evaporation.

**14-58C** Humidification is to add moisture into an environment, dehumidification is to remove it.

**14-59C** The metabolism refers to the burning of foods such as carbohydrates, fat, and protein in order to perform the necessary bodily functions. The metabolic rate for an average man ranges from 108 W while reading, writing, typing, or listening to a lecture in a classroom in a seated position to 1250 W at age 20 (730 at age 70) during strenuous exercise. The corresponding rates for women are about 30 percent lower. Maximum metabolic rates of trained athletes can exceed 2000 W. We are interested in metabolic rate of the occupants of a building when we deal with heating and air conditioning because the metabolic rate represents the rate at which a body generates heat and dissipates it to the room. This body heat contributes to the heating in winter, but it adds to the cooling load of the building in summer.

**14-60C** The metabolic rate is proportional to the size of the body, and the metabolic rate of women, in general, is lower than that of men because of their smaller size. Clothing serves as insulation, and the thicker the clothing, the lower the environmental temperature that feels comfortable.

**14-61C** Sensible heat is the energy associated with a temperature change. The sensible heat loss from a human body increases as (a) the skin temperature increases, (b) the environment temperature decreases, and (c) the air motion (and thus the convection heat transfer coefficient) increases.

**14-62C** Latent heat is the energy released as water vapor condenses on cold surfaces, or the energy absorbed from a warm surface as liquid water evaporates. The latent heat loss from a human body increases as (a) the skin wetness increases and (b) the relative humidity of the environment decreases. The rate of evaporation from the body is related to the rate of latent heat loss by  $\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg}$  where  $h_{fg}$  is the latent heat of vaporization of water at the skin temperature.

**14-63** An average person produces 0.25 kg of moisture while taking a shower. The contribution of showers of a family of four to the latent heat load of the air-conditioner per day is to be determined.

**Assumptions** All the water vapor from the shower is condensed by the air-conditioning system.

**Properties** The latent heat of vaporization of water is given to be 2450 kJ/kg.

**Analysis** The amount of moisture produced per day is

$$\begin{aligned}\dot{m}_{\text{vapor}} &= (\text{Moisture produced per person})(\text{No. of persons}) \\ &= (0.25 \text{ kg / person})(4 \text{ persons / day}) = 1 \text{ kg / day}\end{aligned}$$

Then the latent heat load due to showers becomes

$$\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg} = (1 \text{ kg / day})(2450 \text{ kJ / kg}) = \mathbf{2450 \text{ kJ / day}}$$

**14-64** There are 100 chickens in a breeding room. The rate of total heat generation and the rate of moisture production in the room are to be determined.

**Assumptions** All the moisture from the chickens is condensed by the air-conditioning system.

**Properties** The latent heat of vaporization of water is given to be 2430 kJ/kg. The average metabolic rate of chicken during normal activity is 10.2 W (3.78 W sensible and 6.42 W latent).

**Analysis** The total rate of heat generation of the chickens in the breeding room is

$$\dot{Q}_{\text{gen, total}} = \dot{q}_{\text{gen, total}} (\text{No. of chickens}) = (10.2 \text{ W / chicken})(100 \text{ chickens}) = \mathbf{1020 \text{ W}}$$

The latent heat generated by the chicken and the rate of moisture production are

$$\begin{aligned}\dot{Q}_{\text{gen, latent}} &= \dot{q}_{\text{gen, latent}} (\text{No. of chickens}) \\ &= (6.42 \text{ W/chicken})(100 \text{ chickens}) = 642 \text{ W} \\ &= 0.642 \text{ kW}\end{aligned}$$

$$\dot{m}_{\text{moisture}} = \frac{\dot{Q}_{\text{gen, latent}}}{h_{fg}} = \frac{0.642 \text{ kJ / s}}{2430 \text{ kJ / kg}} = 0.000264 \text{ kg / s} = \mathbf{0.264 \text{ g / s}}$$

**14-65** A department store expects to have a specified number of people at peak times in summer. The contribution of people to the sensible, latent, and total cooling load of the store is to be determined.

**Assumptions** There is a mix of men, women, and children in the classroom.

**Properties** The average rate of heat generation from people doing light work is 115 W, and 70% of it is in sensible form (see Sec. 14-6).

**Analysis** The contribution of people to the sensible, latent, and total cooling load of the store are

$$\begin{aligned}\dot{Q}_{\text{people, total}} &= (\text{No. of people}) \times \dot{Q}_{\text{person, total}} = 135 \times (115 \text{ W}) = \mathbf{15,525 \text{ W}} \\ \dot{Q}_{\text{people, sensible}} &= (\text{No. of people}) \times \dot{Q}_{\text{person, sensible}} = 135 \times (0.7 \times 115 \text{ W}) = \mathbf{10,868 \text{ W}} \\ \dot{Q}_{\text{people, latent}} &= (\text{No. of people}) \times \dot{Q}_{\text{person, latent}} = 135 \times (0.3 \times 115 \text{ W}) = \mathbf{4658 \text{ W}}\end{aligned}$$

**14-66E** There are a specified number of people in a movie theater in winter. It is to be determined if the theater needs to be heated or cooled.

**Assumptions** There is a mix of men, women, and children in the classroom.

**Properties** The average rate of heat generation from people in a movie theater is 105 W, and 70 W of it is in sensible form and 35 W in latent form.

**Analysis** Noting that only the sensible heat from a person contributes to the heating load of a building, the contribution of people to the heating of the building is

$$\dot{Q}_{\text{people, sensible}} = (\text{No. of people}) \times \dot{Q}_{\text{person, sensible}} = 500 \times (70 \text{ W}) = 35,000 \text{ W} = \mathbf{119,420 \text{ Btu/h}}$$

since 1 W = 3.412 Btu/h. The building needs to be heated since the heat gain from people is less than the rate of heat loss of 130,000 Btu/h from the building.

**14-67** The infiltration rate of a building is estimated to be 1.2 ACH. The sensible, latent, and total infiltration heat loads of the building at sea level are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air infiltrates at the outdoor conditions, and exfiltrates at the indoor conditions. 3 Excess moisture condenses at room temperature of 24°C. 4 The effect of water vapor on air density is negligible.

**Properties** The gas constant and the specific heat of air are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  and  $c_p = 1.005 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-2). The heat of vaporization of water at 24°C is  $h_{fg} = h_{fg @ 24^\circ\text{C}} = 2444.1 \text{ kJ/kg}$  (Table A-4). The properties of the ambient and room air are determined from the psychrometric chart (Fig. A-31) to be

$$\left. \begin{array}{l} T_{\text{ambient}} = 32^\circ\text{C} \\ \phi_{\text{ambient}} = 50\% \end{array} \right\} w_{\text{ambient}} = 0.0150 \text{ kg/kg dry air}$$

$$\left. \begin{array}{l} T_{\text{room}} = 24^\circ\text{C} \\ \phi_{\text{room}} = 50\% \end{array} \right\} w_{\text{room}} = 0.0093 \text{ kg/kg dry air}$$

**Analysis** Noting that the infiltration of ambient air will cause the air in the cold storage room to be changed 1.2 times every hour, the air will enter the room at a mass flow rate of

$$\rho_{\text{ambient}} = \frac{P_0}{RT_0} = \frac{101.325 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(32 + 273 \text{ K})} = 1.158 \text{ kg/m}^3$$

$$\dot{m}_{\text{air}} = \rho_{\text{ambient}} \mathcal{V}_{\text{room}} \text{ACH} = (1.158 \text{ kg/m}^3)(20 \times 13 \times 3 \text{ m}^3)(1.2 \text{ h}^{-1}) = 1084 \text{ kg/h} = 0.301 \text{ kg/s}$$

Then the sensible, latent, and total infiltration heat loads of the room are determined to be

$$\dot{Q}_{\text{infiltration, sensible}} = \dot{m}_{\text{air}} c_p (T_{\text{ambient}} - T_{\text{room}}) = (0.301 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot^\circ\text{C})(32 - 24)^\circ\text{C} = \mathbf{2.42 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration, latent}} = \dot{m}_{\text{air}} (w_{\text{ambient}} - w_{\text{room}}) h_{fg} = (0.301 \text{ kg/s})(0.0150 - 0.0093)(2444.1 \text{ kJ/kg}) = \mathbf{4.16 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration, total}} = \dot{Q}_{\text{infiltration, sensible}} + \dot{Q}_{\text{infiltration, latent}} = 2.42 + 4.16 = \mathbf{6.58 \text{ kW}}$$

**Discussion** The specific volume of the dry air at the ambient conditions could also be determined from the psychrometric chart at ambient conditions.

**14-68** The infiltration rate of a building is estimated to be 1.8 ACH. The sensible, latent, and total infiltration heat loads of the building at sea level are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The air infiltrates at the outdoor conditions, and exfiltrates at the indoor conditions. 3 Excess moisture condenses at room temperature of 24°C. 4 The effect of water vapor on air density is negligible.

**Properties** The gas constant and the specific heat of air are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  and  $c_p = 1.005 \text{ kJ/kg}\cdot^\circ\text{C}$  (Table A-2). The heat of vaporization of water at 24°C is  $h_{fg} = h_{fg @ 24^\circ\text{C}} = 2444.1 \text{ kJ/kg}$  (Table A-4). The properties of the ambient and room air are determined from the psychrometric chart (Fig. A-31) to be

$$\left. \begin{array}{l} T_{\text{ambient}} = 32^\circ\text{C} \\ \phi_{\text{ambient}} = 50\% \end{array} \right\} w_{\text{ambient}} = 0.0150 \text{ kg/kg dry air}$$

$$\left. \begin{array}{l} T_{\text{room}} = 24^\circ\text{C} \\ \phi_{\text{room}} = 50\% \end{array} \right\} w_{\text{room}} = 0.0093 \text{ kg/kg dry air}$$

**Analysis** Noting that the infiltration of ambient air will cause the air in the cold storage room to be changed 1.8 times every hour, the air will enter the room at a mass flow rate of

$$\rho_{\text{ambient}} = \frac{P_0}{RT_0} = \frac{101.325 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(32 + 273 \text{ K})} = 1.158 \text{ kg/m}^3$$

$$\dot{m}_{\text{air}} = \rho_{\text{ambient}} \mathcal{V}_{\text{room}} \text{ACH} = (1.158 \text{ kg/m}^3)(20 \times 13 \times 3 \text{ m}^3)(1.8 \text{ h}^{-1}) = 1084 \text{ kg/h} = 0.4514 \text{ kg/s}$$

Then the sensible, latent, and total infiltration heat loads of the room are determined to be

$$\dot{Q}_{\text{infiltration, sensible}} = \dot{m}_{\text{air}} c_p (T_{\text{ambient}} - T_{\text{room}}) = (0.4514 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot^\circ\text{C})(32 - 24)^\circ\text{C} = \mathbf{3.63 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration, latent}} = \dot{m}_{\text{air}} (w_{\text{ambient}} - w_{\text{room}}) h_{fg} = (0.4514 \text{ kg/s})(0.0150 - 0.0093)(2444.1 \text{ kJ/kg}) = \mathbf{6.24 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration, total}} = \dot{Q}_{\text{infiltration, sensible}} + \dot{Q}_{\text{infiltration, latent}} = 3.63 + 6.24 = \mathbf{9.87 \text{ kW}}$$

**Discussion** The specific volume of the dry air at the ambient conditions could also be determined from the psychrometric chart at ambient conditions.

**Simple Heating and cooling**

**14-69C** Relative humidity decreases during a simple heating process and increases during a simple cooling process. Specific humidity, on the other hand, remains constant in both cases.

**14-70C** Because a horizontal line on the psychrometric chart represents a  $\omega = \text{constant}$  process, and the moisture content  $\omega$  of air remains constant during these processes.

**14-71** Air enters a cooling section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature, the exit relative humidity of the air, and the exit velocity are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The amount of moisture in the air remains constant ( $\omega_1 = \omega_2$ ) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 55.0 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0089 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$\nu_1 = 0.877 \text{ m}^3 / \text{kg dry air}$$

The mass flow rate of dry air through the cooling section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{\nu_1} V_1 A_1 \\ &= \frac{1}{(0.877 \text{ m}^3 / \text{kg})} (18 \text{ m/s})(\pi \times 0.4^2 / 4 \text{ m}^2) \\ &= 2.58 \text{ kg/s} \end{aligned}$$

From the energy balance on air in the cooling section,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= \dot{m}_a(h_2 - h_1) \\ -1200 / 60 \text{ kJ/s} &= (2.58 \text{ kg/s})(h_2 - 55.0) \text{ kJ/kg} \\ h_2 &= 47.2 \text{ kJ/kg dry air} \end{aligned}$$

The exit state of the air is fixed now since we know both  $h_2$  and  $\omega_2$ . From the psychrometric chart at this state we read

$$T_2 = 24.4^\circ\text{C}$$

$$(b) \quad \phi_2 = 46.6\%$$

$$\nu_2 = 0.856 \text{ m}^3 / \text{kg dry air}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\begin{aligned} \dot{m}_{a1} &= \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2} \\ V_2 &= \frac{\nu_2}{\nu_1} V_1 = \frac{0.856}{0.877} (18 \text{ m/s}) = 17.6 \text{ m/s} \end{aligned}$$

**14-72** Air enters a cooling section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature, the exit relative humidity of the air, and the exit velocity are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The amount of moisture in the air remains constant ( $\omega_1 = \omega_2$ ) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 55.0 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0089 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$\nu_1 = 0.877 \text{ m}^3 / \text{kg dry air}$$

The mass flow rate of dry air through the cooling section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{\nu_1} V_1 A_1 \\ &= \frac{1}{(0.877 \text{ m}^3 / \text{kg})} (18 \text{ m/s})(\pi \times 0.4^2 / 4 \text{ m}^2) \\ &= 2.58 \text{ kg/s} \end{aligned}$$

From the energy balance on air in the cooling section,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= \dot{m}_a(h_2 - h_1) \\ -800 / 60 \text{ kJ/s} &= (2.58 \text{ kg/s})(h_2 - 55.0) \text{ kJ/kg} \\ h_2 &= 49.8 \text{ kJ/kg dry air} \end{aligned}$$

The exit state of the air is fixed now since we know both  $h_2$  and  $\omega_2$ . From the psychrometric chart at this state we read

$$T_2 = 26.9^\circ\text{C}$$

$$(b) \quad \phi_2 = 40.0\%$$

$$\nu_2 = 0.862 \text{ m}^3 / \text{kg dry air}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\begin{aligned} \dot{m}_{a1} &= \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2} \\ V_2 &= \frac{\nu_2}{\nu_1} V_1 = \frac{0.862}{0.877} (18 \text{ m/s}) = 17.7 \text{ m/s} \end{aligned}$$

**14-73E** Humid air at a specified state is cooled at constant pressure to the dew-point temperature. The cooling required for this process is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The amount of moisture in the air remains constant ( $\omega_1 = \omega_2$ ) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 56.7 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0296 \text{ lbm H}_2\text{O/lbm dry air } (= \omega_2)$$

$$T_{dp,1} = 88.4^\circ\text{F}$$

The exit state enthalpy is

$$\left. \begin{array}{l} P = 1 \text{ atm} \\ T_2 = T_{dp,1} = 88.4^\circ\text{F} \\ \phi_1 = 1 \end{array} \right\} h_2 = 53.8 \text{ Btu/lbm dry air}$$

From the energy balance on air in the cooling section,

$$q_{\text{out}} = h_1 - h_2 = 56.7 - 53.8 = \mathbf{2.9 \text{ Btu/lbm dry air}}$$

**14-74** Humid air at a specified state is cooled at constant pressure to the dew-point temperature. The cooling required for this process is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The amount of moisture in the air remains constant ( $\omega_1 = \omega_2$ ) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 150 kPa. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@40^\circ\text{C}} = (0.70)(7.3851 \text{ kPa}) = 5.1696 \text{ kPa}$$

$$h_{g1} = h_g @ 40^\circ\text{C} = 2573.5 \text{ kJ/kg}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(5.1696 \text{ kPa})}{(150 - 5.1696) \text{ kPa}} = 0.02220 \text{ kg H}_2\text{O/kg dry air}$$

$$\begin{aligned} h_1 &= c_p T_1 + \omega_1 h_{g1} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(40^\circ\text{C}) + (0.02220)(2573.5 \text{ kJ/kg}) \\ &= 97.33 \text{ kJ/kg dry air} \end{aligned}$$

$$P_{v2} = P_{v1} = 5.1696 \text{ kPa}$$

$$P_{g2} = \frac{P_{v2}}{\phi_2} = \frac{5.1696 \text{ kPa}}{1} = 5.1696 \text{ kPa}$$

$$T_2 = T_{\text{sat}@5.1696 \text{ kPa}} = 33.5^\circ\text{C}$$

$$h_{g2} = h_g @ 33.5^\circ\text{C} = 2561.9 \text{ kJ/kg}$$

$$\omega_2 = \omega_1$$

$$\begin{aligned} h_2 &= c_p T_2 + \omega_2 h_{g2} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(33.5^\circ\text{C}) + (0.02220)(2561.9 \text{ kJ/kg}) \\ &= 90.55 \text{ kJ/kg dry air} \end{aligned}$$

From the energy balance on air in the cooling section,

$$q_{\text{out}} = h_1 - h_2 = 97.33 - 90.55 = \mathbf{6.78 \text{ kJ/kg dry air}}$$

**14-75** Saturated humid air at a specified state is heated to a specified temperature. The relative humidity at the exit and the rate of heat transfer are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The amount of moisture in the air remains constant ( $\omega_1 = \omega_2$ ) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 200 kPa. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@15^\circ\text{C}} = (1.0)(1.7057 \text{ kPa}) = 1.7057 \text{ kPa}$$

$$h_{g1} = h_{g@15^\circ\text{C}} = 2528.3 \text{ kJ/kg}$$

$$P_{a1} = P_1 - P_{v1} = 200 - 1.7057 = 198.29 \text{ kPa}$$

$$\begin{aligned} \nu_1 &= \frac{R_a T_1}{P_{a1}} \\ &= \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(288 \text{ K})}{198.29 \text{ kPa}} \\ &= 0.4168 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.7057 \text{ kPa})}{(200 - 1.7057) \text{ kPa}} = 0.005350 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(15^\circ\text{C}) + (0.005350)(2528.3 \text{ kJ/kg}) = 28.60 \text{ kJ/kg dry air}$$

$$P_{v2} = P_{v1} = 1.7057 \text{ kPa}$$

$$P_{g2} = P_{\text{sat}@30^\circ\text{C}} = 4.2469 \text{ kPa}$$

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{1.7057 \text{ kPa}}{4.2469 \text{ kPa}} = 0.402 = \mathbf{40.2\%}$$

$$h_{g2} = h_{g@30^\circ\text{C}} = 2555.6 \text{ kJ/kg}$$

$$\omega_2 = \omega_1$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.005350)(2555.6 \text{ kJ/kg}) = 43.82 \text{ kJ/kg dry air}$$

Then,

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (20 \text{ m/s}) \left( \frac{\pi (0.04 \text{ m})^2}{4} \right) = 0.02513 \text{ m}^3/\text{s}$$

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{0.02513 \text{ m}^3/\text{s}}{0.4168 \text{ m}^3/\text{kg dry air}} = 0.06029 \text{ kg/s}$$

From the energy balance on air in the heating section,

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (0.06029 \text{ kg/s})(43.82 - 28.60) \text{ kJ/kg} = \mathbf{0.918 \text{ kW}}$$

**14-76** Saturated humid air at a specified state is heated to a specified temperature. The rate at which the exergy of the humid air is increased is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The amount of moisture in the air remains constant ( $\omega_1 = \omega_2$ ) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 200 kPa. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@15^\circ\text{C}} = (1.0)(1.7057 \text{ kPa}) = 1.7057 \text{ kPa}$$

$$h_{g1} = h_g @ 15^\circ\text{C} = 2528.3 \text{ kJ/kg}$$

$$s_{g1} = s_g @ 15^\circ\text{C} = 8.7803 \text{ kJ/kg} \cdot \text{K}$$

$$P_{a1} = P_1 - P_{v1} = 200 - 1.7057 = 198.29 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(288 \text{ K})}{198.29 \text{ kPa}} = 0.4168 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.7057 \text{ kPa})}{(200 - 1.7057) \text{ kPa}} = 0.005350 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(15^\circ\text{C}) + (0.005350)(2528.3 \text{ kJ/kg}) = 28.60 \text{ kJ/kg dry air}$$

$$P_{v2} = P_{v1} = 1.7057 \text{ kPa}$$

$$P_{g2} = P_{\text{sat}@30^\circ\text{C}} = 4.2469 \text{ kPa}$$

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{1.7057 \text{ kPa}}{4.2469 \text{ kPa}} = 0.402 = \mathbf{40.2\%}$$

$$P_{a2} = P_2 - P_{v2} = 200 - 1.7057 = 198.29 \text{ kPa}$$

$$h_{g2} = h_g @ 30^\circ\text{C} = 2555.6 \text{ kJ/kg}$$

$$s_{g2} = s_g @ 30^\circ\text{C} = 8.4520 \text{ kJ/kg} \cdot \text{K}$$

$$\omega_2 = \omega_1$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.005350)(2555.6 \text{ kJ/kg}) = 43.82 \text{ kJ/kg dry air}$$

The entropy change of the dry air is

$$(s_2 - s_1)_{\text{dry air}} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} = (1.005) \ln \frac{303}{288} - (0.287) \ln \frac{198.29}{198.29} = 0.05103 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of the air-water mixture is

$$s_2 - s_1 = (s_2 - s_1)_{\text{dry air}} + \omega(s_2 - s_1)_{\text{water vapor}} = 0.05103 + (0.005350)(8.4520 - 8.7803) = 0.04927 \text{ kJ/kg} \cdot \text{K}$$

The mass flow rate of the dry air is

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (20 \text{ m/s}) \left( \frac{\pi (0.04 \text{ m})^2}{4} \right) = 0.02513 \text{ m}^3/\text{s}$$

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{0.02513 \text{ m}^3/\text{s}}{0.4168 \text{ m}^3/\text{kg dry air}} = 0.06029 \text{ kg/s}$$

The exergy increase of the humid air during this process is then,

$$\begin{aligned} \Delta\Phi &= \dot{m}_a (\psi_2 - \psi_1) = \dot{m}_a [(h_2 - h_1) - T_0 (s_2 - s_1)] \\ &= (0.06029 \text{ kg/s}) [(43.82 - 28.60) \text{ kJ/kg} - (288 \text{ K})(0.04927 \text{ kJ/kg} \cdot \text{K})] = \mathbf{0.062 \text{ kW/K}} \end{aligned}$$

## Heating with Humidification

**14-77C** To achieve a higher level of comfort. Very dry air can cause dry skin, respiratory difficulties, and increased static electricity.

**14-78** Air is first heated and then humidified by water vapor. The amount of steam added to the air and the amount of heat transfer to the air are to be determined.

**Assumptions** **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 31.1 \text{ kJ / kg dry air}$$

$$\omega_1 = 0.0064 \text{ kg H}_2\text{O / kg dry air} (= \omega_2)$$

$$h_2 = 36.2 \text{ kJ / kg dry air}$$

$$h_3 = 58.1 \text{ kJ / kg dry air}$$

$$\omega_3 = 0.0129 \text{ kg H}_2\text{O / kg dry air}$$

**Analysis** (a) The amount of moisture in the air remains constant it flows through the heating section ( $\omega_1 = \omega_2$ ), but increases in the humidifying section ( $\omega_3 > \omega_2$ ). The amount of steam added to the air in the heating section is

$$\Delta\omega = \omega_3 - \omega_2 = 0.0129 - 0.0064 = \mathbf{0.0065 \text{ kg H}_2\text{O / kg dry air}}$$

(b) The heat transfer to the air in the heating section per unit mass of air is

$$q_{\text{in}} = h_2 - h_1 = 36.2 - 31.1 = \mathbf{5.1 \text{ kJ / kg dry air}}$$

**14-79E** Air is first heated and then humidified by water vapor. The amount of steam added to the air and the amount of heat transfer to the air are to be determined.

**Assumptions** 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 17.0 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0046 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_2 = 22.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = \omega_1 = 0.0046 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_3 = 29.2 \text{ Btu/lbm dry air}$$

$$\omega_3 = 0.0102 \text{ lbm H}_2\text{O/lbm dry air}$$

**Analysis** (a) The amount of moisture in the air remains constant it flows through the heating section ( $\omega_1 = \omega_2$ ), but increases in the humidifying section ( $\omega_3 > \omega_2$ ). The amount of steam added to the air in the heating section is

$$\Delta\omega = \omega_3 - \omega_2 = 0.0102 - 0.0046 = \mathbf{0.0056 \text{ lbm H}_2\text{O/lbm dry air}}$$

(b) The heat transfer to the air in the heating section per unit mass of air is

$$q_{\text{in}} = h_2 - h_1 = 22.3 - 17.0 = \mathbf{5.3 \text{ Btu/lbm dry air}}$$

**14-80** Air is first heated and then humidified by wet steam. The temperature and relative humidity of air at the exit of heating section, the rate of heat transfer, and the rate at which water is added to the air are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 23.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0053 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$\nu_1 = 0.809 \text{ m}^3/\text{kg dry air}$$

$$h_3 = 42.3 \text{ kJ/kg dry air}$$

$$\omega_3 = 0.0087 \text{ kg H}_2\text{O/kg dry air}$$

**Analysis (a)** The amount of moisture in the air remains constant as it flows through the heating section ( $\omega_1 = \omega_2$ ), but increases in the humidifying section ( $\omega_3 > \omega_2$ ). The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{35 \text{ m}^3/\text{min}}{0.809 \text{ m}^3/\text{kg}} = 43.3 \text{ kg/min}$$

Noting that  $Q = W = 0$ , the energy balance on the humidifying section can be expressed as

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{no (steady)}} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_w h_w + \dot{m}_{a2} h_2 = \dot{m}_a h_3 \\ (\omega_3 - \omega_2) h_w + h_2 &= h_3 \end{aligned}$$

Solving for  $h_2$ ,

$$h_2 = h_3 - (\omega_3 - \omega_2) h_{g@100^\circ\text{C}} = 42.3 - (0.0087 - 0.0053)(2675.6) = 33.2 \text{ kJ/kg dry air}$$

Thus at the exit of the heating section we have  $\omega_2 = 0.0053 \text{ kg H}_2\text{O dry air}$  and  $h_2 = 33.2 \text{ kJ/kg dry air}$ , which completely fixes the state. Then from the psychrometric chart we read

$$T_2 = 19.5^\circ\text{C}$$

$$\phi_2 = 37.8\%$$

(b) The rate of heat transfer to the air in the heating section is

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (43.3 \text{ kg/min})(33.2 - 23.5) \text{ kJ/kg} = \mathbf{420 \text{ kJ/min}}$$

(c) The amount of water added to the air in the humidifying section is determined from the conservation of mass equation of water in the humidifying section,

$$\dot{m}_w = \dot{m}_a (\omega_3 - \omega_2) = (43.3 \text{ kg/min})(0.0087 - 0.0053) = \mathbf{0.15 \text{ kg/min}}$$

**14-81** Air is first heated and then humidified by wet steam. The temperature and relative humidity of air at the exit of heating section, the rate of heat transfer, and the rate at which water is added to the air are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The amount of moisture in the air also remains constant it flows through the heating section ( $\omega_1 = \omega_2$ ), but increases in the humidifying section ( $\omega_3 > \omega_2$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. The properties of the air at various states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@10^\circ\text{C}} = (0.70)(1.2281 \text{ kPa}) = 0.860 \text{ kPa} (= P_{v2})$$

$$P_{a1} = P_1 - P_{v1} = 95 - 0.860 = 94.14 \text{ kPa}$$

$$v_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(283 \text{ K})}{94.14 \text{ kPa}} = 0.863 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.86 \text{ kPa})}{(95 - 0.86) \text{ kPa}} = 0.00568 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(10^\circ\text{C}) + (0.00568)(2519.2 \text{ kJ/kg}) = 24.36 \text{ kJ/kg dry air}$$

$$P_{v3} = \phi_3 P_{g3} = \phi_3 P_{\text{sat}@20^\circ\text{C}} = (0.60)(2.3392 \text{ kPa}) = 1.40 \text{ kPa}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}} = \frac{0.622(1.40 \text{ kPa})}{(95 - 1.40) \text{ kPa}} = 0.00930 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = c_p T_3 + \omega_3 h_{g3} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0093)(2537.4 \text{ kJ/kg}) = 43.70 \text{ kJ/kg dry air}$$

Also,

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{35 \text{ m}^3 / \text{min}}{0.863 \text{ m}^3 / \text{kg}} = 40.6 \text{ kg/min}$$

Noting that  $Q = W = 0$ , the energy balance on the humidifying section gives

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{=} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i \longrightarrow \dot{m}_w h_w + \dot{m}_a h_2 = \dot{m}_a h_3 \longrightarrow (\omega_3 - \omega_2) h_w + h_2 = h_3$$

$$h_2 = h_3 - (\omega_3 - \omega_2) h_{g@100^\circ\text{C}} = 43.7 - (0.0093 - 0.00568) \times 2675.6 = 34.0 \text{ kJ/kg dry air}$$

Thus at the exit of the heating section we have  $\omega = 0.00568 \text{ kg H}_2\text{O dry air}$  and  $h_2 = 34.0 \text{ kJ/kg dry air}$ , which completely fixes the state. The temperature of air at the exit of the heating section is determined from the definition of enthalpy,

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82 T_2)$$

$$34.0 = (1.005) T_2 + (0.00568)(2500.9 + 1.82 T_2)$$

Solving for  $h_2$ , yields

$$T_2 = \mathbf{19.5^\circ \text{C}}$$

The relative humidity at this state is

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{P_{v2}}{P_{\text{sat}@19.5^\circ\text{C}}} = \frac{0.859 \text{ kPa}}{2.2759 \text{ kPa}} = 0.377 \quad \text{or} \quad \mathbf{37.7\%}$$

(b) The rate of heat transfer to the air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (40.6 \text{ kg/min})(34.0 - 24.36) \text{ kJ/kg} = \mathbf{391 \text{ kJ/min}}$$

(c) The amount of water added to the air in the humidifying section is determined from the conservation of mass equation of water in the humidifying section,

$$\dot{m}_w = \dot{m}_a (\omega_3 - \omega_2) = (40.6 \text{ kg/min})(0.0093 - 0.00568) = \mathbf{0.147 \text{ kg/min}}$$

## Cooling with Dehumidification

**14-82C** To drop its relative humidity to more desirable levels.

**14-83** Air is first cooled, then dehumidified, and finally heated. The temperature of air before it enters the heating section, the amount of heat removed in the cooling section, and the amount of heat supplied in the heating section are to be determined.

**Assumptions** **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** (a) The amount of moisture in the air decreases due to dehumidification ( $\omega_3 < \omega_1$ ), and remains constant during heating ( $\omega_3 = \omega_2$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The intermediate state (state 2) is also known since  $\phi_2 = 100\%$  and  $\omega_2 = \omega_3$ . Therefore, we can determine the properties of the air at all three states from the psychrometric chart (Fig. A-31) to be

$$\begin{aligned} h_1 &= 95.2 \text{ kJ / kg dry air} \\ \omega_1 &= 0.0238 \text{ kg H}_2\text{O / kg dry air} \\ \text{and} \\ h_3 &= 43.1 \text{ kJ / kg dry air} \\ \omega_3 &= 0.0082 \text{ kg H}_2\text{O / kg dry air} (= \omega_2) \end{aligned}$$

Also,

$$\begin{aligned} h_w &\cong h_f @ 10^\circ\text{C} = 42.02 \text{ kJ/kg (Table A - 4)} \\ h_2 &= 31.8 \text{ kJ/kg dry air} \\ T_2 &= 11.1^\circ\text{C} \end{aligned}$$

(b) The amount of heat removed in the cooling section is determined from the energy balance equation applied to the cooling section,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e + \dot{Q}_{\text{out,cooling}} \\ \dot{Q}_{\text{out,cooling}} &= \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w \end{aligned}$$

or, per unit mass of dry air,

$$\begin{aligned} q_{\text{out,cooling}} &= (h_1 - h_2) - (\omega_1 - \omega_2) h_w \\ &= (95.2 - 31.8) - (0.0238 - 0.0082) 42.02 \\ &= 62.7 \text{ kJ/kg dry air} \end{aligned}$$

(c) The amount of heat supplied in the heating section per unit mass of dry air is

$$q_{\text{in,heating}} = h_3 - h_2 = 43.1 - 31.8 = 11.3 \text{ kJ / kg dry air}$$

**14-84 [Also solved by EES on enclosed CD]** Air is cooled by passing it over a cooling coil through which chilled water flows. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

**Assumptions** 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

**Analysis** (a) The saturation pressure of water at 35°C is 5.6291 kPa (Table A-4). Then the dew point temperature of the incoming air stream at 35°C becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.6 \times 5.6291 \text{ kPa}} = 26^\circ\text{C} \quad (\text{Table A-5})$$

since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense. The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 90.3 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0215 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.904 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 57.5 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_2 = 0.851 \text{ m}^3/\text{kg dry air}$$

Also,  $h_w \cong h_f @ 20^\circ\text{C} = 83.93 \text{ kJ/kg}$  (Table A-4)

Then,

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (120 \text{ m/min}) \left( \frac{\pi (0.3 \text{ m})^2}{4} \right) = 8.48 \text{ m}^3 / \text{min}$$

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{8.48 \text{ m}^3 / \text{min}}{0.904 \text{ m}^3 / \text{kg dry air}} = 9.38 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the water),

**Water Mass Balance:**  $\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (9.38 \text{ kg/min})(0.0215 - 0.0147) = 0.064 \text{ kg/min}$$

**Energy Balance:**

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \overset{\text{no (steady)}}{=} 0 \longrightarrow \dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{out} \longrightarrow \dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (9.38 \text{ kg/min})(90.3 - 57.5) \text{ kJ/kg} - (0.064 \text{ kg/min})(83.93 \text{ kJ/kg}) = \mathbf{302.3 \text{ kJ/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{cooling \text{ water}} = \dot{m}_{cooling \text{ water}} \Delta h = \dot{m}_{cooling \text{ water}} c_p \Delta T$$

$$\dot{m}_{cooling \text{ water}} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{302.3 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(8^\circ\text{C})} = \mathbf{9.04 \text{ kg/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2}$$

$$V_2 = \frac{\nu_2}{\nu_1} V_1 = \frac{0.851}{0.904} (120 \text{ m/min}) = \mathbf{113 \text{ m/min}}$$

**14-85 EES** Problem 14-84 is reconsidered. A general solution of the problem in which the input variables may be supplied and parametric studies performed is to be developed and the process is to be shown in the psychrometric chart for each set of input variables.

**Analysis** The problem is solved using EES, and the solution is given below.

**14-86** Air is cooled by passing it over a cooling coil. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The dew point temperature of the incoming air stream at 35°C is

$$\begin{aligned} P_{v1} &= \phi_1 P_{g1} = \phi_1 P_{\text{sat}@35^\circ\text{C}} \\ &= (0.6)(5.6291 \text{ kPa}) = 3.38 \text{ kPa} \\ T_{\text{dp}} &= T_{\text{sat}@P_v} = T_{\text{sat}@3.38 \text{ kPa}} = 25.9^\circ\text{C} \end{aligned}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. Then the properties of the air at both states are determined to be

$$\begin{aligned} P_{a1} &= P_1 - P_{v1} = 95 - 3.38 = 91.62 \text{ kPa} \\ \nu_1 &= \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(308 \text{ K})}{91.62 \text{ kPa}} = 0.965 \text{ m}^3 / \text{kg dry air} \\ \omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(3.38 \text{ kPa})}{(95 - 3.38) \text{ kPa}} = 0.0229 \text{ kg H}_2\text{O/kg dry air} \\ h_1 &= c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.0229)(2564.6 \text{ kJ/kg}) \\ &= 93.90 \text{ kJ/kg dry air} \end{aligned}$$

and

$$\begin{aligned} P_{v2} &= \phi_2 P_{g2} = (1.00)P_{\text{sat}@20^\circ\text{C}} = 2.3392 \text{ kPa} \\ \nu_2 &= \frac{R_a T_2}{P_{a2}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{(95 - 2.339) \text{ kPa}} = 0.908 \text{ m}^3 / \text{kg dry air} \\ \omega_2 &= \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(2.339 \text{ kPa})}{(95 - 2.339) \text{ kPa}} = 0.0157 \text{ kg H}_2\text{O/kg dry air} \\ h_2 &= c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0157)(2537.4 \text{ kJ/kg}) \\ &= 59.95 \text{ kJ/kg dry air} \end{aligned}$$

Also,

$$h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg} \quad (\text{Table A-4})$$

Then,

$$\begin{aligned} \dot{V}_1 &= V_1 A_1 = V_1 \frac{\pi D^2}{4} = (120 \text{ m/min}) \left( \frac{\pi (0.3 \text{ m})^2}{4} \right) = 8.48 \text{ m}^3 / \text{min} \\ \dot{m}_{a1} &= \frac{\dot{V}_1}{\nu_1} = \frac{8.48 \text{ m}^3 / \text{min}}{0.965 \text{ m}^3 / \text{kg dry air}} = 8.79 \text{ kg/min} \end{aligned}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section (excluding the water),

*Water Mass Balance:*

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (8.79 \text{ kg/min})(0.0229 - 0.0157) = 0.0633 \text{ kg/min}$$

*Energy Balance:*

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{\text{out}} \rightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (8.79 \text{ kg/min})(93.90 - 59.94) \text{ kJ/kg} - (0.0633 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{293.2 \text{ kJ/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{\text{cooling water}} = \dot{m}_{\text{cooling water}} \Delta h = \dot{m}_{\text{cooling water}} c_p \Delta T$$

$$\dot{m}_{\text{cooling water}} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{293.2 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(8^\circ\text{C})} = \mathbf{8.77 \text{ kg/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2}$$

$$V_2 = \frac{\nu_2}{\nu_1} V_1 = \frac{0.908}{0.965} (120 \text{ m/min}) = \mathbf{113 \text{ m/min}}$$

**14-87** Air is cooled and dehumidified at constant pressure. The amount of water removed from the air and the cooling requirement are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 85.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0217 \text{ kg H}_2\text{O/kg dry air}$$

and

$$\phi_2 = 1.0$$

$$h_2 = 57.6 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0148 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 22^\circ\text{C} = 92.28 \text{ kJ/kg} \quad (\text{Table A-4})$$

**Analysis** The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\Delta\omega = \omega_1 - \omega_2 = 0.0217 - 0.0148 = \mathbf{0.0069 \text{ kg H}_2\text{O/kg dry air}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta\dot{E}_{\text{system}} \quad \phi^0(\text{steady}) = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$q_{\text{out}} = h_1 - h_2 - (\omega_1 - \omega_2)h_w$$

$$= (85.5 - 57.6) \text{ kJ/kg} - (0.0069)(92.28)$$

$$= \mathbf{27.3 \text{ kJ/kg dry air}}$$

**14-88E** Air is cooled and dehumidified at constant pressure. The amount of water removed from the air and the rate of cooling are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 37.8 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0158 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 14.08 \text{ ft}^3/\text{lbm dry air}$$

and

$$\phi_2 = 1.0$$

$$h_2 = 26.5 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0111 \text{ lbm H}_2\text{O/lbm dry air}$$

Also,

$$h_w \cong h_f @ 65^\circ\text{F} = 33.08 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

**Analysis** The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The mass flow rate of air is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{(10,000 / 3600) \text{ ft}^3 / \text{s}}{14.08 \text{ ft}^3 / \text{lbm dry air}} = 0.1973 \text{ lbm/s}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (0.1973 \text{ lbm/s})(0.0158 - 0.0111) = \mathbf{0.000927 \text{ lbm/s}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \quad \phi^0(\text{steady}) = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (0.1973 \text{ lbm/s})(37.8 - 26.5) \text{ Btu/lbm} - (0.000927 \text{ lbm/s})(33.08 \text{ Btu/lbm})$$

$$= \mathbf{2.20 \text{ Btu/s}}$$

**14-89** Air is cooled and dehumidified at constant pressure. The amount of water removed from the air and the rate of cooling are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 106.8 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0292 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.905 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 52.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0112 \text{ kg H}_2\text{O/kg dry air}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit. Then,

$$h_w \cong h_f @ 28^\circ\text{C} = 117.4 \text{ kJ/kg} \quad (\text{Table A-4})$$

**Analysis** The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The mass of air is

$$m_a = \frac{\nu_1}{\nu_1} = \frac{1000 \text{ m}^3}{0.905 \text{ m}^3 / \text{kg dry air}} = 1105 \text{ kg}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$m_w = m_a (\omega_1 - \omega_2) = (1105 \text{ kg})(0.0292 - 0.0112) = \mathbf{19.89 \text{ kg}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\text{steady}}{\neq 0} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$Q_{\text{out}} = m_a (h_1 - h_2) - m_w h_w$$

$$Q_{\text{out}} = (1105 \text{ kg})(106.8 - 52.7) \text{ kJ/kg} - (19.89 \text{ kg})(117.4 \text{ kJ/kg})$$

$$= \mathbf{57,450 \text{ kJ}}$$

**14-90** The humid air of the previous problem is reconsidered. The exit temperature of the air to produce the desired dehumidification is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be (from the data of the previous problem)

$$h_1 = 106.8 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0292 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.905 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 52.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0112 \text{ kg H}_2\text{O/kg dry air}$$

**Analysis** For the desired dehumidification, the air at the exit should be saturated with a specific humidity of 0.0112 kg water/kg dry air. That is,

$$\phi_2 = 1.0$$

$$\omega_2 = 0.0112 \text{ kg H}_2\text{O/kg dry air}$$

The temperature of the air at this state is

$$T_2 = \mathbf{15.8^\circ\text{C}}$$

**14-91** Air is cooled and dehumidified at constant pressure. The cooling required is provided by a simple ideal vapor-compression refrigeration system using refrigerant-134a as the working fluid. The exergy destruction in the total system per 1000 m<sup>3</sup> of dry air is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 106.8 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0292 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.905 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 52.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0112 \text{ kg H}_2\text{O/kg dry air}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit. Then, from Table A-4,

$$h_w \cong h_f @ 28^\circ\text{C} = 117.4 \text{ kJ/kg}$$

**Analysis** The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The mass of air is

$$m_a = \frac{\nu_1}{\nu_1} = \frac{1000 \text{ m}^3}{0.905 \text{ m}^3/\text{kg dry air}} = 1105 \text{ kg}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$m_w = m_a(\omega_1 - \omega_2) = (1105 \text{ kg})(0.0292 - 0.0112) = 19.89 \text{ kg}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$Q_{\text{out}} = m_a(h_1 - h_2) - m_w h_w$$

$$Q_{\text{out}} = (1105 \text{ kg})(106.8 - 52.7) \text{ kJ/kg} - (19.89 \text{ kg})(117.4 \text{ kJ/kg}) = 57,450 \text{ kJ}$$

We obtain the properties for the vapor-compression refrigeration cycle as follows (Tables A-11, through A-13):

$$\left. \begin{array}{l} T_1 = 4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 4^\circ\text{C} = 252.77 \text{ kJ/kg} \\ s_1 = s_g @ 4^\circ\text{C} = 0.92927 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = P_{\text{sat}} @ 39.4^\circ\text{C} = 1 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 275.29 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 1 \text{ MPa} = 107.32 \text{ kJ/kg} \\ s_3 = s_f @ 1 \text{ MPa} = 0.39189 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$h_4 \cong h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_4 = 4^\circ\text{C} \\ h_4 = 107.32 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} x_4 = 0.2561 \\ s_4 = 0.4045 \text{ kJ/kg} \cdot \text{K} \end{array}$$

The mass flow rate of refrigerant-134a is

$$m_R = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{57,450 \text{ kJ}}{(252.77 - 107.32) \text{ kJ/kg}} = 395.0 \text{ kg}$$

The amount of heat rejected from the condenser is

$$\dot{Q}_H = m_R (h_2 - h_3) = (395.0 \text{ kg})(275.29 - 107.32) \text{ kJ/kg} = 66,350 \text{ kJ}$$

Next, we calculate the exergy destruction in the components of the refrigeration cycle:

$$X_{\text{destroyed},12} = m_R T_0 (s_2 - s_1) = 0 \quad (\text{since the process is isentropic})$$

$$\begin{aligned} X_{\text{destroyed},23} &= T_0 \left( m_R (s_3 - s_2) + \frac{\dot{Q}_H}{T_H} \right) \\ &= (305 \text{ K}) \left( (395 \text{ kg})(0.39189 - 0.92927) \text{ kJ/kg} \cdot \text{K} + \frac{66,350 \text{ kJ}}{305 \text{ K}} \right) = 1609 \text{ kJ} \end{aligned}$$

$$X_{\text{destroyed},34} = m_R T_0 (s_4 - s_3) = (395 \text{ kg})(305 \text{ K})(0.4045 - 0.39189) \text{ kJ/kg} \cdot \text{K} = 1519 \text{ kJ}$$

The entropies of water vapor in the air stream are

$$s_{g1} = s_g @ 32^\circ\text{C} = 8.4114 \text{ kJ/kg} \cdot \text{K}$$

$$s_{g2} = s_g @ 24^\circ\text{C} = 8.5782 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of water vapor in the air stream is

$$\Delta S_{\text{vapor}} = m_a (\omega_2 s_{g2} - \omega_1 s_{g1}) = (1105)(0.0112 \times 8.5782 - 0.0292 \times 8.4114) = -165.2 \text{ kJ/K}$$

The entropy of water leaving the cooling section is

$$S_w = m_w s_f @ 28^\circ\text{C} = (19.89 \text{ kg})(0.4091 \text{ kJ/kg} \cdot \text{K}) = 8.14 \text{ kJ/K}$$

The partial pressures of water vapor and dry air for air streams are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 32^\circ\text{C} = (0.95)(4.760 \text{ kPa}) = 4.522 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 101.325 - 4.522 = 96.80 \text{ kPa}$$

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}} @ 24^\circ\text{C} = (0.60)(2.986 \text{ kPa}) = 1.792 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 101.325 - 1.792 = 99.53 \text{ kPa}$$

The entropy change of dry air is

$$\begin{aligned}\Delta S_a &= m_a (s_2 - s_1) = m_a \left( c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} \right) \\ &= (1105) \left[ (1.005) \ln \frac{297}{305} - (0.287) \ln \frac{99.53}{96.80} \right] = -38.34 \text{ kJ/kg dry air}\end{aligned}$$

The entropy change of R-134a in the evaporator is

$$\Delta S_{R, 41} = m_R (s_1 - s_4) = (395 \text{ kg})(0.92927 - 0.4045) = 207.3 \text{ kJ/K}$$

An entropy balance on the evaporator gives

$$S_{\text{gen, evaporator}} = \Delta S_{R,41} + \Delta S_{\text{vapor}} + \Delta S_a + S_w = 207.3 + (-165.2) + (-38.34) + 8.14 = 11.90 \text{ kJ/K}$$

Then, the exergy destruction in the evaporator is

$$X_{\text{dest}} = T_0 S_{\text{gen, evaporator}} = (305 \text{ K})(11.90 \text{ kJ/K}) = 3630 \text{ kJ}$$

Finally the total exergy destruction is

$$\begin{aligned}X_{\text{dest, total}} &= X_{\text{dest, compressor}} + X_{\text{dest, condenser}} + X_{\text{dest, throttle}} + X_{\text{dest, evaporator}} \\ &= 0 + 1609 + 1519 + 3630 \\ &= \mathbf{6758 \text{ kJ}}\end{aligned}$$

The greatest exergy destruction occurs in the evaporator. Note that heat is absorbed from humid air and rejected to the ambient air at 32°C (305 K), which is also taken as the dead state temperature.

**14-92** Atmospheric air enters the evaporator of an automobile air conditioner at a specified pressure, temperature, and relative humidity. The dew point and wet bulb temperatures at the inlet to the evaporator section, the required heat transfer rate from the atmospheric air to the evaporator fluid, and the rate of condensation of water vapor in the evaporator section are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$T_{dp1} = 15.7^\circ\text{C}$$

$$T_{wb1} = 19.5^\circ\text{C}$$

$$h_1 = 55.60 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01115 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8655 \text{ m}^3 / \text{kg dry air}$$

$$h_2 = 27.35 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00686 \text{ kg H}_2\text{O/kg dry air}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{\nu_{car} \text{ACH}}{\nu_1} = \frac{(2 \text{ m}^3/\text{change})(5 \text{ changes/min})}{0.8655 \text{ m}^3} = 11.55 \text{ kg/min}$$

The mass flow rates of vapor at the inlet and exit are

$$\dot{m}_{v1} = \omega_1 \dot{m}_a = (0.01115)(11.55 \text{ kg/min}) = 0.1288 \text{ kg/min}$$

$$\dot{m}_{v2} = \omega_2 \dot{m}_a = (0.00686)(11.55 \text{ kg/min}) = 0.07926 \text{ kg/min}$$

An energy balance on the control volume gives

$$\dot{m}_a h_1 = \dot{Q}_{out} + \dot{m}_a h_2 + \dot{m}_w h_{w2}$$

where the the enthalpy of condensate water is

$$h_{w2} = h_{f@10^\circ\text{C}} = 42.02 \text{ kJ/kg} \quad (\text{Table A - 4})$$

and the rate of condensation of water vapor is

$$\dot{m}_w = \dot{m}_{v1} - \dot{m}_{v2} = 0.1288 - 0.07926 = 0.0495 \text{ kg/min}$$

Substituting,

$$\begin{aligned} \dot{m}_a h_1 &= \dot{Q}_{out} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (11.55 \text{ kg/min})(55.60 \text{ kJ/kg}) &= \dot{Q}_{out} + (11.55 \text{ kg/min})(27.35 \text{ kJ/kg}) + (0.0495 \text{ kg/min})(42.02 \text{ kJ/kg}) \\ \dot{Q}_{out} &= 324.4 \text{ kJ/min} = \mathbf{5.41 \text{ kW}} \end{aligned}$$

**14-93** Atmospheric air flows into an air conditioner that uses chilled water as the cooling fluid. The mass flow rate of the condensate water and the volume flow rate of chilled water supplied to the air conditioner are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** We may assume that the exit relative humidity is 100 percent since the exit temperature (18°C) is below the dew-point temperature of the inlet air (25°C). The properties of the air at the exit state may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$h_2 = 51.34 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.01311 \text{ kg H}_2\text{O/kg dry air}$$

The partial pressure of water vapor at the inlet state is (Table A-4)

$$P_{v1} = P_{\text{sat}@ 25^\circ\text{C}} = 3.17 \text{ kPa}$$

The saturation pressure at the inlet state is

$$P_{g1} = P_{\text{sat}@ 28^\circ\text{C}} = 3.783 \text{ kPa (Table A - 4)}$$

Then, the relative humidity at the inlet state becomes

$$\phi_1 = \frac{P_{v1}}{P_{g1}} = \frac{3.17}{3.783} = 0.8379$$

Now, the inlet state is also fixed. The properties are obtained from EES to be

$$h_1 = 80.14 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.02036 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8927 \text{ m}^3/\text{kg}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{(2000 / 60) \text{ m}^3/\text{h}}{0.8927 \text{ m}^3/\text{kg}} = 37.34 \text{ kg/min}$$

The mass flow rate of condensate water is

$$\begin{aligned} \dot{m}_w &= \dot{m}_a (\omega_1 - \omega_2) \\ &= (37.34 \text{ kg/min})(0.02036 - 0.01311) \\ &= 0.2707 \text{ kg/min} \\ &= \mathbf{16.24 \text{ kg/h}} \end{aligned}$$

The enthalpy of condensate water is

$$h_{w2} = h_{f@ 18^\circ\text{C}} = 75.54 \text{ kJ/kg (Table A - 4)}$$

An energy balance on the control volume gives

$$\begin{aligned}\dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (37.34 \text{ kg/min})(80.14 \text{ kJ/kg}) &= \dot{Q}_{\text{out}} + (37.34 \text{ kg/min})(51.34 \text{ kJ/kg}) + (0.2707 \text{ kg/min})(75.54 \text{ kJ/kg}) \\ \dot{Q}_{\text{out}} &= 1055 \text{ kJ/min} = 17.59 \text{ kW}\end{aligned}$$

Noting that the rate of heat lost from the air is received by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{\text{in}} = \dot{m}_{cw} c_p \Delta T_{cw} \longrightarrow \dot{m}_{cw} = \frac{\dot{Q}_{\text{in}}}{c_p \Delta T_{cw}} = \frac{1055 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(10^\circ\text{C})} = 25.24 \text{ kg/min}$$

where we used the specific heat of water value at room temperature. Assuming a density of  $1000 \text{ kg/m}^3$  for water, the volume flow rate is determined to be

$$\dot{V}_{cw} = \frac{\dot{m}_{cw}}{\rho_{cw}} = \frac{25.24 \text{ kg/min}}{1000 \text{ kg/m}^3} = 0.0252 \text{ m}^3/\text{min}$$

**14-94** An automobile air conditioner using refrigerant 134a as the cooling fluid is considered. The inlet and exit states of moist air in the evaporator are specified. The volume flow rate of the air entering the evaporator of the air conditioner is to be determined.

**Assumptions** 1 All processes are steady flow and the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

**Analysis** We assume that the total pressure of moist air is 100 kPa. Then, the inlet and exit states of the moist air for the evaporator are completely specified. The properties may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$\begin{aligned} h_1 &= 43.33 \text{ kJ/kg dry air} \\ \omega_1 &= 0.008337 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 &= 0.8585 \text{ m}^3/\text{kg dry air} \\ h_2 &= 23.31 \text{ kJ/kg dry air} \\ \omega_2 &= 0.006065 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

The mass flow rate of dry air is given by

$$\dot{m}_a = \frac{\dot{\nu}_1}{\nu_1} = \frac{\dot{\nu}_1}{0.8585 \text{ m}^3/\text{kg}}$$

The mass flow rate of condensate water is expressed as

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = \frac{\dot{\nu}_1}{0.8585} (0.008337 - 0.006065) = 0.002646 \dot{\nu}_1$$

The enthalpy of condensate water is

$$h_{w2} = h_{f@8^\circ\text{C}} = 33.63 \text{ kJ/kg} \quad (\text{Table A-4})$$

An energy balance on the control volume gives

$$\begin{aligned} \dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ \frac{\dot{\nu}_1}{0.8585} (43.05) &= \dot{Q}_{\text{out}} + \frac{\dot{\nu}_1}{0.8585} (23.11) + 0.002646 \dot{\nu}_1 (33.63) \end{aligned} \quad (1)$$

The properties of the R-134a at the inlet of the compressor and the enthalpy at the exit for the isentropic process are (R-134a tables)

$$\begin{aligned} P_{R1} &= 375 \text{ kPa} \left\{ \begin{aligned} h_{R1} &= 254.48 \text{ kJ/kg} \\ s_{R1} &= 0.9278 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right. \\ x_{R1} &= 1 \\ P_{R2} &= 1800 \text{ kPa} \left\{ \begin{aligned} h_{R2,s} &= 286.90 \text{ kJ/kg} \\ s_{R2} &= s_{R1} \end{aligned} \right. \end{aligned}$$

The enthalpies of R-134a at the condenser exit and the throttle exit are

$$\begin{aligned} h_{R3} &= h_{f@1800 \text{ kPa}} = 144.07 \text{ kJ/kg} \\ h_{R4} &= h_{R3} = 144.07 \text{ kJ/kg} \end{aligned}$$

The mass flow rate of the refrigerant can be determined from the expression for the compressor power:

$$\dot{W}_C = \dot{m}_R \frac{h_{R2,s} - h_{R1}}{\eta_C}$$

$$6 \text{ kW} = \dot{m}_R \frac{(286.90 - 254.48) \text{ kJ/kg}}{0.85}$$

$$\dot{m}_R = 0.1573 \text{ kg/s} = 9.439 \text{ kg/min}$$

The rate of heat absorbed by the R-134a in the evaporator is

$$\dot{Q}_{R,\text{in}} = \dot{m}_R (h_{R1} - h_{R4}) = (9.439 \text{ kg/min})(254.48 - 144.07) \text{ kJ/kg} = 1042.1 \text{ kJ/min}$$

The rate of heat lost from the air in the evaporator is absorbed by the refrigerant-134a. That is,  $\dot{Q}_{R,\text{in}} = \dot{Q}_{\text{out}}$ . Then, the volume flow rate of the air at the inlet of the evaporator can be determined from Eq. (1) to be

$$\frac{\dot{V}_1}{0.8474} (43.05) = 1042.1 + \frac{\dot{V}_1}{0.8474} (23.11) + 0.002646 \dot{V}_1 (33.63) \longrightarrow \dot{V}_1 = \mathbf{44.87 \text{ m}^3/\text{min}}$$

**14-95** Air flows through an air conditioner unit. The inlet and exit states are specified. The rate of heat transfer and the mass flow rate of condensate water are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The inlet state of the air is completely specified, and the total pressure is 98 kPa. The properties of the air at the inlet state may be determined from (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$\begin{aligned}h_1 &= 77.88 \text{ kJ/kg dry air} \\ \omega_1 &= 0.01866 \text{ kg H}_2\text{O/kg dry air} \\ \phi_1 &= 0.6721\end{aligned}$$

The partial pressure of water vapor at the exit state is

$$P_{v2} = P_{\text{sat}@ 6.5^\circ\text{C}} = 0.9682 \text{ kPa} \quad (\text{Table A - 4})$$

The saturation pressure at the exit state is

$$P_{g2} = P_{\text{sat}@ 25^\circ\text{C}} = 3.17 \text{ kPa} \quad (\text{Table A - 4})$$

Then, the relative humidity at the exit state becomes

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{0.9682}{3.17} = 0.3054$$

Now, the exit state is also fixed. The properties are obtained from EES to be

$$\begin{aligned}h_2 &= 40.97 \text{ kJ/kg dry air} \\ \omega_2 &= 0.006206 \text{ kg H}_2\text{O/kg dry air} \\ \nu_2 &= 0.8820 \text{ m}^3/\text{kg}\end{aligned}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{\nu}_2}{\nu_2} = \frac{1000 \text{ m}^3/\text{min}}{0.8820 \text{ m}^3/\text{kg}} = 1133.8 \text{ kg/min}$$

The mass flow rate of condensate water is

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = (1133.8 \text{ kg/min})(0.01866 - 0.006206) = 14.12 \text{ kg/min} = \mathbf{847.2 \text{ kg/h}}$$

The enthalpy of condensate water is

$$h_{w2} = h_{f@ 25^\circ\text{C}} = 104.83 \text{ kJ/kg} \quad (\text{Table A - 4})$$

An energy balance on the control volume gives

$$\begin{aligned}\dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (1133.8 \text{ kg/min})(77.88 \text{ kJ/kg}) &= \dot{Q}_{\text{out}} + (1133.8 \text{ kg/min})(40.97 \text{ kJ/kg}) + (14.12 \text{ kg/min})(104.83 \text{ kJ/kg}) \\ \dot{Q}_{\text{out}} &= 40,377 \text{ kJ/min} = \mathbf{672.9 \text{ kW}}\end{aligned}$$

## Evaporative Cooling

**14-96C** In steady operation, the mass transfer process does not have to involve heat transfer. However, a mass transfer process that involves phase change (evaporation, sublimation, condensation, melting etc.) must involve heat transfer. For example, the evaporation of water from a lake into air (mass transfer) requires the transfer of latent heat of water at a specified temperature to the liquid water at the surface (heat transfer).

**14-97C** During evaporation from a water body to air, the latent heat of vaporization will be equal to *convection* heat transfer from the air when *conduction* from the lower parts of the water body to the surface is negligible, and temperature of the surrounding surfaces is at about the temperature of the water surface so that the *radiation* heat transfer is negligible.

**14-98C** Evaporative cooling is the cooling achieved when water evaporates in dry air. It will not work on humid climates.

**14-99** Air is cooled by an evaporative cooler. The exit temperature of the air and the required rate of water supply are to be determined.

**Analysis** (a) From the psychrometric chart (Fig. A-31) at 36°C and 20% relative humidity we read

$$T_{wb1} = 19.5^\circ\text{C}$$

$$\omega_1 = 0.0074 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.887 \text{ m}^3/\text{kg dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \cong T_{wb1} = 19.5^\circ\text{C}$$

At this wet-bulb temperature and 90% relative humidity we read

$$T_2 = 20.5^\circ\text{C}$$

$$\omega_2 = 0.0137 \text{ kg H}_2\text{O / kg dry air}$$

Thus air will be cooled to 20.5°C in this evaporative cooler.

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3/\text{min}}{0.887 \text{ m}^3/\text{kg dry air}} = 4.51 \text{ kg/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\begin{aligned} \dot{m}_{\text{supply}} &= \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a (\omega_2 - \omega_1) \\ &= (4.51 \text{ kg/min})(0.0137 - 0.0074) = \mathbf{0.028 \text{ kg/min}} \end{aligned}$$

**14-100E** Air is cooled by an evaporative cooler. The exit temperature of the air and the required rate of water supply are to be determined.

**Analysis** (a) From the psychrometric chart (Fig. A-31E) at 90°F and 20% relative humidity we read

$$T_{wb1} = 62.8^\circ\text{F}$$

$$\omega_1 = 0.0060 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 14.0 \text{ ft}^3/\text{lbm dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \cong T_{wb1} = 62.8^\circ\text{F}$$

At this wet-bulb temperature and 90% relative humidity we read

$$T_2 = 65^\circ\text{F}$$

$$\omega_2 = 0.0116 \text{ lbm H}_2\text{O/lbm dry air}$$

Thus air will be cooled to 64°F in this evaporative cooler.

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{\nu}_1}{\nu_1} = \frac{150 \text{ ft}^3 / \text{min}}{14.0 \text{ ft}^3 / \text{lbm dry air}} = 10.7 \text{ lbm/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\dot{m}_{\text{supply}} = \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a(\omega_2 - \omega_1) = (10.7 \text{ lbm/min})(0.0116 - 0.0060) = \mathbf{0.06 \text{ lbm/min}}$$

**14-101** Air is cooled by an evaporative cooler. The final relative humidity and the amount of water added are to be determined.

**Analysis** (a) From the psychrometric chart (Fig. A-31) at 32°C and 30% relative humidity we read

$$T_{wb1} = 19.4^{\circ}\text{C}$$

$$\omega_1 = 0.0089 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.877 \text{ m}^3/\text{kg dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \cong T_{wb1} = 19.4^{\circ}\text{C}$$

At this wet-bulb temperature and 22°C temperature we read

$$\phi_2 = 79\%$$

$$\omega_2 = 0.0130 \text{ kg H}_2\text{O/kg dry air}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{\nu}_1}{\nu_1} = \frac{5 \text{ m}^3 / \text{min}}{0.877 \text{ m}^3 / \text{kg dry air}} = 5.70 \text{ kg/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\dot{m}_{\text{supply}} = \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a (\omega_2 - \omega_1) = (5.70 \text{ kg/min})(0.0130 - 0.0089) = \mathbf{0.0234 \text{ kg/min}}$$

**14-102** Air enters an evaporative cooler at a specified state and relative humidity. The lowest temperature that air can attain is to be determined.

**Analysis** From the psychrometric chart (Fig. A-31) at 29°C and 40% relative humidity we read

$$T_{wb1} = 19.3^{\circ}\text{C}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature, which is the lowest temperature that can be obtained in an evaporative cooler. That is,

$$T_{\min} = T_{wb1} = \mathbf{19.3^{\circ}\text{C}}$$

**14-103** Air is first heated in a heating section and then passed through an evaporative cooler. The exit relative humidity and the amount of water added are to be determined.

**Analysis** (a) From the psychrometric chart (Fig. A-31) at 15°C and 60% relative humidity we read

$$\omega_1 = 0.00635 \text{ kg H}_2\text{O} / \text{kg dry air}$$

The specific humidity  $\omega$  remains constant during the heating process. Therefore,  $\omega_2 = \omega_1 = 0.00635$  kg H<sub>2</sub>O / kg dry air. At this  $\omega$  value and 30°C we read  $T_{wb2} = 16.7^\circ\text{C}$ .

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,  $T_{wb3} \cong T_{wb2} = 16.7^\circ\text{C}$ . At this  $T_{wb}$  value and 25°C we read

$$\phi_3 = 42.6\%$$

$$\omega_3 = 0.00840 \text{ kg H}_2\text{O/kg dry air}$$

(b) The amount of water added to the air per unit mass of air is

$$\Delta\omega_{23} = \omega_3 - \omega_2 = 0.00840 - 0.00635 = 0.00205 \text{ kg H}_2\text{O/kg dry air}$$

**14-104E** Desert dwellers often wrap their heads with a water-soaked porous cloth. The temperature of this cloth on a desert with specified temperature and relative humidity is to be determined.

**Analysis** Since the cloth behaves as the wick on a wet bulb thermometer, the temperature of the cloth will become the wet-bulb temperature. According to the psychrometric chart, this temperature is

$$T_2 = T_{wb1} = 73.7^\circ\text{F}$$

This process can be represented by an evaporative cooling process as shown in the figure.

**Adiabatic Mixing of Airstreams**

**14-105C** This will occur when the straight line connecting the states of the two streams on the psychrometric chart crosses the saturation line.

**14-106C** Yes.

**14-107** Two airstreams are mixed steadily. The specific humidity, the relative humidity, the dry-bulb temperature, and the volume flow rate of the mixture are to be determined.

**Assumptions** 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

**Properties** Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 62.7 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0119 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.882 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 31.9 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0079 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_2 = 0.819 \text{ m}^3/\text{kg dry air}$$

**Analysis** The mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{20 \text{ m}^3/\text{min}}{0.882 \text{ m}^3/\text{kg dry air}} = 22.7 \text{ kg/min}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{\nu_2} = \frac{25 \text{ m}^3/\text{min}}{0.819 \text{ m}^3/\text{kg dry air}} = 30.5 \text{ kg/min}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (22.7 + 30.5) \text{ kg/min} = 53.2 \text{ kg/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{22.7}{30.5} = \frac{0.0079 - \omega_3}{\omega_3 - 0.0119} = \frac{31.9 - h_3}{h_3 - 62.7}$$

which yields,

$$\omega_3 = \mathbf{0.0096 \text{ kg H}_2\text{O/kg dry air}}$$

$$h_3 = 45.0 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$T_3 = \mathbf{20.6^\circ\text{C}}$$

$$\phi_3 = \mathbf{63.4\%}$$

$$\nu_3 = 0.845 \text{ m}^3/\text{kg dry air}$$

Finally, the volume flow rate of the mixture is determined from

$$\dot{V}_3 = \dot{m}_{a3} \nu_3 = (53.2 \text{ kg/min})(0.845 \text{ m}^3/\text{kg}) = \mathbf{45.0 \text{ m}^3/\text{min}}$$

**14-108** Two airstreams are mixed steadily. The specific humidity, the relative humidity, the dry-bulb temperature, and the volume flow rate of the mixture are to be determined.

**Assumptions** 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

**Analysis** The properties of each inlet stream are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@32^\circ\text{C}} = (0.40)(4.760 \text{ kPa}) = 1.90 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 90 - 1.90 = 88.10 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(305 \text{ K})}{88.10 \text{ kPa}}$$

$$= 0.994 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.90 \text{ kPa})}{(90 - 1.90) \text{ kPa}}$$

$$= 0.0134 \text{ kg H}_2\text{O/kg dry air}$$

$$\begin{aligned} h_1 &= c_p T_1 + \omega_1 h_{g1} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(32^\circ\text{C}) + (0.0134)(2559.2 \text{ kJ/kg}) \\ &= 66.45 \text{ kJ/kg dry air} \end{aligned}$$

and

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}@12^\circ\text{C}} = (0.90)(1.403 \text{ kPa}) = 1.26 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 90 - 1.26 = 88.74 \text{ kPa}$$

$$\nu_2 = \frac{R_a T_2}{P_{a2}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(285 \text{ K})}{88.74 \text{ kPa}} = 0.922 \text{ m}^3 / \text{kg dry air}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(1.26 \text{ kPa})}{(90 - 1.26) \text{ kPa}} = 0.00883 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(12^\circ\text{C}) + (0.00883)(2522.9 \text{ kJ/kg}) = 34.34 \text{ kJ/kg dry air}$$

Then the mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{\nu}_1}{\nu_1} = \frac{20 \text{ m}^3 / \text{min}}{0.994 \text{ m}^3 / \text{kg dry air}} = 20.12 \text{ kg/min}$$

$$\dot{m}_{a2} = \frac{\dot{\nu}_2}{\nu_2} = \frac{25 \text{ m}^3 / \text{min}}{0.922 \text{ m}^3 / \text{kg dry air}} = 27.11 \text{ kg/min}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (20.12 + 27.11) \text{ kg/min} = 47.23 \text{ kg/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \longrightarrow \frac{20.12}{27.11} = \frac{0.00883 - \omega_3}{\omega_3 - 0.0134} = \frac{34.34 - h_3}{h_3 - 66.45}$$

which yields

$$\omega_3 = \mathbf{0.0108 \text{ kg H}_2\text{O/kg dry air}}$$

$$h_3 = 48.02 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties are determined from

$$h_3 = c_p T_3 + \omega_3 h_{g3} \cong c_p T_3 + \omega_3 (2501.3 + 1.82 T_3)$$

$$48.02 \text{ kJ/kg} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C}) T_3 + (0.0108)(2500.9 + 1.82 T_3) \text{ kJ/kg} \longrightarrow T_3 = \mathbf{20.5^\circ\text{C}}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}}$$

$$0.0108 = \frac{0.622 P_{v3}}{90 - P_{v3}} \longrightarrow P_{v3} = 1.54 \text{ kPa}$$

$$\phi_3 = \frac{P_{v3}}{P_{g3}} = \frac{P_{v3}}{P_{\text{sat}@T_3}} = \frac{1.54 \text{ kPa}}{2.41 \text{ kPa}} = 0.639 \text{ or } \mathbf{63.9\%}$$

Finally,

$$P_{a3} = P_3 - P_{v3} = 90 - 1.54 = 88.46 \text{ kPa}$$

$$\nu_3 = \frac{R_a T_3}{P_{a3}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293.5 \text{ K})}{88.46 \text{ kPa}} = 0.952 \text{ m}^3 / \text{kg dry air}$$

$$\dot{\mathcal{V}}_3 = \dot{m}_{a3} \nu_3 = (47.23 \text{ kg/min})(0.952 \text{ m}^3 / \text{kg}) = \mathbf{45.0 \text{ m}^3 / \text{min}}$$

**14-109E** Two airstreams are mixed steadily. The temperature and the relative humidity of the mixture are to be determined.

**Assumptions** 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

**Properties** Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31E or from EES) to be

$$h_1 = 66.7 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0386 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 14.98 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 14.5 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0023 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_2 = 12.90 \text{ ft}^3/\text{lbm dry air}$$

**Analysis** The mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{3 \text{ ft}^3/\text{s}}{14.98 \text{ ft}^3/\text{lbm dry air}} = 0.2002 \text{ lbm/s}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{\nu_2} = \frac{1 \text{ ft}^3/\text{s}}{12.90 \text{ ft}^3/\text{lbm dry air}} = 0.07755 \text{ lbm/s}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (0.2002 + 0.07755) \text{ lbm/s} = 0.2778 \text{ lbm/s}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{0.2002}{0.07755} = \frac{0.0023 - \omega_3}{\omega_3 - 0.0386} = \frac{14.5 - h_3}{h_3 - 66.7}$$

which yields

$$\omega_3 = 0.0284 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_3 = 52.1 \text{ Btu/lbm dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$T_3 = \mathbf{86.7^\circ\text{F}}$$

$$\phi_3 = 1.0 = \mathbf{100\%}$$

**14-110E** Two airstreams are mixed steadily. The rate of entropy generation is to be determined.

**Assumptions** 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

**Properties** Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or from EES) to be

$$\begin{aligned}h_1 &= 66.7 \text{ Btu/lbm dry air} \\ \omega_1 &= 0.0386 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_1 &= 14.98 \text{ ft}^3/\text{lbm dry air}\end{aligned}$$

and

$$\begin{aligned}h_2 &= 14.5 \text{ Btu/lbm dry air} \\ \omega_2 &= 0.0023 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_2 &= 12.90 \text{ ft}^3/\text{lbm dry air}\end{aligned}$$

The entropies of water vapor in the air streams are

$$\begin{aligned}s_{g1} &= s_g @ 100^\circ\text{F} = 1.9819 \text{ Btu/lbm} \cdot \text{R} \\ s_{g2} &= s_g @ 50^\circ\text{F} = 2.1256 \text{ Btu/lbm} \cdot \text{R}\end{aligned}$$

**Analysis** The mass flow rate of dry air in each stream is

$$\begin{aligned}\dot{m}_{a1} &= \frac{\dot{V}_1}{\nu_1} = \frac{3 \text{ ft}^3/\text{s}}{14.98 \text{ ft}^3/\text{lbm dry air}} = 0.2002 \text{ lbm/s} \\ \dot{m}_{a2} &= \frac{\dot{V}_2}{\nu_2} = \frac{1 \text{ ft}^3/\text{s}}{12.90 \text{ ft}^3/\text{lbm dry air}} = 0.07755 \text{ lbm/s}\end{aligned}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (0.2002 + 0.07755) \text{ lbm/s} = 0.2778 \text{ lbm/s}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\begin{aligned}\frac{\dot{m}_{a1}}{\dot{m}_{a2}} &= \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \\ \frac{0.2002}{0.07755} &= \frac{0.0023 - \omega_3}{\omega_3 - 0.0386} = \frac{14.5 - h_3}{h_3 - 66.7}\end{aligned}$$

which yields

$$\begin{aligned}\omega_3 &= 0.0284 \text{ lbm H}_2\text{O/lbm dry air} \\ h_3 &= 52.1 \text{ Btu/lbm dry air}\end{aligned}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$\begin{aligned}T_3 &= 86.7^\circ\text{F} \\ \phi_3 &= 1.0 = 100\%\end{aligned}$$

The entropy of water vapor in the mixture is

$$s_{g3} = s_g @ 86.7^\circ\text{F} = 2.0168 \text{ Btu/lbm} \cdot \text{R}$$

An entropy balance on the mixing chamber for the water gives

$$\begin{aligned}\Delta \dot{S}_w &= \dot{m}_{a3} \omega_3 s_3 - \dot{m}_{a1} \omega_1 s_1 - \dot{m}_{a2} \omega_2 s_2 \\ &= 0.2778 \times 0.0284 \times 2.0168 - 0.2002 \times 0.0386 \times 1.9819 - 0.07755 \times 0.0023 \times 2.1256 \\ &= 2.169 \times 10^{-4} \text{ Btu/s} \cdot \text{R}\end{aligned}$$

The partial pressures of water vapor and dry air for all three air streams are

$$\begin{aligned}P_{v1} &= \phi_1 P_{g1} = \phi_1 P_{\text{sat}@100^\circ\text{F}} = (0.90)(0.95052 \text{ psia}) = 0.8555 \text{ psia} \\ P_{a1} &= P_1 - P_{v1} = 14.696 - 0.8555 = 13.84 \text{ psia} \\ P_{v2} &= \phi_2 P_{g2} = \phi_2 P_{\text{sat}@50^\circ\text{F}} = (0.30)(0.17812 \text{ psia}) = 0.0534 \text{ psia} \\ P_{a2} &= P_2 - P_{v2} = 14.696 - 0.0534 = 14.64 \text{ psia} \\ P_{v3} &= \phi_3 P_{g3} = \phi_3 P_{\text{sat}@86.7^\circ\text{C}} = (1.0)(0.6298 \text{ psia}) = 0.6298 \text{ psia} \\ P_{a3} &= P_3 - P_{v3} = 14.696 - 0.6298 = 14.07 \text{ psia}\end{aligned}$$

An entropy balance on the mixing chamber for the dry air gives

$$\begin{aligned}\Delta \dot{S}_a &= \dot{m}_{a1}(s_3 - s_1) + \dot{m}_{a2}(s_3 - s_2) \\ &= \dot{m}_{a1} \left( c_p \ln \frac{T_3}{T_1} - R \ln \frac{P_{a3}}{P_{a1}} \right) + \dot{m}_{a2} \left( c_p \ln \frac{T_3}{T_2} - R \ln \frac{P_{a3}}{P_{a2}} \right) \\ &= 0.2002 \left[ (0.240) \ln \frac{546.7}{560} - (0.06855) \ln \frac{14.07}{13.84} \right] + 0.07755 \left[ (0.240) \ln \frac{546.7}{510} - (0.06855) \ln \frac{14.07}{14.64} \right] \\ &= (0.2002)(-0.006899) + (0.07755)(0.01940) = 1.233 \times 10^{-4} \text{ Btu/s} \cdot \text{R}\end{aligned}$$

The rate of entropy generation is then

$$\dot{S}_{\text{gen}} = \Delta \dot{S}_a + \Delta \dot{S}_w = 1.233 \times 10^{-4} + 2.169 \times 10^{-4} = \mathbf{3.402 \times 10^{-4} \text{ Btu/s} \cdot \text{R}}$$

**14-111** Two airstreams are mixed steadily. The mass flow ratio of the two streams for a specified mixture relative humidity and the temperature of the mixture are to be determined.

**Assumptions** 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

**Properties** Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or from EES) to be

$$h_1 = 29.4 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0077 \text{ kg H}_2\text{O/kg dry air}$$

and

$$h_2 = 94.6 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0244 \text{ kg H}_2\text{O/kg dry air}$$

**Analysis** An application of Eq. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams gives

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{0.0244 - \omega_3}{\omega_3 - 0.0077} = \frac{94.6 - h_3}{h_3 - 29.4}$$

This equation cannot be solved directly. An iterative solution is needed. A mixture temperature  $T_3$  is selected. At this temperature and given relative humidity (70%), specific humidity and enthalpy are read from the psychrometric chart. These values are substituted into the above equation. If the equation is not satisfied, a new value of  $T_3$  is selected. This procedure is repeated until the equation is satisfied. Alternatively, EES software can be used. We used the following EES program to get the results:

"Given"

$$P = 101.325 \text{ [kPa]}$$

$$T_1 = 10 \text{ [C]}$$

$$\phi_1 = 1.0$$

$$T_2 = 32 \text{ [C]}$$

$$\phi_2 = 0.80$$

$$\phi_3 = 0.70$$

"Analysis"

$$\text{Fluid\$} = \text{'AirH2O'}$$

"1st stream properties"

$$h_1 = \text{enthalpy}(\text{Fluid\$}, T=T_1, P=P, R=\phi_1)$$

$$w_1 = \text{humrat}(\text{Fluid\$}, T=T_1, P=P, R=\phi_1)$$

"2nd stream properties"

$$h_2 = \text{enthalpy}(\text{Fluid\$}, T=T_2, P=P, R=\phi_2)$$

$$w_2 = \text{humrat}(\text{Fluid\$}, T=T_2, P=P, R=\phi_2)$$

$$(w_2 - w_3)/(w_3 - w_1) = (h_2 - h_3)/(h_3 - h_1)$$

$$\text{Ratio} = (w_2 - w_3)/(w_3 - w_1)$$

"mixture properties"

$$T_3 = \text{temperature}(\text{Fluid\$}, h=h_3, P=P, R=\phi_3)$$

$$h_3 = \text{enthalpy}(\text{Fluid\$}, T=T_3, P=P, R=\phi_3)$$

The solution of this EES program is

$$T_3 = \mathbf{24.0^\circ\text{C}}, \quad \omega_3 = 0.0149 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = 57.6 \text{ kJ/kg dry air}, \quad \frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \mathbf{1.31}$$

**14-112** A stream of warm air is mixed with a stream of saturated cool air. The temperature, the specific humidity, and the relative humidity of the mixture are to be determined.

**Assumptions** 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

**Properties** The properties of each inlet stream are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 110.2 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0272 \text{ kg H}_2\text{O/kg dry air}$$

and

$$h_2 = 50.9 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0129 \text{ kg H}_2\text{O/kg dry air}$$

**Analysis** The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\begin{aligned} \frac{\dot{m}_{a1}}{\dot{m}_{a2}} &= \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \\ \frac{8.0}{6.0} &= \frac{0.0129 - \omega_3}{\omega_3 - 0.0272} = \frac{50.9 - h_3}{h_3 - 110.2} \end{aligned}$$

which yields,

$$(b) \quad \omega_3 = 0.0211 \text{ kg H}_2\text{O / kg dry air}$$

$$h_3 = 84.8 \text{ kJ / kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$(a) \quad T_3 = 30.7^\circ\text{C}$$

$$(c) \quad \phi_3 = 75.1\%$$

**14-113 EES** Problem 14-112 is reconsidered. The effect of the mass flow rate of saturated cool air stream on the mixture temperature, specific humidity, and relative humidity is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

```

## **Wet Cooling Towers**

**14-114C** The working principle of a natural draft cooling tower is based on buoyancy. The air in the tower has a high moisture content, and thus is lighter than the outside air. This light moist air rises under the influence of buoyancy, inducing flow through the tower.

**14-115C** A spray pond cools the warm water by spraying it into the open atmosphere. They require 25 to 50 times the area of a wet cooling tower for the same cooling load.

**14-116** Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

**Assumptions** 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

**Analysis** (a) The mass flow rate of dry air through the tower remains constant ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

**Dry Air Mass Balance:**

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2$$

$$\dot{m}_3 - \dot{m}_4 = \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

Solving for  $\dot{m}_a$ ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31),

$$h_1 = 44.7 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0089 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.849 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 113.5 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0309 \text{ kg H}_2\text{O/kg dry air}$$

From Table A-4,

$$h_3 \cong h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_f @ 26^\circ\text{C} = 109.01 \text{ kJ/kg H}_2\text{O}$$

Substituting,

$$\dot{m}_a = \frac{(60 \text{ kg/s})(167.53 - 109.01) \text{ kJ/kg}}{(113.5 - 44.7) \text{ kJ/kg} - (0.0309 - 0.0089)(109.01) \text{ kJ/kg}} = 52.9 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (52.9 \text{ kg/s})(0.849 \text{ m}^3/\text{kg}) = \mathbf{44.9 \text{ m}^3/\text{s}}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (52.9 \text{ kg/s})(0.0309 - 0.0089) = \mathbf{1.16 \text{ kg/s}}$$

**14-117** Water is cooled by air in a cooling tower. The mass flow rate of dry air is to be determined.

**Assumptions** 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

**Analysis** The mass flow rate of dry air through the tower remains constant ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

**Dry Air Mass Balance:**

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2$$

$$\dot{m}_3 - \dot{m}_4 = \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{steady}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

Solving for  $\dot{m}_a$ ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31),

$$h_1 = 21.8 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.00264 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.820 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 49.3 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0123 \text{ kg H}_2\text{O/kg dry air}$$

From Table A-4,

$$h_3 \cong h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_f @ 22^\circ\text{C} = 92.28 \text{ kJ/kg H}_2\text{O}$$

Substituting,

$$\dot{m}_a = \frac{(5 \text{ kg/s})(125.74 - 92.28) \text{ kJ/kg}}{(49.3 - 21.8) \text{ kJ/kg} - (0.0123 - 0.00264)(92.28) \text{ kJ/kg}} = \mathbf{6.29 \text{ kg/s}}$$

**14-118** Water is cooled by air in a cooling tower. The exergy lost in the cooling tower is to be determined.

**Assumptions** 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

**Analysis** The mass flow rate of dry air through the tower remains constant ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

*Dry Air Mass Balance:*

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

*Water Mass Balance:*

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2$$

$$\dot{m}_3 - \dot{m}_4 = \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}$$

*Energy Balance:*

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{steady}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

Solving for  $\dot{m}_a$ ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31),

$$h_1 = 21.8 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.00264 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.820 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 49.3 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0123 \text{ kg H}_2\text{O/kg dry air}$$

From Table A-4,

$$h_3 \cong h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_f @ 22^\circ\text{C} = 92.28 \text{ kJ/kg H}_2\text{O}$$

Substituting,

$$\dot{m}_a = \frac{(5 \text{ kg/s})(125.74 - 92.28) \text{ kJ/kg}}{(49.3 - 21.8) \text{ kJ/kg} - (0.0123 - 0.00264)(92.28) \text{ kJ/kg}} = 6.29 \text{ kg/s}$$

The mass flow rate of water stream at state 3 per unit mass of dry air is

$$m_3 = \frac{\dot{m}_3}{\dot{m}_a} = \frac{5 \text{ kg water/s}}{6.29 \text{ kg dry air/s}} = 0.7949 \text{ kg water/kg dry air}$$

The mass flow rate of water stream at state 4 per unit mass of dry air is

$$m_4 = m_3 - (\omega_2 - \omega_1) = 0.7949 - (0.0123 - 0.00264) = 0.7852 \text{ kg water/kg dry air}$$

The entropies of water streams are

$$s_3 = s_f @ 30^\circ\text{C} = 0.4368 \text{ kJ/kg} \cdot \text{K}$$

$$s_4 = s_f @ 22^\circ\text{C} = 0.3249 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of water stream is

$$\Delta s_{\text{water}} = m_4 s_4 - m_3 s_3 = 0.7852 \times 0.3249 - 0.7949 \times 0.4368 = -0.09210 \text{ kJ/K} \cdot \text{kg dry air}$$

The entropies of water vapor in the air stream are

$$s_{g1} = s_g @ 15^\circ\text{C} = 8.7803 \text{ kJ/kg} \cdot \text{K}$$

$$s_{g2} = s_g @ 18^\circ\text{C} = 8.7112 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of water vapor in the air stream is

$$\Delta s_{\text{vapor}} = \omega_2 s_{g2} - \omega_1 s_{g1} = 0.0123 \times 8.7112 - 0.00264 \times 8.7803 = 0.08397 \text{ kJ/K} \cdot \text{kg dry air}$$

The partial pressures of water vapor and dry air for air streams are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 15^\circ\text{C}} = (0.25)(1.7057 \text{ kPa}) = 0.4264 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 101.325 - 0.4264 = 100.90 \text{ kPa}$$

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat} @ 18^\circ\text{C}} = (0.95)(2.065 \text{ kPa}) = 1.962 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 101.325 - 1.962 = 99.36 \text{ kPa}$$

The entropy change of dry air is

$$\begin{aligned} \Delta s_a &= s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} \\ &= (1.005) \ln \frac{291}{288} - (0.287) \ln \frac{99.36}{100.90} = 0.01483 \text{ kJ/kg dry air} \end{aligned}$$

The entropy generation in the cooling tower is the total entropy change:

$$s_{\text{gen}} = \Delta s_{\text{water}} + \Delta s_{\text{vapor}} + \Delta s_a = -0.09210 + 0.08397 + 0.01483 = 0.00670 \text{ kJ/K} \cdot \text{kg dry air}$$

Finally, the exergy destruction per unit mass of dry air is

$$x_{\text{dest}} = T_0 s_{\text{gen}} = (288 \text{ K})(0.00670 \text{ kJ/K} \cdot \text{kg dry air}) = \mathbf{1.93 \text{ kJ/kg dry air}}$$

**14-119E** Water is cooled by air in a cooling tower. The relative humidity of the air at the exit and the water's exit temperature are to be determined.

**Assumptions** 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

**Analysis** The mass flow rate of dry air through the tower remains constant ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

**Dry Air Mass Balance:**

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2$$

$$\dot{m}_3 - \dot{m}_4 = \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{no (steady)}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

Solving for  $h_4$ ,

$$h_4 = \frac{\dot{m}_3h_3 - \dot{m}_a(h_2 - h_1)}{\dot{m}_3 - \dot{m}_{\text{makeup}}}$$

From the psychrometric chart (Fig. A-31E),

$$h_1 = 16.8 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.00219 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 13.15 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 37.7 \text{ Btu/lbm dry air}$$

$$\phi_2 = 0.957 = \mathbf{95.7\%}$$

From Table A-4,

$$h_3 \cong h_f @ 100^\circ\text{F} = 68.03 \text{ Btu/lbm H}_2\text{O}$$

Also,

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (7000 / 3600 \text{ lbm/s})(0.018 - 0.00219) = 0.03075 \text{ lbm/s}$$

Substituting,

$$h_4 = \frac{\dot{m}_3h_3 - \dot{m}_a(h_2 - h_1)}{\dot{m}_3 - \dot{m}_{\text{makeup}}} = \frac{(10,000 / 3600)(68.03) - (7000 / 3600)(37.7 - 16.8)}{(10,000 / 3600) - 0.03075} = 53.99 \text{ Btu/lbm}$$

The exit temperature of the water is then (Table A-4E)

$$T_4 = T_{\text{sat}} @ h_f = 53.99 \text{ Btu/lbm} = \mathbf{85.9^\circ\text{F}}$$

**14-120** Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

**Assumptions** 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

**Analysis** (a) The mass flow rate of dry air through the tower remains constant ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

**Dry Air Mass Balance:**

$$\begin{aligned}\sum \dot{m}_{a,i} &= \sum \dot{m}_{a,e} \\ \dot{m}_{a1} &= \dot{m}_{a2} = \dot{m}_a\end{aligned}$$

**Water Mass Balance:**

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \\ \dot{m}_3 + \dot{m}_{a1}\omega_1 &= \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}\end{aligned}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{0 \text{ (steady)}} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

The properties of air at the inlet and the exit are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@20^\circ\text{C}} = (0.70)(2.3392 \text{ kPa}) = 1.637 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 96 - 1.637 = 94.363 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{94.363 \text{ kPa}} = 0.891 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.637 \text{ kPa})}{(96 - 1.637) \text{ kPa}} = 0.0108 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0108)(2537.4 \text{ kJ/kg}) = 47.5 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}@35^\circ\text{C}} = (1.00)(5.6291 \text{ kPa}) = 5.6291 \text{ kPa}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(5.6291 \text{ kPa})}{(96 - 5.6291) \text{ kPa}} = 0.0387 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.0387)(2564.6 \text{ kJ/kg}) = 134.4 \text{ kJ/kg dry air}$$

From Table A-4,

$$h_3 \cong h_{f@40^\circ\text{C}} = 167.53 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_{f@30^\circ\text{C}} = 125.74 \text{ kJ/kg H}_2\text{O}$$

Substituting,

$$\dot{m}_a = \frac{(25 \text{ kg/s})(167.53 - 125.74) \text{ kJ/kg}}{(134.4 - 47.5) \text{ kJ/kg} - (0.0387 - 0.0108)(125.74) \text{ kJ/kg}} = 12.53 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{\mathcal{V}}_1 = \dot{m}_a \nu_1 = (12.53 \text{ kg/s})(0.891 \text{ m}^3 / \text{kg}) = \mathbf{11.2 \text{ m}^3/\text{s}}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a (\omega_2 - \omega_1) = (12.53 \text{ kg/s})(0.0387 - 0.0108) = \mathbf{0.35 \text{ kg/s}}$$

**14-121** A natural-draft cooling tower is used to remove waste heat from the cooling water flowing through the condenser of a steam power plant. The mass flow rate of the cooling water, the volume flow rate of air into the cooling tower, and the mass flow rate of the required makeup water are to be determined.

**Assumptions** 1 All processes are steady-flow and the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

**Analysis** The inlet and exit states of the moist air for the tower are completely specified. The properties may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 50.74 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01085 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8536 \text{ m}^3/\text{kg dry air}$$

$$h_2 = 142.83 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.04112 \text{ kg H}_2\text{O/kg dry air}$$

The enthalpies of cooling water at the inlet and exit of the condenser are (Table A-4)

$$h_{w3} = h_{f@40^\circ\text{C}} = 167.53 \text{ kJ/kg}$$

$$h_{w4} = h_{f@26^\circ\text{C}} = 109.01 \text{ kJ/kg}$$

The steam properties for the condenser are (Steam tables)

$$\left. \begin{array}{l} P_{s1} = 200 \text{ kPa} \\ x_{s1} = 0 \end{array} \right\} h_{s1} = 504.71 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{s2} = 10 \text{ kPa} \\ s_{s2} = 7.962 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{s2} = 2524.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{s3} = 10 \text{ kPa} \\ x_{s1} = 0 \end{array} \right\} h_{s3} = 191.81 \text{ kJ/kg}$$

The mass flow rate of dry air is given by

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_1}{0.8536 \text{ m}^3/\text{kg}}$$

The mass flow rates of vapor at the inlet and exit of the cooling tower are

$$\dot{m}_{v1} = \omega_1 \dot{m}_a = (0.01085) \frac{\dot{V}_1}{0.8536} = 0.01271 \dot{V}_1$$

$$\dot{m}_{v2} = \omega_2 \dot{m}_a = (0.04112) \frac{\dot{V}_1}{0.8536} = 0.04817 \dot{V}_1$$

Mass and energy balances on the cooling tower give

$$\dot{m}_{v1} + \dot{m}_{cw3} = \dot{m}_{v2} + \dot{m}_{cw4}$$

$$\dot{m}_a h_1 + \dot{m}_{cw3} h_{w3} = \dot{m}_a h_2 + \dot{m}_{cw4} h_{w4}$$

The mass flow rate of the makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_{v2} - \dot{m}_{v1} = \dot{m}_{cw3} - \dot{m}_{cw4}$$

An energy balance on the condenser gives

$$0.18 \dot{m}_s h_{s1} + 0.82 \dot{m}_s h_{s2} + \dot{m}_{cw4} h_{w4} + \dot{m}_{\text{makeup}} h_{w4} = \dot{m}_s h_{s3} + \dot{m}_{cw3} h_{w3}$$

Solving all the above equations simultaneously with known and determined values using EES, we obtain

$$\dot{m}_{cw3} = \mathbf{1413 \text{ kg/s}}$$

$$\dot{V}_1 = \mathbf{47,700 \text{ m}^3/\text{min}}$$

$$\dot{m}_{\text{makeup}} = \mathbf{28.19 \text{ kg/s}}$$

## Review Problems

**14-122** Air is compressed by a compressor and then cooled to the ambient temperature at high pressure. It is to be determined if there will be any condensation in the compressed air lines.

**Assumptions** The air and the water vapor are ideal gases.

**Properties** The saturation pressure of water at 20°C is 2.3392 kPa (Table A-4)..

**Analysis** The vapor pressure of air before compression is

$$P_{v1} = \phi_1 P_g = \phi_1 P_{\text{sat @ } 25^\circ\text{C}} = (0.50)(2.3392 \text{ kPa}) = 1.17 \text{ kPa}$$

The pressure ratio during the compression process is  $(800 \text{ kPa})/(92 \text{ kPa}) = 8.70$ . That is, the pressure of air and any of its components increases by 8.70 times. Then the vapor pressure of air after compression becomes

$$P_{v2} = P_{v1} \times (\text{Pressure ratio}) = (1.17 \text{ kPa})(8.70) = 10.2 \text{ kPa}$$

The dew-point temperature of the air at this vapor pressure is

$$T_{\text{dp}} = T_{\text{sat @ } P_{v2}} = T_{\text{sat @ } 10.2 \text{ kPa}} = 46.1^\circ\text{C}$$

which is greater than 20°C. Therefore, part of the moisture in the compressed air will **condense** when air is cooled to 20°C.

**14-123E** The mole fraction of the water vapor at the surface of a lake and the mole fraction of water in the lake are to be determined and compared.

**Assumptions** 1 Both the air and water vapor are ideal gases. 2 Air is weakly soluble in water and thus Henry's law is applicable.

**Properties** The saturation pressure of water at 60°F is 0.2564 psia (Table A-4E). Henry's constant for air dissolved in water at 60°F (289 K) is given in Table 16-2 to be  $H = 62,000$  bar.

**Analysis** The air at the water surface will be saturated. Therefore, the partial pressure of water vapor in the air at the lake surface will simply be the saturation pressure of water at 60°F,

$$P_{\text{vapor}} = P_{\text{sat @60°F}} = 0.2564 \text{ psia}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air at the surface of the lake is determined to be

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{0.2564 \text{ psia}}{13.8 \text{ psia}} = \mathbf{0.0186 \text{ (or 1.86 percent)}}$$

The partial pressure of dry air just above the lake surface is

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 13.8 - 0.2564 = 13.54 \text{ psia}$$

Then the mole fraction of air in the water becomes

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gas side}}}{H} = \frac{13.54 \text{ psia} (1 \text{ atm} / 14.696 \text{ psia})}{62,000 \text{ bar} (1 \text{ atm} / 1.01325 \text{ bar})} = 1.51 \times 10^{-5}$$

which is very small, as expected. Therefore, the mole fraction of water in the lake near the surface is

$$y_{\text{water, liquid side}} = 1 - y_{\text{dry air, liquid side}} = 1 - 1.51 \times 10^{-5} \cong \mathbf{1.0}$$

**Discussion** The concentration of air in water just below the air-water interface is 1.51 moles per 100,000 moles. The amount of air dissolved in water will decrease with increasing depth.

**14-124** The mole fraction of the water vapor at the surface of a lake at a specified temperature is to be determined.

**Assumptions** 1 Both the air and water vapor are ideal gases. 2 Air at the lake surface is saturated.

**Properties** The saturation pressure of water at 18°C is 2.065 kPa (Table A-4).

**Analysis** The air at the water surface will be saturated. Therefore, the partial pressure of water vapor in the air at the lake surface will simply be the saturation pressure of water at 18°C,

$$P_{\text{vapor}} = P_{\text{sat @ 18°C}} = 2.065 \text{ kPa}$$

Assuming both the air and vapor to be ideal gases, the partial pressure and mole fraction of dry air in the air at the surface of the lake are determined to be

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 100 - 2.065 = 97.94 \text{ kPa}$$

$$y_{\text{dry air}} = \frac{P_{\text{dry air}}}{P} = \frac{97.94 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.979} \text{ (or 97.9\%)}$$

Therefore, the mole fraction of dry air is 97.9 percent just above the air-water interface.

**14-125E** A room is cooled adequately by a 7500 Btu/h air-conditioning unit. If the room is to be cooled by an evaporative cooler, the amount of water that needs to be supplied to the cooler is to be determined.

**Assumptions** 1 The evaporative cooler removes heat at the same rate as the air conditioning unit. 2 Water evaporates at an average temperature of 70°F.

**Properties** The enthalpy of vaporization of water at 70°F is 1053.7 Btu/lbm (Table A-4E).

**Analysis** Noting that 1 lbm of water removes 1053.7 Btu of heat as it evaporates, the amount of water that needs to evaporate to remove heat at a rate of 7500 Btu/h is determined from  $\dot{Q} = \dot{m}_{\text{water}} h_{fg}$  to be

$$\dot{m}_{\text{water}} = \frac{\dot{Q}}{h_{fg}} = \frac{7500 \text{ Btu/h}}{1053.7 \text{ Btu/lbm}} = \mathbf{7.12 \text{ lbm/h}}$$

**14-126E** The required size of an evaporative cooler in cfm ( $\text{ft}^3/\text{min}$ ) for an 8-ft high house is determined by multiplying the floor area of the house by 4. An equivalent rule is to be obtained in SI units.

**Analysis** Noting that  $1 \text{ ft} = 0.3048 \text{ m}$  and thus  $1 \text{ ft}^2 = 0.0929 \text{ m}^2$  and  $1 \text{ ft}^3 = 0.0283 \text{ m}^3$ , and noting that a flow rate of  $4 \text{ ft}^3/\text{min}$  is required per  $\text{ft}^2$  of floor area, the required flow rate in SI units per  $\text{m}^2$  of floor area is determined to

$$\begin{aligned} 1 \text{ ft}^2 &\leftrightarrow 4 \text{ ft}^3 / \text{min} \\ 0.0929 \text{ m}^2 &\leftrightarrow 4 \times 0.0283 \text{ m}^3 / \text{min} \\ 1 \text{ m}^2 &\leftrightarrow 1.22 \text{ m}^3 / \text{min} \end{aligned}$$

Therefore, a flow rate of **1.22  $\text{m}^3/\text{min}$**  is required per  $\text{m}^2$  of floor area.

**14-127** A cooling tower with a cooling capacity of 440 kW is claimed to evaporate 15,800 kg of water per day. It is to be determined if this is a reasonable claim.

**Assumptions** 1 Water evaporates at an average temperature of  $30^\circ\text{C}$ . 2 The coefficient of performance of the air-conditioning unit is  $\text{COP} = 3$ .

**Properties** The enthalpy of vaporization of water at  $30^\circ\text{C}$  is  $2429.8 \text{ kJ/kg}$  (Table A-4).

**Analysis** Using the definition of COP, the electric power consumed by the air conditioning unit when running is

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_{\text{cooling}}}{\text{COP}} = \frac{440 \text{ kW}}{3} = 146.7 \text{ kW}$$

Then the rate of heat rejected at the cooling tower becomes

$$\dot{Q}_{\text{rejected}} = \dot{Q}_{\text{cooling}} + \dot{W}_{\text{in}} = 440 + 146.7 = 586.7 \text{ kW}$$

Noting that 1 kg of water removes  $2429.8 \text{ kJ}$  of heat as it evaporates, the amount of water that needs to evaporate to remove heat at a rate of  $586.7 \text{ kW}$  is determined from  $\dot{Q}_{\text{rejected}} = \dot{m}_{\text{water}} h_{fg}$  to be

$$\dot{m}_{\text{water}} = \frac{\dot{Q}_{\text{rejected}}}{h_{fg}} = \frac{586.7 \text{ kJ/s}}{2429.8 \text{ kJ/kg}} = 0.2415 \text{ kg/s} = 869.3 \text{ kg/h} = 20,860 \text{ kg/day}$$

In practice, the air-conditioner will run intermittently rather than continuously at the rated power, and thus the water use will be less. Therefore, the claim amount of 15,800 kg per day is **reasonable**.

**14-128** Air is cooled by evaporating water into this air. The amount of water required and the cooling produced are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 64.0 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0092 \text{ kg H}_2\text{O/kg dry air}$$

and

$$h_2 = 66.0 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0160 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 20^\circ\text{C} = 83.92 \text{ kJ/kg} \quad (\text{Table A-4})$$

**Analysis** The amount of moisture in the air increases due to humidification ( $\omega_2 > \omega_1$ ). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\Delta\omega = \omega_2 - \omega_1 = 0.0160 - 0.0092 = \mathbf{0.0068 \text{ kg H}_2\text{O/kg dry air}}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta\dot{E}_{\text{system}} \stackrel{\phi_0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 + \dot{m}_w h_w - \dot{m}_{a2}h_2 = \dot{m}_a(h_1 - h_2) + \dot{m}_w h_w$$

$$q_{\text{out}} = h_1 - h_2 + (\omega_2 - \omega_1)h_w$$

$$= (64.0 - 66.0) \text{ kJ/kg} + (0.0068)(83.92)$$

$$= \mathbf{-1.43 \text{ kJ/kg dry air}}$$

The negative sign shows that the heat is actually transferred to the system.

**14-129** Air is humidified adiabatically by evaporating water into this air. The temperature of the air at the exit is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 64.0 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0092 \text{ kg H}_2\text{O/kg dry air}$$

and

$$h_w \cong h_f @ 20^\circ\text{C} = 83.92 \text{ kJ/kg} \quad (\text{Table A-4})$$

**Analysis** The amount of moisture in the air increases due to humidification ( $\omega_2 > \omega_1$ ). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

*Water Mass Balance:*

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w \\ \dot{m}_w &= \dot{m}_a(\omega_2 - \omega_1) \end{aligned}$$

*Energy Balance:*

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0 \text{ (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_{a1}h_1 + \dot{m}_w h_w &= \dot{m}_{a2}h_2 \\ \dot{m}_w h_w &= \dot{m}_a(h_2 - h_1) \\ (\omega_2 - \omega_1)h_w &= h_2 - h_1 \end{aligned}$$

Substituting,

$$(\omega_2 - 0.0092)(83.92) = h_2 - 64.0$$

The solution of this equation requires a trial-error method. An air exit temperature is assumed. At this temperature and given relative humidity, the enthalpy and specific humidity values are obtained from psychrometric chart and substituted into this equation. If the equation is not satisfied, a new value of exit temperature is assumed and this continues until the equation is satisfied. Alternatively, an equation solver such as EES may be used for the direct results. We used the following EES program.

"Given"

P=101.325 "[kPa]"

T\_1=40 "[C]"

phi\_1=0.20

phi\_2=0.80

"Analysis"

Fluid1\$='AirH2O'

Fluid2\$='steam\_iapws'

h\_1=enthalpy(Fluid1\$, T=T\_1, R=phi\_1, P=P)

w\_1=humrat(Fluid1\$, T=T\_1, R=phi\_1, P=P)

h\_2=enthalpy(Fluid1\$, T=T\_2, R=phi\_2, P=P)

```
w_2=humrat(Fluid1$, T=T_2, R=phi_2, P=P)
h_w=enthalpy(Fluid2$, T=20, x=0)
q=0
q=h_1-h_2+(w_2-w_1)*h_w
```

The results of these equations are

$$T_2 = \mathbf{24.6^\circ\text{C}}$$

$$h_2 = 64.56 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.01564 \text{ kg H}_2\text{O/kg dry air}$$

**14-130E** Air is cooled and dehumidified at constant pressure. The rate of cooling and the minimum humid air temperature required to meet this cooling requirement are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 50.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0263 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 14.44 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 28.2 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit. Then,

$$h_w \cong h_f @ 82.5^\circ\text{F} = 50.56 \text{ Btu/lbm} \quad (\text{Table A-4})$$

**Analysis** The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The mass of air is

$$m_a = \frac{\nu_1}{\nu_1} = \frac{1000 \text{ ft}^3}{14.44 \text{ ft}^3 / \text{lbm dry air}} = 69.25 \text{ lbm}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$m_w = m_a(\omega_1 - \omega_2) = (69.25 \text{ kg})(0.0263 - 0.0093) = 1.177 \text{ lbm}$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \quad \phi^0(\text{steady}) = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$Q_{\text{out}} = m_a(h_1 - h_2) - m_w h_w$$

$$\begin{aligned} Q_{\text{out}} &= (69.25 \text{ kg})(50.6 - 28.2) \text{ Btu/lbm} - (1.177 \text{ lbm})(50.56 \text{ Btu/lbm}) \\ &= \mathbf{1492 \text{ Btu}} \end{aligned}$$

For the desired dehumidification, the air at the exit should be saturated with a specific humidity of 0.0093 lbm water/lbm dry air. That is,

$$\phi_2 = 1.0$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

The temperature of the air at this state is the minimum air temperature required during this process:

$$T_2 = \mathbf{55.2^\circ\text{F}}$$

**14-131E** Air is cooled and dehumidified at constant pressure by a simple ideal vapor-compression refrigeration system. The system's COP is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 50.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0263 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 14.44 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 28.2 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

For the desired dehumidification, the air at the exit should be saturated with a specific humidity of 0.0093 lbm water/lbm dry air. That is,

$$\phi_2 = 1.0$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

The temperature of the air at this state is the minimum air temperature required during this process:

$$T_{2,\min} = 55.2^\circ\text{F}$$

From the problem statement, the properties of R-134a at various states are (Tables A-11E through A-13E or from EES):

$$\left. \begin{array}{l} T_1 = 55.2 - 10 = 45.2^\circ\text{F} \\ P_2 = P_{\text{sat}} @ 45.2^\circ\text{F} = 55 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 55 \text{ psia} = 109.49 \text{ Btu/lbm} \\ s_1 = s_g @ 55 \text{ psia} = 0.22156 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} T_{\text{sat}} = 90 + 19.5 = 109.5^\circ\text{F} \\ P_2 = P_{\text{sat}} @ 109.5^\circ\text{F} = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_2 = 119.01 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 160 \text{ psia} = 48.52 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 48.52 \text{ Btu/lbm} \quad (\text{throttling})$$

The COP of this system is then

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{109.49 - 48.52}{119.01 - 109.49} = \mathbf{6.40}$$

**14-132E** Air at a specified state is heated to a specified temperature. The relative humidity after the heating is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** There is no correspondence of inlet state from the psychrometric chart. Therefore, we have to use EES psychrometric functions to obtain the specific humidity:

$$\omega_1 = 0.0023 \text{ lbm H}_2\text{O/lbm dry air}$$

As the outside air infiltrates into the dacha, it does not gain or lose any water. Therefore the humidity ratio inside the dacha is the same as that outside,

$$\omega_2 = \omega_1 = 0.0023 \text{ lbm H}_2\text{O/lbm dry air}$$

From EES or Fig. A-31E, at this humidity ratio and the temperature inside the dacha gives

$$\phi_2 = 0.146 = \mathbf{14.6\%}$$

**14-133E** Air is humidified by evaporating water into this air. The amount of heating is to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 19.3 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0023 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 13.40 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 27.1 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0094 \text{ lbm H}_2\text{O/lbm dry air}$$

Also,

$$h_w \cong h_f @ 60^\circ\text{F} = 28.08 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

**Analysis** The amount of moisture in the air increases due to humidification ( $\omega_2 > \omega_1$ ). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

**Water Mass Balance:**

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

**Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi 0 (\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i + \dot{Q}_{\text{in}} = \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{in}} = \dot{m}_{a2}h_2 - \dot{m}_{a1}h_1 - \dot{m}_w h_w = \dot{m}_a (h_2 - h_1) - \dot{m}_w h_w$$

$$q_{\text{in}} = h_2 - h_1 - (\omega_2 - \omega_1)h_w$$

$$= (27.1 - 19.3) \text{ Btu/lbm} - (0.0094 - 0.0023)(28.08)$$

$$= 7.59 \text{ Btu/lbm dry air}$$

The mass of air that has to be humidified is

$$m_a = \frac{\nu}{\nu_1} = \frac{16,000 \text{ ft}^3}{13.40 \text{ ft}^3/\text{lbm dry air}} = 1194 \text{ lbm dry air}$$

The total heat requirement is then

$$Q_{\text{in}} = m_a q_{\text{in}} = (1194 \text{ lbm dry air})(7.59 \text{ Btu/lbm dry air}) = \mathbf{9062 \text{ Btu}}$$

**14-134E** It is estimated that 190,000 barrels of oil would be saved per day if the thermostat setting in residences in summer were raised by 6°F (3.3°C). The amount of money that would be saved per year is to be determined.

**Assumptions** The average cooling season is given to be 120 days, and the cost of oil to be \$20/barrel.

**Analysis** The amount of money that would be saved per year is determined directly from

$$(190,000 \text{ barrel/day})(120 \text{ days/year})(\$20/\text{barrel}) = \mathbf{\$1,596,000,000}$$

Therefore, the proposed measure will save more than one and half billion dollars a year.

**14-135** Shading the condenser can reduce the air-conditioning costs by up to 10 percent. The amount of money shading can save a homeowner per year during its lifetime is to be determined.

**Assumptions** It is given that the annual air-conditioning cost is \$500 a year, and the life of the air-conditioning system is 20 years.

**Analysis** The amount of money that would be saved per year is determined directly from

$$(\$500/\text{year})(20 \text{ years})(0.10) = \mathbf{\$1000}$$

Therefore, the proposed measure will save about \$1000 during the lifetime of the system.

**14-136** A tank contains saturated air at a specified state. The mass of the dry air, the specific humidity, and the enthalpy of the air are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) The air is saturated, thus the partial pressure of water vapor is equal to the saturation pressure at the given temperature,

$$P_v = P_g = P_{\text{sat}@25^\circ\text{C}} = 3.1698 \text{ kPa}$$

$$P_a = P - P_v = 97 - 3.1698 = 93.83 \text{ kPa}$$

Treating air as an ideal gas,

$$m_a = \frac{P_a V}{R_a T} = \frac{(93.83 \text{ kPa})(3 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(298 \text{ K})} = \mathbf{3.29 \text{ kg}}$$

|                                                           |
|-----------------------------------------------------------|
| $3 \text{ m}^3$<br>$25^\circ\text{C}$<br>$97 \text{ kPa}$ |
|-----------------------------------------------------------|

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(3.1698 \text{ kPa})}{(97 - 3.1698) \text{ kPa}} = \mathbf{0.0210 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$h = h_a + \omega h_v \cong c_p T + \omega h_g$$

$$= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.0210)(2546.5 \text{ kJ/kg})$$

$$= \mathbf{78.6 \text{ kJ/kg dry air}}$$

**14-137 EES** Problem 14-136 is reconsidered. The properties of the air at the initial state are to be determined and the effects of heating the air at constant volume until the pressure is 110 kPa is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

**"Input Data:"**

| 109                     | 90.65                   |
| 110                     | 98.2                    |

**14-138E** Air at a specified state and relative humidity flows through a circular duct. The dew-point temperature, the volume flow rate of air, and the mass flow rate of dry air are to be determined.

**Assumptions** The air and the water vapor are ideal gases.

**Analysis** (a) The vapor pressure of air is

$$P_v = \phi P_g = \phi P_{\text{sat @ } 60^\circ\text{F}} = (0.50)(0.2564 \text{ psia}) = 0.128 \text{ psia}$$

Thus the dew-point temperature of the air is

$$T_{\text{dp}} = T_{\text{sat @ } P_v} = T_{\text{sat @ } 0.128 \text{ psia}} = \mathbf{41.3^\circ\text{F}} \text{ (from EES)}$$

(b) The volume flow rate is determined from

$$\dot{V} = VA = V \frac{\pi D^2}{4} = (50 \text{ ft/s}) \left( \frac{\pi \times (8/12 \text{ ft})^2}{4} \right) = \mathbf{17.45 \text{ ft}^3/\text{s}}$$

(c) To determine the mass flow rate of dry air, we first need to calculate its specific volume,

$$P_a = P - P_v = 15 - 0.128 = 14.872 \text{ psia}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(520 \text{ R})}{14.872 \text{ psia}} = 12.95 \text{ ft}^3 / \text{lbm dry air}$$

Thus,

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{17.45 \text{ ft}^3 / \text{s}}{12.95 \text{ ft}^3 / \text{lbm dry air}} = \mathbf{1.35 \text{ lbm/s}}$$

**14-139** Air enters a cooling section at a specified pressure, temperature, and relative humidity. The temperature of the air at the exit and the rate of heat transfer are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The amount of moisture in the air also remains constant ( $\omega_1 = \omega_2$ ) as it flows through the cooling section since the process involves no humidification or dehumidification. The total pressure is 97 kPa. The properties of the air at the inlet state are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 35^\circ\text{C} = (0.3)(5.629 \text{ kPa}) = 1.69 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 97 - 1.69 = 95.31 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(308 \text{ K})}{95.31 \text{ kPa}}$$

$$= 0.927 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.69 \text{ kPa})}{(97 - 1.69) \text{ kPa}} = 0.0110 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.0110)(2564.6 \text{ kJ/kg}) = 63.44 \text{ kJ/kg dry air}$$

The air at the final state is saturated and the vapor pressure during this process remains constant. Therefore, the exit temperature of the air must be the dew-point temperature,

$$T_{\text{dp}} = T_{\text{sat}} @ P_v = T_{\text{sat}} @ 1.69 \text{ kPa} = \mathbf{14.8^\circ\text{C}}$$

(b) The enthalpy of the air at the exit is

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(14.8^\circ\text{C}) + (0.0110)(2528.1 \text{ kJ/kg}) = 42.78 \text{ kJ/kg dry air}$$

Also

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{6 \text{ m}^3 / \text{s}}{0.927 \text{ m}^3 / \text{kg dry air}} = 6.47 \text{ kg/min}$$

Then the rate of heat transfer from the air in the cooling section becomes

$$\dot{Q}_{\text{out}} = \dot{m}_a (h_1 - h_2) = (6.47 \text{ kg/min})(63.44 - 42.78) \text{ kJ/kg} = \mathbf{134 \text{ kJ/min}}$$

**14-140** The outdoor air is first heated and then humidified by hot steam in an air-conditioning system. The rate of heat supply in the heating section and the mass flow rate of the steam required in the humidifying section are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Properties** The amount of moisture in the air also remains constant as it flows through the heating section ( $\omega_1 = \omega_2$ ), but increases in the humidifying section ( $\omega_3 > \omega_2$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 17.7 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0030 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$\nu_1 = 0.807 \text{ m}^3/\text{kg dry air}$$

$$h_2 = 29.8 \text{ kJ/kg dry air}$$

$$\omega_2 = \omega_1 = 0.0030 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = 52.9 \text{ kJ/kg dry air}$$

$$\omega_3 = 0.0109 \text{ kg H}_2\text{O/kg dry air}$$

**Analysis (a)** The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{22 \text{ m}^3/\text{min}}{0.807 \text{ m}^3/\text{kg}} = 27.3 \text{ kg/min}$$

Then the rate of heat transfer to the air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a(h_2 - h_1) = (27.3 \text{ kg/min})(29.8 - 17.7) \text{ kJ/kg} = \mathbf{330.3 \text{ kJ/min}}$$

**(b)** The conservation of mass equation for water in the humidifying section can be expressed as

$$\dot{m}_{a2}\omega_2 + \dot{m}_w = \dot{m}_{a3}\omega_3 \quad \text{or} \quad \dot{m}_w = \dot{m}_a(\omega_3 - \omega_2)$$

Thus,

$$\dot{m}_w = (27.3 \text{ kg/min})(0.0109 - 0.0030) = \mathbf{0.216 \text{ kg/min}}$$

**14-141** Air is cooled and dehumidified in an air-conditioning system with refrigerant-134a as the working fluid. The rate of dehumidification, the rate of heat transfer, and the mass flow rate of the refrigerant are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The saturation pressure of water at 30°C is 4.2469 kPa. Then the dew point temperature of the incoming air stream at 30°C becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.7 \times 4.2469 \text{ kPa}} = 24^\circ\text{C}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The mass flow rate of dry air remains constant during the entire process, but the amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 78.3 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0188 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.885 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 57.5 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O/kg dry air}$$

Also,  $h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg}$  (Table A-4)

$$\text{Then, } \dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3/\text{min}}{0.885 \text{ m}^3/\text{kg dry air}} = 4.52 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the refrigerant),

$$\text{Water Mass Balance: } \sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (4.52 \text{ kg/min})(0.0188 - 0.0147) = \mathbf{0.0185 \text{ kg/min}}$$

(b) **Energy Balance:**

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e \longrightarrow \dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (4.52 \text{ kg/min})(78.3 - 57.5) \text{ kJ/kg} - (0.0185 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{92.5 \text{ kJ/min}}$$

(c) The inlet and exit enthalpies of the refrigerant are

$$h_3 = h_g + x_3 h_{fg} = 88.82 + 0.2 \times 176.21 = 124.06 \text{ kJ/kg}$$

$$h_4 = h_g @ 700 \text{ kPa} = 265.03 \text{ kJ/kg}$$

Noting that the heat lost by the air is gained by the refrigerant, the mass flow rate of the refrigerant becomes

$$\dot{Q}_R = \dot{m}_R(h_4 - h_3) \rightarrow \dot{m}_R = \frac{\dot{Q}_R}{h_4 - h_3} = \frac{92.5 \text{ kJ/min}}{(265.03 - 124.06) \text{ kJ/kg}} = \mathbf{0.66 \text{ kg/min}}$$

**14-142** Air is cooled and dehumidified in an air-conditioning system with refrigerant-134a as the working fluid. The rate of dehumidification, the rate of heat transfer, and the mass flow rate of the refrigerant are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** The dew point temperature of the incoming air stream at 30°C is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@30^\circ\text{C}} = (0.7)(4.247 \text{ kPa}) = 2.973 \text{ kPa}$$

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@2.973 \text{ kPa}} = 24^\circ\text{C}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The amount of moisture in the air decreases due to dehumidification ( $\omega_2 < \omega_1$ ). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. The properties of the air at both states are determined to be

$$P_{a1} = P_1 - P_{v1} = 95 - 2.97 = 92.03 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(303 \text{ K})}{92.03 \text{ kPa}} = 0.945 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(2.97 \text{ kPa})}{(95 - 2.97) \text{ kPa}} = 0.0201 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.0201)(2555.6 \text{ kJ/kg}) = 81.50 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = (1.00)P_{\text{sat}@20^\circ\text{C}} = 2.3392 \text{ kPa}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(2.3392 \text{ kPa})}{(95 - 2.3392) \text{ kPa}} = 0.0157 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0157)(2537.4 \text{ kJ/kg}) = 59.94 \text{ kJ/kg dry air}$$

Also,  $h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg}$  (Table A-4)

Then,

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3 / \text{min}}{0.945 \text{ m}^3 / \text{kg dry air}} = 4.23 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the refrigerant),

**Water Mass Balance:**  $\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (4.23 \text{ kg/min})(0.0201 - 0.0157) = \mathbf{0.0186 \text{ kg/min}}$$

(b) *Energy Balance:*

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no}}{\text{steady}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e \longrightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (4.23 \text{ kg/min})(81.50 - 59.94) \text{ kJ/kg} - (0.0186 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{89.7 \text{ kJ/min}}$$

(c) The inlet and exit enthalpies of the refrigerant are

$$h_3 = h_g + x_3 h_{fg} = 88.82 + 0.2 \times 176.21 = 124.06 \text{ kJ/kg}$$

$$h_4 = h_g @ 700 \text{ kPa} = 265.03 \text{ kJ/kg}$$

Noting that the heat lost by the air is gained by the refrigerant, the mass flow rate of the refrigerant is determined from

$$\dot{Q}_R = \dot{m}_R (h_4 - h_3)$$

$$\dot{m}_R = \frac{\dot{Q}_R}{h_4 - h_3} = \frac{89.7 \text{ kJ/min}}{(265.03 - 124.06) \text{ kJ/kg}} = \mathbf{0.636 \text{ kg/min}}$$

**14-143** Air is heated and dehumidified in an air-conditioning system consisting of a heating section and an evaporative cooler. The temperature and relative humidity of the air when it leaves the heating section, the rate of heat transfer in the heating section, and the rate of water added to the air in the evaporative cooler are to be determined.

**Assumptions** **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** (a) Assuming the wet-bulb temperature of the air remains constant during the evaporative cooling process, the properties of air at various states are determined from the psychrometric chart (Fig. A-31) to be

$$\begin{aligned}
 & \left. \begin{array}{l} T_1 = 10^\circ\text{C} \\ \phi_1 = 70\% \end{array} \right\} \begin{array}{l} h_1 = 23.5 \text{ kJ/kg dry air} \\ \omega_1 = 0.00532 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 = 0.810 \text{ m}^3/\text{kg} \end{array} \\
 & \left. \begin{array}{l} \omega_2 = \omega_1 \\ T_{\text{wb}2} = T_{\text{wb}3} \end{array} \right\} \begin{array}{l} T_2 = 28.3^\circ\text{C} \\ \phi_2 = 22.3\% \\ h_2 \cong h_3 = 42.3 \text{ kJ/kg dry air} \end{array} \\
 & \left. \begin{array}{l} T_3 = 20^\circ\text{C} \\ \phi_3 = 60\% \end{array} \right\} \begin{array}{l} h_3 = 42.3 \text{ kJ/kg dry air} \\ \omega_3 = 0.00875 \text{ kg H}_2\text{O/kg dry air} \\ T_{\text{wb}3} = 15.1^\circ\text{C} \end{array}
 \end{aligned}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{30 \text{ m}^3/\text{min}}{0.810 \text{ m}^3/\text{kg dry air}} = 37.0 \text{ kg/min}$$

Then the rate of heat transfer to air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (37.0 \text{ kg/min})(42.3 - 23.5) \text{ kJ/kg} = \mathbf{696 \text{ kJ/min}}$$

(c) The rate of water added to the air in evaporative cooler is

$$\dot{m}_{\text{w, added}} = \dot{m}_{\text{w}3} - \dot{m}_{\text{w}2} = \dot{m}_a (\omega_3 - \omega_2) = (37.0 \text{ kg/min})(0.00875 - 0.00532) = \mathbf{0.127 \text{ kg/min}}$$

**14-144 EES** Problem 14-143 is reconsidered. The effect of total pressure in the range 94 to 104 kPa on the results required in the problem is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

```
P=101.325 [kPa]
Tdb[1]=10 [C]

**14-145** Air is heated and dehumidified in an air-conditioning system consisting of a heating section and an evaporative cooler. The temperature and relative humidity of the air when it leaves the heating section, the rate of heat transfer in the heating section, and the rate at which water is added to the air in the evaporative cooler are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis (a)** Assuming the wet-bulb temperature of the air remains constant during the evaporative cooling process, the properties of air at various states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@10^\circ\text{C}} = (0.70)(1.2281 \text{ kPa}) = 0.86 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 96 - 0.86 = 95.14 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(283 \text{ K})}{95.14 \text{ kPa}} = 0.854 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.86 \text{ kPa})}{(96 - 0.86) \text{ kPa}} = 0.00562 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(10^\circ\text{C}) + (0.00562)(2519.2 \text{ kJ/kg}) = 24.21 \text{ kJ/kg dry air}$$

and

$$P_{v3} = \phi_3 P_{g3} = \phi_3 P_{\text{sat}@20^\circ\text{C}} = (0.60)(2.3392 \text{ kPa}) = 1.40 \text{ kPa}$$

$$P_{a3} = P_3 - P_{v3} = 96 - 1.40 = 94.60 \text{ kPa}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}} = \frac{0.622(1.40 \text{ kPa})}{(96 - 1.40) \text{ kPa}} = 0.00923 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = c_p T_3 + \omega_3 h_{g3} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.00921)(2537.4 \text{ kJ/kg}) = 43.52 \text{ kJ/kg dry air}$$

Also,

$$h_2 \cong h_3 = 43.52 \text{ kJ/kg}$$

$$\omega_2 = \omega_1 = 0.00562 \text{ kg H}_2\text{O/kg dry air}$$

Thus,

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82 T_2) = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C}) T_2 + (0.00562)(2500.9 + 1.82 T_2)$$

Solving for  $T_2$ ,

$$T_2 = 29.0^\circ\text{C} \longrightarrow P_{g2} = P_{\text{sat}@29^\circ\text{C}} = 4.013 \text{ kPa}$$

$$\text{Thus, } \phi_2 = \frac{\omega_2 P_2}{(0.622 + \omega_2) P_{g2}} = \frac{(0.00562)(96)}{(0.622 + 0.00562)(4.013)} = 0.214 \text{ or } 21.4\%$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{30 \text{ m}^3 / \text{min}}{0.854 \text{ m}^3 / \text{kg dry air}} = 35.1 \text{ kg/min}$$

Then the rate of heat transfer to air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (35.1 \text{ kg/min})(43.52 - 24.21) \text{ kJ/kg} = 679 \text{ kJ/min}$$

(c) The rate of water addition to the air in evaporative cooler is

$$\dot{m}_{w, \text{added}} = \dot{m}_{w3} - \dot{m}_{w2} = \dot{m}_a (\omega_3 - \omega_2) = (35.1 \text{ kg/min})(0.00923 - 0.00562) = 0.127 \text{ kg/min}$$

**14-146 [Also solved by EES on enclosed CD]** Waste heat from the cooling water is rejected to air in a natural-draft cooling tower. The mass flow rate of the cooling water, the volume flow rate of air, and the mass flow rate of the required makeup water are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

**Analysis** (a) The mass flow rate of dry air through the tower remains constant ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation is made up later in the cycle using water at 27°C. Applying the mass balance and the energy balance equations yields

**Dry Air Mass Balance:**

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

**Water Mass Balance:**

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \\ \dot{m}_3 + \dot{m}_{a1}\omega_1 &= \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

**Energy Balance:**

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{\approx} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3 \\ 0 &= \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3 \end{aligned}$$

Solving for  $\dot{m}_a$ ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31),

$$\begin{aligned} h_1 &= 50.8 \text{ kJ/kg dry air} \\ \omega_1 &= 0.0109 \text{ kg H}_2\text{O/kg dry air} \\ \omega_1 &= 0.854 \text{ m}^3/\text{kg dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 143.0 \text{ kJ/kg dry air} \\ \omega_2 &= 0.0412 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

From Table A-4,

$$\begin{aligned} h_3 &\cong h_f @ 42^\circ\text{C} = 175.90 \text{ kJ/kg H}_2\text{O} \\ h_4 &\cong h_f @ 27^\circ\text{C} = 113.19 \text{ kJ/kg H}_2\text{O} \end{aligned}$$

Substituting

$$\dot{m}_a = \frac{\dot{m}_3(175.90 - 113.19) \text{ kJ/kg}}{(143.0 - 50.8) \text{ kJ/kg} - (0.0412 - 0.0109)(113.25) \text{ kJ/kg}} = 0.706 \dot{m}_3$$

The mass flow rate of the cooling water is determined by applying the steady flow energy balance equation on the cooling water,

$$\begin{aligned}\dot{Q}_{\text{waste}} &= \dot{m}_3 h_3 - (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 = \dot{m}_3 h_3 - [\dot{m}_3 - \dot{m}_a (\omega_2 - \omega_1)] h_4 \\ &= \dot{m}_3 h_3 - \dot{m}_3 [1 - 0.706(0.0412 - 0.0109)] h_4 = \dot{m}_3 (h_3 - 0.9786 h_4) \\ 50,000 \text{ kJ/s} &= \dot{m}_3 (175.90 - 0.9786 \times 113.19) \text{ kJ/kg} \longrightarrow \dot{m}_3 = \mathbf{768.1 \text{ kg/s}}\end{aligned}$$

and

$$\dot{m}_a = 0.706 \dot{m}_3 = (0.706)(768.1 \text{ kg/s}) = 542.3 \text{ kg/s}$$

(b) Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (542.3 \text{ kg/s})(0.854 \text{ m}^3 / \text{kg}) = \mathbf{463.1 \text{ m}^3/\text{s}}$$

(c) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a (\omega_2 - \omega_1) = (542.3 \text{ kg/s})(0.0412 - 0.0109) = \mathbf{16.4 \text{ kg/s}}$$

**14-147 EES** Problem 14-146 is reconsidered. The effect of air inlet wet-bulb temperature on the required air volume flow rate and the makeup water flow rate is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**14-148** Atmospheric air enters an air-conditioning system at a specified pressure, temperature, and relative humidity. The heat transfer, the rate of condensation of water, and the mass flow rate of the refrigerant are to be determined.

**Assumptions 1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ( $\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$ ). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

**Analysis** The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states may be determined from the psychrometric chart (Figure A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 78.24 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01880 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8847 \text{ m}^3/\text{kg dry air}$$

$$h_2 = 27.45 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.002885 \text{ kg H}_2\text{O/kg dry air}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3/\text{min}}{0.8847 \text{ m}^3} = 4.521 \text{ kg/min}$$

The mass flow rates of vapor at the inlet and exit are

$$\dot{m}_{v1} = \omega_1 \dot{m}_a = (0.01880)(4.521 \text{ kg/min}) = 0.0850 \text{ kg/min}$$

$$\dot{m}_{v2} = \omega_2 \dot{m}_a = (0.002885)(4.521 \text{ kg/min}) = 0.01304 \text{ kg/min}$$

An energy balance on the control volume gives

$$\dot{m}_a h_1 = \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2}$$

where the the enthalpy of condensate water is

$$h_{w2} = h_{f@20^\circ\text{C}} = 83.91 \text{ kJ/kg} \quad (\text{Table A-4})$$

and the rate of condensation of water vapor is

$$\dot{m}_w = \dot{m}_{v1} - \dot{m}_{v2} = 0.0850 - 0.01304 = \mathbf{0.07196 \text{ kg/min}}$$

Substituting,

$$\begin{aligned} \dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (4.521 \text{ kg/min})(78.24 \text{ kJ/kg}) &= \dot{Q}_{\text{out}} + (4.521 \text{ kg/min})(27.45 \text{ kJ/kg}) + (0.07196 \text{ kg/min})(83.91 \text{ kJ/kg}) \\ \dot{Q}_{\text{out}} &= 223.6 \text{ kJ/min} = \mathbf{3.727 \text{ kW}} \end{aligned}$$

The properties of the R-134a at the inlet and exit of the cooling section are

$$\left. \begin{array}{l} P_{R1} = 350 \text{ kPa} \\ x_{R1} = 0.20 \end{array} \right\} h_{R1} = 97.56 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{R2} = 350 \text{ kPa} \\ x_{R2} = 1.0 \end{array} \right\} h_{R2} = 253.34 \text{ kJ/kg}$$

Noting that the rate of heat lost from the air is received by the refrigerant, the mass flow rate of the refrigerant is determined from

$$\dot{m}_R h_{R1} + \dot{Q}_{in} = \dot{m}_R h_{R2}$$

$$\dot{m}_R = \frac{\dot{Q}_{in}}{h_{R2} - h_{R1}} = \frac{223.6 \text{ kJ/min}}{(253.34 - 97.56) \text{ kJ/kg}} = \mathbf{1.435 \text{ kg/min}}$$

**14-149** An uninsulated tank contains moist air at a specified state. Water is sprayed into the tank until the relative humidity in the tank reaches a certain value. The amount of water supplied to the tank, the final pressure in the tank, and the heat transfer during the process are to be determined.

**Assumptions** 1 Dry air and water vapor are ideal gases. 2 The kinetic and potential energy changes are negligible.

**Analysis** The initial state of the moist air is completely specified. The properties of the air at the inlet state may be determined from the psychrometric chart (Figure A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 49.16 \text{ kJ/kg dry air}, \quad \omega_1 = 0.005433 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.6863 \text{ m}^3 / \text{kg dry air}$$

The initial mass in the tank is

$$m_a = \frac{\nu_1}{\nu_1} = \frac{0.5 \text{ m}^3}{0.6863 \text{ m}^3} = 0.7285 \text{ kg}$$

The partial pressure of dry air in the tank is

$$P_{a2} = \frac{m_a R_a T_2}{\nu} = \frac{(0.7285 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(35 + 273 \text{ K})}{(0.5 \text{ m}^3)} = 128.8 \text{ kPa}$$

Then, the pressure of moist air in the tank is determined from

$$P_2 = P_{a2} \left( 1 + \frac{\omega_2}{0.622} \right) = (128.8 \text{ kPa}) \left( 1 + \frac{\omega_2}{0.622} \right)$$

We cannot fix the final state explicitly by a hand-solution. However, using EES which has built-in functions for moist air properties, the final state properties are determined to be

$$P_2 = \mathbf{133.87 \text{ kPa}} \quad \omega_2 = 0.02446 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = 97.97 \text{ kJ/kg dry air} \quad \nu_2 = 0.6867 \text{ m}^3 / \text{kg dry air}$$

The partial pressures at the initial and final states are

$$P_{v1} = \phi_1 P_{\text{sat}@35^\circ\text{C}} = 0.20(5.6291 \text{ kPa}) = 1.126 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 130 - 1.126 = 128.87 \text{ kPa}$$

$$P_{v2} = P_2 - P_{a2} = 133.87 - 128.81 = 5.07 \text{ kPa}$$

The specific volume of water at 35°C is

$$\nu_{w1} = \nu_{w2} = \nu_{g@35^\circ\text{C}} = 25.205 \text{ m}^3/\text{kg}$$

The internal energies per unit mass of dry air in the tank are

$$u_1 = h_1 - P_{a1}\nu_1 - \omega_1 P_{v1}\nu_{w1} = 49.16 - 128.87 \times 0.6863 - 0.005433 \times 1.126 \times 25.205 = -39.44 \text{ kJ/kg}$$

$$u_2 = h_2 - P_{a2}\nu_2 - \omega_2 P_{v2}\nu_{w2} = 97.97 - 128.81 \times 0.6867 - 0.02446 \times 5.07 \times 25.205 = 6.396 \text{ kJ/kg}$$

The enthalpy of water entering the tank from the supply line is

$$h_{w1} = h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg}$$

The internal energy of water vapor at the final state is

$$u_{w2} = u_{g@35^\circ\text{C}} = 2422.7 \text{ kJ/kg}$$

The amount of water supplied to the tank is

$$m_w = m_a(\omega_2 - \omega_1) = (0.7285 \text{ kg})(0.02446 - 0.005433) = \mathbf{0.01386 \text{ kg}}$$

An energy balance on the system gives

$$E_{\text{in}} = \Delta E_{\text{tank}}$$

$$Q_{\text{in}} + m_w h_{w1} = m_a(u_2 - u_1) + m_w u_{w2}$$

$$Q_{\text{in}} + (0.01386 \text{ kg})(209.34 \text{ kJ/kg}) = (0.7285 \text{ kg})[6.396 - (-39.44) \text{ kJ/kg}] + (0.01386 \text{ kg})(2422.7 \text{ kJ/kg})$$

$$\dot{Q}_{\text{in}} = \mathbf{64.1 \text{ kJ}}$$

## Fundamentals of Engineering (FE) Exam Problems

**14-150** A room is filled with saturated moist air at 25°C and a total pressure of 100 kPa. If the mass of dry air in the room is 100 kg, the mass of water vapor is

- (a) 0.52 kg                      (b) 1.97 kg                      (c) 2.96 kg                      (d) 2.04 kg                      (e) 3.17 kg

*Answer* (d) 2.04 kg

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=25 "C"
P=100 "kPa"
m_air=100 "kg"
RH=1
P_g=PRESSURE(Steam_IAPWS,T=T1,x=0)
RH=P_v/P_g
P_air=P-P_v
w=0.622*P_v/(P-P_v)
w=m_v/m_air
```

"Some Wrong Solutions with Common Mistakes:"

W1\_vmass=m\_air\*w1; w1=0.622\*P\_v/P "Using P instead of P-Pv in w relation"

W2\_vmass=m\_air "Taking m\_vapor = m\_air"

**14-155** On the psychrometric chart, a cooling and dehumidification process appears as a line that is

- (a) horizontal to the left,  
 (b) vertical downward,  
 (c) diagonal upwards to the right (NE direction)  
 (d) diagonal upwards to the left (NW direction)  
 (e) diagonal downwards to the left (SW direction)

*Answer* (e) diagonal downwards to the left (SW direction)

**14-156** On the psychrometric chart, a heating and humidification process appears as a line that is

- (a) horizontal to the right,  
 (b) vertical upward,  
 (c) diagonal upwards to the right (NE direction)  
 (d) diagonal upwards to the left (NW direction)  
 (e) diagonal downwards to the right (SE direction)

*Answer* (c) diagonal upwards to the right (NE direction)

**14-157** An air stream at a specified temperature and relative humidity undergoes evaporative cooling by spraying water into it at about the same temperature. The lowest temperature the air stream can be cooled to is

- (a) the dry bulb temperature at the given state
- (b) the wet bulb temperature at the given state
- (c) the dew point temperature at the given state
- (d) the saturation temperature corresponding to the humidity ratio at the given state
- (e) the triple point temperature of water

*Answer* (a) the dry bulb temperature at the given state

**14-158** Air is cooled and dehumidified as it flows over the coils of a refrigeration system at 85 kPa from 30°C and a humidity ratio of 0.023 kg/kg dry air to 15°C and a humidity ratio of 0.015 kg/kg dry air. If the mass flow rate of dry air is 0.7 kg/s, the rate of heat removal from the air is

- (a) 5 kJ/s
- (b) 10 kJ/s
- (c) 15 kJ/s
- (d) 20 kJ/s
- (e) 25 kJ/s

*Answer* (e) 25 kJ/s

#### 14-160 ... 14-164 Design and Essay Problems

## Chapter 15

# CHEMICAL REACTIONS

### Fuels and Combustion

**15-1C** Gasoline is  $C_8H_{18}$ , diesel fuel is  $C_{12}H_{26}$ , and natural gas is  $CH_4$ .

**15-2C** Nitrogen, in general, does not react with other chemical species during a combustion process but its presence affects the outcome of the process because nitrogen absorbs a large proportion of the heat released during the chemical process.

**15-3C** Moisture, in general, does not react chemically with any of the species present in the combustion chamber, but it absorbs some of the energy released during combustion, and it raises the dew point temperature of the combustion gases.

**15-4C** The dew-point temperature of the product gases is the temperature at which the water vapor in the product gases starts to condense as the gases are cooled at constant pressure. It is the saturation temperature corresponding to the vapor pressure of the product gases.

**15-5C** The number of atoms are preserved during a chemical reaction, but the total mole numbers are not.

**15-6C** Air-fuel ratio is the ratio of the mass of air to the mass of fuel during a combustion process. Fuel-air ratio is the inverse of the air-fuel ratio.

**15-7C** No. Because the molar mass of the fuel and the molar mass of the air, in general, are different.

**15-8** Sulfur is burned with oxygen to form sulfur dioxide. The minimum mass of oxygen required and the mass of sulfur dioxide in the products are to be determined when 1 kg of sulfur is burned.

**Properties** The molar masses of sulfur and oxygen are 32.06 kg/kmol and 32.00 kg/kmol, respectively (Table A-1).

**Analysis** The chemical reaction is given by

Hence, 1 kmol of oxygen is required to burn 1 kmol of sulfur which produces 1 kmol of sulfur dioxide whose molecular weight is

$$M_{\text{SO}_2} = M_{\text{S}} + M_{\text{O}_2} = 32.06 + 32.00 = 64.06 \text{ kg/kmol}$$

Then,

$$\frac{m_{\text{O}_2}}{m_{\text{S}}} = \frac{N_{\text{O}_2} M_{\text{O}_2}}{N_{\text{S}} M_{\text{S}}} = \frac{(1 \text{ kmol})(32 \text{ kg/kmol})}{(1 \text{ kmol})(32.06 \text{ kg/kmol})} = \mathbf{0.998 \text{ kg O}_2/\text{kg S}}$$

and

$$\frac{m_{\text{SO}_2}}{m_{\text{S}}} = \frac{N_{\text{SO}_2} M_{\text{SO}_2}}{N_{\text{S}} M_{\text{S}}} = \frac{(1 \text{ kmol})(64.06 \text{ kg/kmol})}{(1 \text{ kmol})(32.06 \text{ kg/kmol})} = \mathbf{1.998 \text{ kg SO}_2/\text{kg S}}$$

**15-9E** Methane is burned with diatomic oxygen. The mass of water vapor in the products is to be determined when 1 lbm of methane is burned.

**Properties** The molar masses of CH<sub>4</sub>, O<sub>2</sub>, CO<sub>2</sub>, and H<sub>2</sub>O are 16, 32, 44, and 18 lbm/lbmol, respectively (Table A-1E).

**Analysis** The chemical reaction is given by

Hence, for each lbmol of methane burned, 2 lbmol of water vapor are formed. Then,

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{CH}_4}} = \frac{N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}}}{N_{\text{CH}_4} M_{\text{CH}_4}} = \frac{(2 \text{ lbmol})(18 \text{ lbm/lbmol})}{(1 \text{ lbmol})(16 \text{ lbm/lbmol})} = \mathbf{2.25 \text{ lbm H}_2\text{O}/\text{lbm CH}_4}$$

### Theoretical and Actual Combustion Processes

**15-10C** The causes of incomplete combustion are insufficient time, insufficient oxygen, insufficient mixing, and dissociation.

**15-11C** CO. Because oxygen is more strongly attracted to hydrogen than it is to carbon, and hydrogen is usually burned to completion even when there is a deficiency of oxygen.

**15-12C** It represent the amount of air that contains the exact amount of oxygen needed for complete combustion.

**15-13C** No. The theoretical combustion is also complete, but the products of theoretical combustion does not contain any uncombined oxygen.

**15-14C** Case (b).

**15-15** Propane is burned with theoretical amount of air. The mass fraction of carbon dioxide and the mole and mass fractions of the water vapor in the products are to be determined.

**Properties** The molar masses of  $C_3H_8$ ,  $O_2$ ,  $N_2$ ,  $CO_2$ , and  $H_2O$  are 44, 32, 28, 44, and 18 kg/kmol, respectively (Table A-1).

**Analysis** (a) The reaction in terms of undetermined coefficients is

Balancing the carbon in this reaction gives

$$y = 3$$

and the hydrogen balance gives

$$2z = 8 \longrightarrow z = 4$$

The oxygen balance produces

$$2x = 2y + z \longrightarrow x = y + z / 2 = 3 + 4 / 2 = 5$$

A balance of the nitrogen in this reaction gives

$$2 \times 3.76x = 2p \longrightarrow p = 3.76x = 3.76 \times 5 = 18.8$$

In balanced form, the reaction is

The mass fraction of carbon dioxide is determined from

$$\begin{aligned} mf_{CO_2} &= \frac{m_{CO_2}}{m_{products}} = \frac{N_{CO_2} M_{CO_2}}{N_{CO_2} M_{CO_2} + N_{H_2O} M_{H_2O} + N_{N_2} M_{N_2}} \\ &= \frac{(3 \text{ kmol})(44 \text{ kg/kmol})}{(3 \text{ kmol})(44 \text{ kg/kmol}) + (4 \text{ kmol})(18 \text{ kg/kmol}) + (18.8 \text{ kmol})(28 \text{ kg/kmol})} \\ &= \frac{132 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.181} \end{aligned}$$

(b) The mole and mass fractions of water vapor are

$$y_{H_2O} = \frac{N_{H_2O}}{N_{products}} = \frac{N_{H_2O}}{N_{CO_2} + N_{H_2O} + N_{N_2}} = \frac{4 \text{ kmol}}{3 \text{ kmol} + 4 \text{ kmol} + 18.8 \text{ kmol}} = \frac{4 \text{ kmol}}{25.8 \text{ kmol}} = \mathbf{0.155}$$

$$\begin{aligned} mf_{H_2O} &= \frac{m_{H_2O}}{m_{products}} = \frac{N_{H_2O} M_{H_2O}}{N_{CO_2} M_{CO_2} + N_{H_2O} M_{H_2O} + N_{N_2} M_{N_2}} \\ &= \frac{(4 \text{ kmol})(18 \text{ kg/kmol})}{(3 \text{ kmol})(44 \text{ kg/kmol}) + (4 \text{ kmol})(18 \text{ kg/kmol}) + (18.8 \text{ kmol})(28 \text{ kg/kmol})} \\ &= \frac{72 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.0986} \end{aligned}$$

**15-16** Methane is burned with air. The mass flow rates at the two inlets are to be determined.

**Properties** The molar masses of  $\text{CH}_4$ ,  $\text{O}_2$ ,  $\text{N}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$  are 16, 32, 28, 44, and 18 kg/kmol, respectively (Table A-1).

**Analysis** The stoichiometric combustion equation of  $\text{CH}_4$  is

$$\text{O}_2 \text{ balance:} \quad a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

The masses of the reactants are

$$m_{\text{CH}_4} = N_{\text{CH}_4} M_{\text{CH}_4} = (1 \text{ kmol})(16 \text{ kg/kmol}) = 16 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (2 \text{ kmol})(32 \text{ kg/kmol}) = 64 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (2 \times 3.76 \text{ kmol})(28 \text{ kg/kmol}) = 211 \text{ kg}$$

The total mass is

$$m_{\text{total}} = m_{\text{CH}_4} + m_{\text{O}_2} + m_{\text{N}_2} = 16 + 64 + 211 = 291 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{m_{\text{total}}} = \frac{16 \text{ kg}}{291 \text{ kg}} = 0.05498$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{64 \text{ kg}}{291 \text{ kg}} = 0.2199$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{211 \text{ kg}}{291 \text{ kg}} = 0.7251$$

For a mixture flow of 0.01 kg/s, the mass flow rates of the reactants are

$$\dot{m}_{\text{CH}_4} = \text{mf}_{\text{CH}_4} \dot{m} = (0.05498)(0.01 \text{ kg/s}) = \mathbf{0.0005498 \text{ kg/s}}$$

$$\dot{m}_{\text{air}} = \dot{m} - \dot{m}_{\text{CH}_4} = 0.01 - 0.0005498 = \mathbf{0.009450 \text{ kg/s}}$$

**15-17** n-Octane is burned with stoichiometric amount of oxygen. The mass fractions of each of the products and the mass of water in the products per unit mass of fuel burned are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ , and  $\text{O}_2$  are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation in this case is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (8 \text{ kmol})(44 \text{ kg/kmol}) = 352 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (9 \text{ kmol})(18 \text{ kg/kmol}) = 162 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} = 352 + 162 = 514 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{352 \text{ kg}}{514 \text{ kg}} = \mathbf{0.6848}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{162 \text{ kg}}{514 \text{ kg}} = \mathbf{0.3152}$$

The mass of water in the products per unit mass of fuel burned is determined from

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_8\text{H}_{18}}} = \frac{(9 \times 18) \text{ kg}}{(1 \times 114) \text{ kg}} = \mathbf{1.42 \text{ kg H}_2\text{O/kg C}_8\text{H}_{18}}$$

**15-18** Acetylene is burned with 10 percent excess oxygen. The mass fractions of each of the products and the mass of oxygen used per unit mass of fuel burned are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{O}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ , and  $\text{O}_2$  are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

**Analysis** The stoichiometric combustion equation is

The combustion equation with 10% excess oxygen is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (2 \text{ kmol})(44 \text{ kg/kmol}) = 88 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (1 \text{ kmol})(18 \text{ kg/kmol}) = 18 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (0.25 \text{ kmol})(32 \text{ kg/kmol}) = 8 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} + m_{\text{O}_2} = 88 + 18 + 8 = 114 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{88 \text{ kg}}{114 \text{ kg}} = \mathbf{0.7719}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{18 \text{ kg}}{114 \text{ kg}} = \mathbf{0.1579}$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{8 \text{ kg}}{114 \text{ kg}} = \mathbf{0.0702}$$

The mass of oxygen per unit mass of fuel burned is determined from

$$\frac{m_{\text{O}_2}}{m_{\text{C}_2\text{H}_2}} = \frac{(2.75 \times 32) \text{ kg}}{(1 \times 26) \text{ kg}} = \mathbf{3.385 \text{ kg O}_2/\text{kg C}_2\text{H}_2}$$

**15-19** Coal whose mass percentages are specified is burned with 50 percent excess air. The fuel-air ratio is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ ,  $\text{N}_2$ , and  $\text{O}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ , S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$\text{mf}_C = \frac{m_C}{m_{\text{total}}} = \frac{79.61 \text{ kg}}{(100 - 8.62) \text{ kg}} = \frac{79.61 \text{ kg}}{91.38 \text{ kg}} = 0.8712$$

$$\text{mf}_{\text{H}_2} = \frac{m_{\text{H}_2}}{m_{\text{total}}} = \frac{4.66 \text{ kg}}{91.38 \text{ kg}} = 0.05100$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{4.76 \text{ kg}}{91.38 \text{ kg}} = 0.05209$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1.83 \text{ kg}}{91.38 \text{ kg}} = 0.02003$$

$$\text{mf}_S = \frac{m_S}{m_{\text{total}}} = \frac{0.52 \text{ kg}}{91.38 \text{ kg}} = 0.00569$$

|                    |
|--------------------|
| 79.61% C           |
| 4.66% $\text{H}_2$ |
| 4.76% $\text{O}_2$ |
| 1.83% $\text{N}_2$ |
| 0.52% S            |
| 8.62% ash          |
| (by mass)          |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_C = \frac{m_C}{M_C} = \frac{87.12 \text{ kg}}{12 \text{ kg/kmol}} = 7.26 \text{ kmol}$$

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{5.10 \text{ kg}}{2 \text{ kg/kmol}} = 2.55 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{5.209 \text{ kg}}{32 \text{ kg/kmol}} = 0.1628 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{2.003 \text{ kg}}{28 \text{ kg/kmol}} = 0.07154 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.569 \text{ kg}}{32 \text{ kg/kmol}} = 0.01778 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 7.26 + 2.55 + 0.1628 + 0.07154 + 0.01778 = 10.06 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{7.26 \text{ kmol}}{10.06 \text{ kmol}} = 0.7215$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_m} = \frac{2.55 \text{ kmol}}{10.06 \text{ kmol}} = 0.2535$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.1628 \text{ kmol}}{10.06 \text{ kmol}} = 0.01618$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.07154 \text{ kmol}}{10.06 \text{ kmol}} = 0.00711$$

$$y_S = \frac{N_S}{N_m} = \frac{0.01778 \text{ kmol}}{10.06 \text{ kmol}} = 0.00177$$

Then, the combustion equation in this case may be written as

According to the species balances,

$$\text{C balance: } x = 0.7215$$

$$\text{H}_2 \text{ balance: } y = 0.2535$$

$$\text{S balance: } z = 0.00177$$

$$\text{O}_2 \text{ balance:}$$

$$0.01618 + 1.5a_{\text{th}} = x + 0.5y + z + 0.5a_{\text{th}}$$

$$1.5a_{\text{th}} - 0.5a_{\text{th}} = 0.7215 + 0.5(0.2535) + 0.00177 - 0.01617 \longrightarrow a_{\text{th}} = 0.8339$$

$$\text{N}_2 \text{ balance: } 0.00711 + 1.5 \times 3.76a_{\text{th}} = k \longrightarrow k = 0.00711 + 1.5 \times 3.76 \times 0.8339 = 4.710$$

Substituting,

The fuel-air mass ratio is then

$$\text{FA} = \frac{m_{\text{fuel}}}{m_{\text{air}}} = \frac{(0.7215 \times 12 + 0.2535 \times 2 + 0.01617 \times 32 + 0.00711 \times 28 + 0.00177 \times 32) \text{ kg}}{(1.2509 \times 4.76 \times 29) \text{ kg}} \\ = \frac{9.938 \text{ kg}}{172.5 \text{ kg}} = \mathbf{0.0576 \text{ kg fuel/kg air}}$$

**15-20** Propane is burned with 75 percent excess air during a combustion process. The AF ratio is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. We have automatically accounted for the 75% excess air by using the factor  $1.75a_{\text{th}}$  instead of  $a_{\text{th}}$  for air. The stoichiometric amount of oxygen ( $a_{\text{th}}\text{O}_2$ ) will be used to oxidize the fuel, and the remaining excess amount ( $0.75a_{\text{th}}\text{O}_2$ ) will appear in the products as free oxygen. The coefficient  $a_{\text{th}}$  is determined from the  $\text{O}_2$  balance,

$$\text{O}_2 \text{ balance:} \quad 1.75a_{\text{th}} = 3 + 2 + 0.75a_{\text{th}} \quad \longrightarrow \quad a_{\text{th}} = 5$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(8.75 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{27.5 \text{ kg air/kg fuel}}$$

**15-21** Acetylene is burned with the stoichiometric amount of air during a combustion process. The AF ratio is to be determined on a mass and on a mole basis.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** This is a theoretical combustion process since  $\text{C}_2\text{H}_2$  is burned completely with stoichiometric amount of air. The stoichiometric combustion equation of  $\text{C}_2\text{H}_2$  is

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 2 + 0.5 \longrightarrow a_{\text{th}} = 2.5$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(2.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(2 \text{ kmol})(12 \text{ kg/kmol}) + (1 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{13.3 \text{ kg air/kg fuel}}$$

On a mole basis, the air-fuel ratio is expressed as the ratio of the mole numbers of the air to the mole numbers of the fuel,

$$\text{AF}_{\text{mole basis}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{(2.5 \times 4.76) \text{ kmol}}{1 \text{ kmol fuel}} = \mathbf{11.9 \text{ kmol air/kmol fuel}}$$

**15-22E** Ethylene is burned with 200 percent theoretical air during a combustion process. The AF ratio and the dew-point temperature of the products are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only. 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 lbm/lbmol, 2 lbm/lbmol, and 29 lbm/lbmol, respectively (Table A-1E).

**Analysis** (a) The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance:} \quad 2a_{\text{th}} = 2 + 1 + a_{\text{th}} \longrightarrow a_{\text{th}} = 3$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(6 \times 4.76 \text{ lbmol})(29 \text{ lbm/lbmol})}{(2 \text{ lbmol})(12 \text{ lbm/lbmol}) + (2 \text{ lbmol})(2 \text{ lbm/lbmol})} = \mathbf{29.6 \text{ lbm air/lbm fuel}}$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left( \frac{2 \text{ lbmol}}{29.56 \text{ lbmol}} \right) (14.5 \text{ psia}) = 0.981 \text{ psia}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@0.981 \text{ psia}} = \mathbf{101^\circ\text{F}}$$

**15-23** Propylene is burned with 50 percent excess air during a combustion process. The AF ratio and the temperature at which the water vapor in the products will start condensing are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only. 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } 1.5a_{\text{th}} = 3 + 1.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 4.5$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(6.75 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (3 \text{ kmol})(2 \text{ kg/kmol})} = 22.2 \text{ kg air/kg fuel}$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left( \frac{3 \text{ kmol}}{33.63 \text{ kmol}} \right) (105 \text{ kPa}) = 9.367 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@9.367 \text{ kPa}} = 44.5^\circ\text{C}$$

**15-24** Butane  $C_4H_{10}$  is burned with 200 percent theoretical air. The kmol of water that needs to be sprayed into the combustion chamber per kmol of fuel is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $CO_2$ ,  $H_2O$ ,  $O_2$ , and  $N_2$  only.

**Properties** The molar masses of C,  $H_2$ ,  $O_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The reaction equation for 200% theoretical air without the additional water is

where  $a_{th}$  is the stoichiometric coefficient for air. We have automatically accounted for the 100% excess air by using the factor  $2a_{th}$  instead of  $a_{th}$  for air. The coefficient  $a_{th}$  and other coefficients are to be determined from the mass balances

Carbon balance:  $B = 4$

Hydrogen balance:  $2D = 10 \longrightarrow D = 5$

Oxygen balance:  $2 \times 2a_{th} = 2B + D + 2E$

$$a_{th} = E$$

Nitrogen balance:  $2a_{th} \times 3.76 = F$

Solving the above equations, we find the coefficients ( $E = 6.5$ ,  $F = 48.88$ , and  $a_{th} = 6.5$ ) and write the balanced reaction equation as

With the additional water sprayed into the combustion chamber, the balanced reaction equation is

The partial pressure of water in the saturated product mixture at the dew point is

$$P_{v,prod} = P_{sat@60^\circ C} = 19.95 \text{ kPa}$$

The vapor mole fraction is

$$y_v = \frac{P_{v,prod}}{P_{prod}} = \frac{19.95 \text{ kPa}}{100 \text{ kPa}} = 0.1995$$

The amount of water that needs to be sprayed into the combustion chamber can be determined from

$$y_v = \frac{N_{water}}{N_{total,product}} \longrightarrow 0.1995 = \frac{5 + N_v}{4 + 5 + N_v + 6.5 + 48.88} \longrightarrow N_v = \mathbf{9.796 \text{ kmol}}$$

**15-25** A fuel mixture of 20% by mass methane,  $\text{CH}_4$ , and 80% by mass ethanol,  $\text{C}_2\text{H}_6\text{O}$ , is burned completely with theoretical air. The required flow rate of air is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. The coefficient  $a_{\text{th}}$  and other coefficients are to be determined from the mass balances

$$\text{Carbon balance:} \quad x + 2y = B$$

$$\text{Hydrogen balance:} \quad 4x + 6y = 2D$$

$$\text{Oxygen balance:} \quad 2a_{\text{th}} + y = 2B + D$$

$$\text{Nitrogen balance:} \quad 3.76a_{\text{th}} = F$$

Solving the above equations, we find the coefficients as

$$x = 0.4182 \quad B = 1.582$$

$$y = 0.5818 \quad D = 2.582$$

$$a_{\text{th}} = 2.582 \quad F = 9.708$$

Then, we write the balanced reaction equation as

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\begin{aligned} \text{AF} &= \frac{m_{\text{air}}}{m_{\text{fuel}}} \\ &= \frac{(2.582 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(0.4182 \text{ kmol})(12 + 4 \times 1) \text{ kg/kmol} + (0.5818 \text{ kmol})(2 \times 12 + 6 \times 1 + 16) \text{ kg/kmol}} \\ &= 10.64 \text{ kg air/kg fuel} \end{aligned}$$

Then, the required flow rate of air becomes

$$\dot{m}_{\text{air}} = \text{AF} \dot{m}_{\text{fuel}} = (10.64)(31 \text{ kg/s}) = \mathbf{330 \text{ kg/s}}$$

**15-26** Octane is burned with 250 percent theoretical air during a combustion process. The AF ratio and the dew-point temperature of the products are to be determined.

**Assumptions** **1** Combustion is complete. **2** The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only. **3** Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air.

It is determined from

$$\text{O}_2 \text{ balance: } 2.5a_{\text{th}} = 8 + 4.5 + 1.5a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Substituting,

Thus,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(31.25 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(8 \text{ kmol})(12 \text{ kg/kmol}) + (9 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{37.8 \text{ kg air/kg fuel}}$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left( \frac{9 \text{ kmol}}{153.25 \text{ kmol}} \right) (101.325 \text{ kPa}) = 5.951 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@5.951 \text{ kPa}} = \mathbf{36.0^\circ\text{C}}$$

**15-27** Gasoline is burned steadily with air in a jet engine. The AF ratio is given. The percentage of excess air used is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The theoretical combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 8 + 4.5 \longrightarrow a_{\text{th}} = 12.5$$

The air-fuel ratio for the theoretical reaction is determined by taking the ratio of the mass of the air to the mass of the fuel for,

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(8 \text{ kmol})(12 \text{ kg/kmol}) + (9 \text{ kmol})(2 \text{ kg/kmol})} = 15.14 \text{ kg air/kg fuel}$$

Then the percent theoretical air used can be determined from

$$\text{Percent theoretical air} = \frac{\text{AF}_{\text{act}}}{\text{AF}_{\text{th}}} = \frac{18 \text{ kg air/kg fuel}}{15.14 \text{ kg air/kg fuel}} = \mathbf{119\%}$$

**15-28** n-butane is burned with stoichiometric amount of air. The mass fraction of each product, the mass of  $\text{CO}_2$  and air per unit mass of fuel burned are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The reaction equation for 100% theoretical air is

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. The coefficient  $a_{\text{th}}$  and other coefficients are to be determined from the mass balances

Carbon balance:  $B = 4$

Hydrogen balance:  $2D = 10 \longrightarrow D = 5$

Oxygen balance:  $2a_{\text{th}} = 2B + D \longrightarrow a_{\text{th}} = 0.5(2 \times 4 + 5) = 6.5$

Nitrogen balance:  $a_{\text{th}} \times 3.76 = E \longrightarrow E = 6.5 \times 3.76 = 24.44$

Substituting, the balanced reaction equation is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (4 \text{ kmol})(44 \text{ kg/kmol}) = 176 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (5 \text{ kmol})(18 \text{ kg/kmol}) = 90 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (24.44 \text{ kmol})(28 \text{ kg/kmol}) = 684 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} = 176 + 90 + 684 = 950 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{176 \text{ kg}}{950 \text{ kg}} = \mathbf{0.1853}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{90 \text{ kg}}{950 \text{ kg}} = \mathbf{0.0947}$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{684 \text{ kg}}{950 \text{ kg}} = \mathbf{0.720}$$

The mass of carbon dioxide per unit mass of fuel burned is

$$\frac{m_{\text{CO}_2}}{m_{\text{C}_4\text{H}_{10}}} = \frac{(4 \times 44) \text{ kg}}{(1 \times 58) \text{ kg}} = \mathbf{3.034 \text{ kg CO}_2/\text{kg C}_4\text{H}_{10}}$$

The mass of air required per unit mass of fuel burned is

$$\frac{m_{\text{air}}}{m_{\text{C}_4\text{H}_{10}}} = \frac{(6.5 \times 4.76 \times 29) \text{ kg}}{(1 \times 58) \text{ kg}} = \mathbf{15.47 \text{ kg air/kg C}_4\text{H}_{10}}$$

**15-29** Coal whose mass percentages are specified is burned with stoichiometric amount of air. The mole fractions of the products, the apparent molecular weight of the product gas, and the air-fuel ratio are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ , and  $\text{N}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ , S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$\text{mf}_\text{C} = \frac{m_\text{C}}{m_\text{total}} = \frac{84.36 \text{ kg}}{(100 - 7.83) \text{ kg}} = \frac{84.36 \text{ kg}}{92.17 \text{ kg}} = 0.9153$$

$$\text{mf}_\text{H}_2 = \frac{m_\text{H}_2}{m_\text{total}} = \frac{1.89 \text{ kg}}{92.17 \text{ kg}} = 0.02051$$

$$\text{mf}_\text{O}_2 = \frac{m_\text{O}_2}{m_\text{total}} = \frac{4.40 \text{ kg}}{92.17 \text{ kg}} = 0.04774$$

$$\text{mf}_\text{N}_2 = \frac{m_\text{N}_2}{m_\text{total}} = \frac{0.63 \text{ kg}}{92.17 \text{ kg}} = 0.006835$$

$$\text{mf}_\text{S} = \frac{m_\text{S}}{m_\text{total}} = \frac{0.89 \text{ kg}}{92.17 \text{ kg}} = 0.009656$$

|                    |
|--------------------|
| 84.36% C           |
| 1.89% $\text{H}_2$ |
| 4.40% $\text{O}_2$ |
| 0.63% $\text{N}_2$ |
| 0.89% S            |
| 7.83% ash          |
| (by mass)          |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_\text{C} = \frac{m_\text{C}}{M_\text{C}} = \frac{91.53 \text{ kg}}{12 \text{ kg/kmol}} = 7.628 \text{ kmol}$$

$$N_\text{H}_2 = \frac{m_\text{H}_2}{M_\text{H}_2} = \frac{2.051 \text{ kg}}{2 \text{ kg/kmol}} = 1.026 \text{ kmol}$$

$$N_\text{O}_2 = \frac{m_\text{O}_2}{M_\text{O}_2} = \frac{4.774 \text{ kg}}{32 \text{ kg/kmol}} = 0.1492 \text{ kmol}$$

$$N_\text{N}_2 = \frac{m_\text{N}_2}{M_\text{N}_2} = \frac{0.6835 \text{ kg}}{28 \text{ kg/kmol}} = 0.02441 \text{ kmol}$$

$$N_\text{S} = \frac{m_\text{S}}{M_\text{S}} = \frac{0.9656 \text{ kg}}{32 \text{ kg/kmol}} = 0.03018 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 7.628 + 1.026 + 0.1492 + 0.02441 + 0.03018 = 8.858 \text{ kmol}$$

$$y_\text{C} = \frac{N_\text{C}}{N_m} = \frac{7.628 \text{ kmol}}{8.858 \text{ kmol}} = 0.8611$$

$$y_\text{H}_2 = \frac{N_\text{H}_2}{N_m} = \frac{1.026 \text{ kmol}}{8.858 \text{ kmol}} = 0.1158$$

$$y_\text{O}_2 = \frac{N_\text{O}_2}{N_m} = \frac{0.1492 \text{ kmol}}{8.858 \text{ kmol}} = 0.01684$$

$$y_\text{N}_2 = \frac{N_\text{N}_2}{N_m} = \frac{0.02441 \text{ kmol}}{8.858 \text{ kmol}} = 0.002756$$

$$y_\text{S} = \frac{N_\text{S}}{N_m} = \frac{0.03018 \text{ kmol}}{8.858 \text{ kmol}} = 0.003407$$

Then, the combustion equation in this case may be written as

According to the species balances,

$$\text{C balance: } x = 0.8611$$

$$\text{H}_2 \text{ balance: } y = 0.1158$$

$$\text{S balance: } z = 0.003407$$

$$\text{O}_2 \text{ balance:}$$

$$0.01684 + a_{\text{th}} = x + 0.5y + z$$

$$a_{\text{th}} = 0.8611 + 0.5(0.1158) + 0.003407 - 0.01684 = 0.9056$$

$$\text{N}_2 \text{ balance: } k = 0.002756 + 3.76a_{\text{th}} = 0.002756 + 3.76 \times 0.9056 = 3.408$$

Substituting,

The mole fractions of the products are

$$N_m = 0.8611 + 0.1158 + 0.00341 + 3.408 = 4.388 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.8611 \text{ kmol}}{4.388 \text{ kmol}} = \mathbf{0.1962}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{0.1158 \text{ kmol}}{4.388 \text{ kmol}} = \mathbf{0.02639}$$

$$y_{\text{SO}_2} = \frac{N_{\text{SO}_2}}{N_m} = \frac{0.00341 \text{ kmol}}{4.388 \text{ kmol}} = \mathbf{0.00078}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{3.408 \text{ kmol}}{4.388 \text{ kmol}} = \mathbf{0.7767}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{(0.8611 \times 44 + 0.1158 \times 18 + 0.00341 \times 64 + 3.408 \times 28) \text{ kg}}{4.388 \text{ kmol}} = \mathbf{30.91 \text{ kg/kmol}}$$

The air-fuel mass ratio is then

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(0.9056 \times 4.76 \times 29) \text{ kg}}{(0.8611 \times 12 + 0.1158 \times 2 + 0.01684 \times 32 + 0.002756 \times 28 + 0.003408 \times 32) \text{ kg}} \\ = \frac{125.0 \text{ kg}}{11.29 \text{ kg}} = \mathbf{11.07 \text{ kg air/kg fuel}}$$

**15-30** Methyl alcohol is burned with stoichiometric amount of air. The mole fraction of each product, the apparent molar mass of the product gas, and the mass of water in the products per unit mass of fuel burned are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The balanced reaction equation for stoichiometric air is

The mole fractions of the products are

$$N_m = 1 + 2 + 5.64 = 8.64 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{1 \text{ kmol}}{8.64 \text{ kmol}} = \mathbf{0.1157}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{2 \text{ kmol}}{8.64 \text{ kmol}} = \mathbf{0.2315}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{5.64 \text{ kmol}}{8.64 \text{ kmol}} = \mathbf{0.6528}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{(1 \times 44 + 2 \times 18 + 5.64 \times 28) \text{ kg}}{8.64 \text{ kmol}} = \mathbf{27.54 \text{ kg/kmol}}$$

The mass of water in the products per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{CH}_3\text{OH}}} = \frac{(2 \times 18) \text{ kg}}{(1 \times 32) \text{ kg}} = \mathbf{1.125 \text{ kg H}_2\text{O/kg CH}_3\text{OH}}$$

**15-31** Coal whose mass percentages are specified is burned with stoichiometric amount of air. The combustion is incomplete. The mass fractions of the products, the apparent molecular weight of the product gas, and the air-fuel ratio are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ , and  $\text{N}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ , S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$\text{mf}_\text{C} = \frac{m_\text{C}}{m_\text{total}} = \frac{61.40 \text{ kg}}{(100 - 5.00) \text{ kg}} = \frac{61.40 \text{ kg}}{95.00 \text{ kg}} = 0.6463$$

$$\text{mf}_\text{H}_2 = \frac{m_\text{H}_2}{m_\text{total}} = \frac{5.79 \text{ kg}}{95.00 \text{ kg}} = 0.06095$$

$$\text{mf}_\text{O}_2 = \frac{m_\text{O}_2}{m_\text{total}} = \frac{25.31 \text{ kg}}{95.00 \text{ kg}} = 0.2664$$

$$\text{mf}_\text{N}_2 = \frac{m_\text{N}_2}{m_\text{total}} = \frac{1.09 \text{ kg}}{95.00 \text{ kg}} = 0.01147$$

$$\text{mf}_\text{S} = \frac{m_\text{S}}{m_\text{total}} = \frac{1.41 \text{ kg}}{95.00 \text{ kg}} = 0.01484$$

|                     |
|---------------------|
| 61.40% C            |
| 5.79% $\text{H}_2$  |
| 25.31% $\text{O}_2$ |
| 1.09% $\text{N}_2$  |
| 1.41% S             |
| 5.00% ash           |
| (by mass)           |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_\text{C} = \frac{m_\text{C}}{M_\text{C}} = \frac{61.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.117 \text{ kmol}$$

$$N_\text{H}_2 = \frac{m_\text{H}_2}{M_\text{H}_2} = \frac{5.79 \text{ kg}}{2 \text{ kg/kmol}} = 2.895 \text{ kmol}$$

$$N_\text{O}_2 = \frac{m_\text{O}_2}{M_\text{O}_2} = \frac{25.31 \text{ kg}}{32 \text{ kg/kmol}} = 0.791 \text{ kmol}$$

$$N_\text{N}_2 = \frac{m_\text{N}_2}{M_\text{N}_2} = \frac{1.09 \text{ kg}}{28 \text{ kg/kmol}} = 0.039 \text{ kmol}$$

$$N_\text{S} = \frac{m_\text{S}}{M_\text{S}} = \frac{1.41 \text{ kg}}{32 \text{ kg/kmol}} = 0.044 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 5.117 + 2.895 + 0.791 + 0.039 + 0.044 = 9.354 \text{ kmol}$$

$$y_\text{C} = \frac{N_\text{C}}{N_m} = \frac{5.117 \text{ kmol}}{9.354 \text{ kmol}} = 0.547$$

$$y_\text{H}_2 = \frac{N_\text{H}_2}{N_m} = \frac{2.895 \text{ kmol}}{9.354 \text{ kmol}} = 0.310$$

$$y_\text{O}_2 = \frac{N_\text{O}_2}{N_m} = \frac{0.791 \text{ kmol}}{9.354 \text{ kmol}} = 0.085$$

$$y_\text{N}_2 = \frac{N_\text{N}_2}{N_m} = \frac{0.039 \text{ kmol}}{9.354 \text{ kmol}} = 0.004$$

$$y_\text{S} = \frac{N_\text{S}}{N_m} = \frac{0.044 \text{ kmol}}{9.354 \text{ kmol}} = 0.005$$

Then, the combustion equation in this case may be written as

According to the species balances,

$$\text{C balance: } x = 0.5758$$

$$\text{H}_2 \text{ balance: } y = 0.3258$$

$$\text{S balance: } z = 0.00496$$

$$\text{O}_2 \text{ balance:}$$

$$0.0890 + a_{\text{th}} = 0.95x + 0.5 \times 0.05x + 0.5y + z$$

$$a_{\text{th}} = 0.95 \times 0.5758 + 0.5 \times 0.05 \times 0.5758 + 0.5 \times 0.3258 + 0.00496 - 0.0890 = 0.6403$$

$$\text{N}_2 \text{ balance: } k = 0.00438 + 3.76a_{\text{th}} = 0.00438 + 3.76 \times 0.6403 = 2.412$$

Substituting,

The mass fractions of the products are

$$m_{\text{total}} = 0.5470 \times 44 + 0.0288 \times 28 + 0.3258 \times 18 + 0.00496 \times 64 + 2.412 \times 28 = 98.6 \text{ kg}$$

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{(0.5470 \times 44) \text{ kg}}{98.6 \text{ kg}} = \mathbf{0.2441}$$

$$\text{mf}_{\text{CO}} = \frac{m_{\text{CO}}}{m_{\text{total}}} = \frac{(0.0288 \times 28) \text{ kg}}{98.6 \text{ kg}} = \mathbf{0.0082}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{(0.3258 \times 18) \text{ kg}}{98.6 \text{ kg}} = \mathbf{0.0595}$$

$$\text{mf}_{\text{SO}_2} = \frac{m_{\text{SO}_2}}{m_{\text{total}}} = \frac{(0.00496 \times 64) \text{ kg}}{98.6 \text{ kg}} = \mathbf{0.0032}$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{(2.412 \times 28) \text{ kg}}{98.6 \text{ kg}} = \mathbf{0.6849}$$

The total mole number of the products is

$$N_m = 0.5470 + 0.0288 + 0.3258 + 0.00496 + 2.712 = 3.319 \text{ kmol}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{98.6 \text{ kg}}{3.319 \text{ kmol}} = \mathbf{29.71 \text{ kg/kmol}}$$

The air-fuel mass ratio is then

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(0.6403 \times 4.76 \times 29) \text{ kg}}{(0.5758 \times 12 + 0.3258 \times 2 + 0.0890 \times 32 + 0.00438 \times 28 + 0.00496 \times 32) \text{ kg}} \\ = \frac{88.39 \text{ kg}}{10.69 \text{ kg}} \\ = \mathbf{8.27 \text{ kg air/kg fuel}}$$

**15-32** Propane is burned with 30 percent excess air. The mole fractions of each of the products, the mass of water in the products per unit mass of the fuel, and the air-fuel ratio are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ , and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. We have automatically accounted for the 30% excess air by using the factor  $1.3a_{\text{th}}$  instead of  $a_{\text{th}}$  for air. The stoichiometric amount of oxygen ( $a_{\text{th}}\text{O}_2$ ) will be used to oxidize the fuel, and the remaining excess amount ( $0.3a_{\text{th}}\text{O}_2$ ) will appear in the products as free oxygen. The coefficient  $a_{\text{th}}$  is determined from the  $\text{O}_2$  balance,

$$\text{O}_2 \text{ balance:} \quad 1.3a_{\text{th}} = 3 + 2 + 0.3a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

$$\text{Substituting,} \quad \text{C}_3\text{H}_8 + 6.5[\text{O}_2 + 3.76\text{N}_2] \longrightarrow 3\text{CO}_2 + 4\text{H}_2\text{O} + 1.5\text{O}_2 + 24.44\text{N}_2$$

The mole fractions of the products are

$$N_m = 3 + 4 + 1.5 + 24.44 = 32.94 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{3 \text{ kmol}}{32.94 \text{ kmol}} = \mathbf{0.0911}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{4 \text{ kmol}}{32.94 \text{ kmol}} = \mathbf{0.1214}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{1.5 \text{ kmol}}{32.94 \text{ kmol}} = \mathbf{0.0455}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{24.44 \text{ kmol}}{32.94 \text{ kmol}} = \mathbf{0.7420}$$

The mass of water in the products per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_3\text{H}_8}} = \frac{(4 \times 18) \text{ kg}}{(1 \times 44) \text{ kg}} = \mathbf{1.636 \text{ kg H}_2\text{O/kg C}_3\text{H}_8}$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(6.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{20.39 \text{ kg air/kg fuel}}$$

**15-33** The volumetric fractions of the constituents of a certain natural gas are given. The AF ratio is to be determined if this gas is burned with the stoichiometric amount of dry air.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ , and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.65 + 0.06 = x \longrightarrow x = 0.71$$

$$\text{H: } 0.65 \times 4 + 0.08 \times 2 = 2y \longrightarrow y = 1.38$$

$$\text{O}_2: 0.03 + 0.06 + a_{\text{th}} = x + y/2 \longrightarrow a_{\text{th}} = 1.31$$

$$\text{N}_2: 0.18 + 3.76a_{\text{th}} = z \longrightarrow z = 5.106$$

Thus,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.31 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 180.8 \text{ kg}$$

$$m_{\text{fuel}} = (0.65 \times 16 + 0.08 \times 2 + 0.18 \times 28 + 0.03 \times 32 + 0.06 \times 44) \text{ kg} = 19.2 \text{ kg}$$

and

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{180.8 \text{ kg}}{19.2 \text{ kg}} = \mathbf{9.42 \text{ kg air/kg fuel}}$$

**15-34** The composition of a certain natural gas is given. The gas is burned with stoichiometric amount of moist air. The AF ratio is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ , and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only  $\text{H}_2\text{O}$ ,  $\text{CO}_2$  and  $\text{N}_2$ , but no free  $\text{O}_2$ . The moisture in the air does not react with anything; it simply shows up as additional  $\text{H}_2\text{O}$  in the products. Therefore, we can simply balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C} : 0.65 + 0.06 = x \longrightarrow x = 0.71$$

$$\text{H} : 0.65 \times 4 + 0.08 \times 2 = 2y \longrightarrow y = 1.38$$

$$\text{O}_2 : 0.03 + 0.06 + a_{\text{th}} = x + y/2 \longrightarrow a_{\text{th}} = 1.31$$

$$\text{N}_2 : 0.18 + 3.76a_{\text{th}} = z \longrightarrow z = 5.106$$

Thus,

Next we determine the amount of moisture that accompanies  $4.76a_{\text{th}} = (4.76)(1.31) = 6.24$  kmol of dry air. The partial pressure of the moisture in the air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@25^\circ\text{C}} = (0.85)(3.1698 \text{ kPa}) = 2.694 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture in the air ( $N_{v,\text{in}}$ ) is determined to be

$$N_{v,\text{in}} = \left( \frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left( \frac{2.694 \text{ kPa}}{101.325 \text{ kPa}} \right) (6.24 + N_{v,\text{in}}) \longrightarrow N_{v,\text{air}} = 0.17 \text{ kmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.17 kmol of  $\text{H}_2\text{O}$  to both sides of the equation,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.31 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) + (0.17 \text{ kmol} \times 18 \text{ kg/kmol}) = 183.9 \text{ kg}$$

$$m_{\text{fuel}} = (0.65 \times 16 + 0.08 \times 2 + 0.18 \times 28 + 0.03 \times 32 + 0.06 \times 44) \text{ kg} = 19.2 \text{ kg}$$

and

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{183.9 \text{ kg}}{19.2 \text{ kg}} = \mathbf{9.58 \text{ kg air/kg fuel}}$$

**15-35** The composition of a gaseous fuel is given. It is burned with 130 percent theoretical air. The AF ratio and the fraction of water vapor that would condense if the product gases were cooled are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{N}_2$ , and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The fuel is burned completely with excess air, and thus the products will contain  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.60 = x \longrightarrow x = 0.60$$

$$\text{H: } 0.60 \times 4 + 0.30 \times 2 = 2y \longrightarrow y = 1.50$$

$$\text{O}_2: 1.3a_{\text{th}} = x + y/2 + 0.3a_{\text{th}} \longrightarrow a_{\text{th}} = 1.35$$

$$\text{N}_2: 0.10 + 3.76 \times 1.3a_{\text{th}} = z \longrightarrow z = 6.70$$

Thus,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.755 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 242.3 \text{ kg}$$

$$m_{\text{fuel}} = (0.6 \times 16 + 0.3 \times 2 + 0.1 \times 28) \text{ kg} = 13.0 \text{ kg}$$

and

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{242.3 \text{ kg}}{13.0 \text{ kg}} = \mathbf{18.6 \text{ kg air/kg fuel}}$$

(b) For each kmol of fuel burned,  $0.6 + 1.5 + 0.405 + 6.7 = 9.205$  kmol of products are formed, including 1.5 kmol of  $\text{H}_2\text{O}$ . Assuming that the dew-point temperature of the products is above  $20^\circ\text{C}$ , some of the water vapor will condense as the products are cooled to  $20^\circ\text{C}$ . If  $N_w$  kmol of  $\text{H}_2\text{O}$  condenses, there will be  $1.5 - N_w$  kmol of water vapor left in the products. The mole number of the products in the gas phase will also decrease to  $9.205 - N_w$  as a result. Treating the product gases (including the remaining water vapor) as ideal gases,  $N_w$  is determined by equating the mole fraction of the water vapor to its pressure fraction,

$$\frac{N_v}{N_{\text{prod, gas}}} = \frac{P_v}{P_{\text{prod}}} \longrightarrow \frac{1.5 - N_w}{9.205 - N_w} = \frac{2.3392 \text{ kPa}}{101.325 \text{ kPa}} \longrightarrow N_w = 1.32 \text{ kmol}$$

since  $P_v = P_{\text{sat @ } 20^\circ\text{C}} = 2.3392 \text{ kPa}$ . Thus the fraction of water vapor that condenses is  $1.32/1.5 = 0.88$  or **88%**.

**15-36 EES** Problem 15-35 is reconsidered. The effects of varying the percentages of CH<sub>4</sub>, H<sub>2</sub> and N<sub>2</sub> making up the fuel and the product gas temperature are to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

Let's modify this problem to include the fuels butane, ethane, methane, and propane in pull down menu. Adiabatic Combustion of fuel C<sub>n</sub>H<sub>m</sub> entering at T<sub>fuel</sub> with Stoichiometric Air at T<sub>air</sub>:

Reaction:  $aC_xH_y + bH_2 + cN_2 + (a*y/4 + a*x + b/2) (Theo\_air/100) (O_2 + 3.76 N_2)$   
 $\longleftrightarrow a*xCO_2 + ((a*y/2) + b) H_2O + (c + 3.76 (a*y/4 + a*x + b/2) (Theo\_air/100)) N_2 + (a*y/4 + a*x + b/2) (Theo\_air/100 - 1) O_2$

T<sub>prod</sub> is the product gas temperature.

Theo<sub>air</sub> is the % theoretical air. "

**15-37** Carbon is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** Considering 100 kmol of dry products, the combustion equation can be written as

The unknown coefficients  $x$  and  $a$  are determined from mass balances,

$$\text{N}_2 : 3.76a = 78.83 \longrightarrow a = 20.965$$

$$\text{C} : x = 10.06 + 0.42 \longrightarrow x = 10.48$$

$$(\text{Check O}_2 : a = 10.06 + 0.21 + 10.69 \longrightarrow 20.96 = 20.96)$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 10.48,

(a) The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(2.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(12 \text{ kg/kmol})} = \mathbf{23.0 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

Then,

$$\text{Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(2.0)(4.76) \text{ kmol}}{(1.0)(4.76) \text{ kmol}} = \mathbf{200\%}$$

**15-38** Methane is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** Considering 100 kmol of dry products, the combustion equation can be written as

The unknown coefficients  $x$ ,  $a$ , and  $b$  are determined from mass balances,

$$\text{N}_2 : 3.76a = 83.23 \longrightarrow a = 22.14$$

$$\text{C} : x = 5.20 + 0.33 \longrightarrow x = 5.53$$

$$\text{H} : 4x = 2b \longrightarrow b = 11.06$$

$$(\text{Check } \text{O}_2 : a = 5.20 + 0.165 + 11.24 + b/2 \longrightarrow 22.14 = 22.14)$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.53,

(a) The air-fuel ratio is determined from its definition,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(4.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(12 \text{ kg/kmol}) + (2 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{34.5 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2 : a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2.0$$

Then,

$$\text{Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(4.0)(4.76) \text{ kmol}}{(2.0)(4.76) \text{ kmol}} = \mathbf{200\%}$$

**15-39** Methyl alcohol is burned with 50% excess air. The combustion is incomplete. The mole fraction of carbon monoxide and the apparent molar mass of the products are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ ,  $\text{N}_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The balanced reaction equation for stoichiometric air is

The reaction with 50% excess air and incomplete combustion can be written as

The coefficient for CO is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 0.5 + 1.5 \times 1.5 = 0.9 + 0.05 + 1 + x \longrightarrow x = 0.8$$

Substituting,

The total moles of the products is

$$N_m = 0.9 + 0.10 + 2 + 0.8 + 8.46 = 12.26 \text{ kmol}$$

The mole fraction of carbon monoxide in the products is

$$y_{\text{CO}} = \frac{N_{\text{CO}}}{N_m} = \frac{0.8 \text{ kmol}}{12.26 \text{ kmol}} = \mathbf{0.0653}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{(0.9 \times 44 + 0.10 \times 28 + 2 \times 18 + 0.8 \times 32 + 8.46 \times 28) \text{ kg}}{12.26 \text{ kmol}} = \mathbf{27.80 \text{ kg/kmol}}$$

**15-40** n-Octane is burned with 100% excess air. The combustion is incomplete. The mole fractions of products and the dew-point temperature of the water vapor in the products are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ ,  $\text{N}_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion reaction for stoichiometric air is

The combustion equation with 100% excess air and incomplete combustion is

The coefficient for CO is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 25 = 0.85 \times 8 + 0.5 \times 0.15 \times 8 + 0.5 \times 9 + x \longrightarrow x = 13.1$$

Substituting,

The mole fractions of the products are

$$N_{\text{prod}} = 6.8 + 1.2 + 9 + 13.1 + 94 = 124.1 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{prod}}} = \frac{6.8 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.0548}$$

$$y_{\text{CO}} = \frac{N_{\text{CO}}}{N_{\text{prod}}} = \frac{1.2 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.0097}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{9 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.0725}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{prod}}} = \frac{13.1 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.1056}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{prod}}} = \frac{94 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.7575}$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left( \frac{9 \text{ kmol}}{124.1 \text{ kmol}} \right) (101.325 \text{ kPa}) = 7.348 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@7.348 \text{ kPa}} = \mathbf{39.9^\circ\text{C}} \quad (\text{Table A-5 or EES})$$

## Enthalpy of Formation and Enthalpy of Combustion

**15-41C** For combustion processes the enthalpy of reaction is referred to as the enthalpy of combustion, which represents the amount of heat released during a steady-flow combustion process.

**15-42C** Enthalpy of formation is the enthalpy of a substance due to its chemical composition. The enthalpy of formation is related to elements or compounds whereas the enthalpy of combustion is related to a particular fuel.

**15-43C** The heating value is called the higher heating value when the  $\text{H}_2\text{O}$  in the products is in the liquid form, and it is called the lower heating value when the  $\text{H}_2\text{O}$  in the products is in the vapor form. The heating value of a fuel is equal to the absolute value of the enthalpy of combustion of that fuel.

**15-44C** If the combustion of a fuel results in a single compound, the enthalpy of formation of that compound is identical to the enthalpy of combustion of that fuel.

**15-45C** Yes.

**15-46C** No. The enthalpy of formation of  $\text{N}_2$  is simply assigned a value of zero at the standard reference state for convenience.

**15-47C** 1 kmol of  $\text{H}_2$ . This is evident from the observation that when chemical bonds of  $\text{H}_2$  are destroyed to form  $\text{H}_2\text{O}$  a large amount of energy is released.

**15-48** The enthalpy of combustion of methane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

**Assumptions** The water in the products is in the liquid phase.

**Analysis** The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N<sub>2</sub> and O<sub>2</sub> are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of CH<sub>4</sub> becomes

$$h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{CH}_4}$$

Using  $\bar{h}_f^\circ$  values from Table A-26,

$$\begin{aligned} h_C &= (1 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (2 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-74,850 \text{ kJ/kmol}) \\ &= \mathbf{-890,330 \text{ kJ}} \text{ (per kmol CH}_4\text{)} \end{aligned}$$

The listed value in Table A-27 is -890,868 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this  $h_C$  value corresponds to the higher heating value of CH<sub>4</sub>.

**15-49 EES** Problem 15-48 is reconsidered. The effect of temperature on the enthalpy of combustion is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

**15-50** The enthalpy of combustion of gaseous ethane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

**Assumptions** The water in the products is in the liquid phase.

**Analysis** The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N<sub>2</sub> and O<sub>2</sub> are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of C<sub>2</sub>H<sub>6</sub> becomes

$$h_c = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{C}_2\text{H}_6}$$

Using  $\bar{h}_f^\circ$  values from Table A-26,

$$\begin{aligned} h_c &= (2 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (3 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-84,680 \text{ kJ/kmol}) \\ &= \mathbf{-1,559,850 \text{ kJ}} \text{ (per kmol C}_2\text{H}_6\text{)} \end{aligned}$$

The listed value in Table A-27 is -1,560,633 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this  $h_c$  value corresponds to the higher heating value of C<sub>2</sub>H<sub>6</sub>.

**15-51** The enthalpy of combustion of liquid octane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

**Assumptions** The water in the products is in the liquid phase.

**Analysis** The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N<sub>2</sub> and O<sub>2</sub> are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of C<sub>8</sub>H<sub>18</sub> becomes

$$h_c = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{C}_8\text{H}_{18}}$$

Using  $\bar{h}_f^\circ$  values from Table A-26,

$$\begin{aligned} h_c &= (8 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (9 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-249,950 \text{ kJ/kmol}) \\ &= \mathbf{-5,470,680 \text{ kJ}} \end{aligned}$$

The listed value in Table A-27 is -5,470,523 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this  $h_c$  value corresponds to the higher heating value of C<sub>8</sub>H<sub>18</sub>.

**15-52** Ethane is burned with stoichiometric amount of air. The heat transfer is to be determined if both the reactants and products are at 25°C.

**Assumptions** The water in the products is in the vapor phase.

**Analysis** The stoichiometric equation for this reaction is

Since both the reactants and the products are at the standard reference state of 25°C and 1 atm, the heat transfer for this process is equal to enthalpy of combustion. Note that  $\text{N}_2$  and  $\text{O}_2$  are stable elements, and thus their enthalpy of formation is zero. Then,

$$Q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{C}_2\text{H}_6}$$

Using  $\bar{h}_f^\circ$  values from Table A-26,

$$\begin{aligned} Q = h_C &= (2 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (3 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-84,680 \text{ kJ/kmol}) \\ &= \mathbf{-1,427,820 \text{ kJ/kmol C}_2\text{H}_6} \end{aligned}$$

**15-53** Ethane is burned with stoichiometric amount of air at 1 atm and 25°C. The minimum pressure of the products which will assure that the water in the products will be in vapor form is to be determined.

**Assumptions** The water in the products is in the vapor phase.

**Analysis** The stoichiometric equation for this reaction is

At the minimum pressure, the product mixture will be saturated with water vapor and

$$P_v = P_{\text{sat}@25^\circ\text{C}} = 3.1698 \text{ kPa}$$

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{3 \text{ kmol}}{(2 + 3 + 13.16) \text{ kmol}} = 0.1652$$

The minimum pressure of the products is then

$$P_{\text{min}} = \frac{P_v}{y_v} = \frac{3.1698 \text{ kPa}}{0.1652} = \mathbf{19.2 \text{ kPa}}$$

**15-54** The higher and lower heating values of coal from Utah are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ , and  $\text{N}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ ,  $\text{N}_2$ , S, and air are 12, 2, 32, 28, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$\text{mf}_C = \frac{m_C}{m_{\text{total}}} = \frac{61.40 \text{ kg}}{(100 - 5.00) \text{ kg}} = \frac{61.40 \text{ kg}}{95.00 \text{ kg}} = 0.6463$$

$$\text{mf}_{\text{H}_2} = \frac{m_{\text{H}_2}}{m_{\text{total}}} = \frac{5.79 \text{ kg}}{95.00 \text{ kg}} = 0.06095$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{25.31 \text{ kg}}{95.00 \text{ kg}} = 0.2664$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1.09 \text{ kg}}{95.00 \text{ kg}} = 0.01147$$

$$\text{mf}_S = \frac{m_S}{m_{\text{total}}} = \frac{1.41 \text{ kg}}{95.00 \text{ kg}} = 0.01484$$

|                     |
|---------------------|
| 61.40% C            |
| 5.79% $\text{H}_2$  |
| 25.31% $\text{O}_2$ |
| 1.09% $\text{N}_2$  |
| 1.41% S             |
| 5.00% ash           |
| (by mass)           |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_C = \frac{m_C}{M_C} = \frac{61.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.1167 \text{ kmol}$$

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{5.79 \text{ kg}}{2 \text{ kg/kmol}} = 2.895 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{25.31 \text{ kg}}{32 \text{ kg/kmol}} = 0.7909 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{1.09 \text{ kg}}{28 \text{ kg/kmol}} = 0.0389 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{1.41 \text{ kg}}{32 \text{ kg/kmol}} = 0.0439 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 5.1167 + 2.895 + 0.7909 + 0.0389 + 0.0439 = 9.354 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{5.1167 \text{ kmol}}{9.354 \text{ kmol}} = 0.5471$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_m} = \frac{2.895 \text{ kmol}}{9.354 \text{ kmol}} = 0.3100$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.7909 \text{ kmol}}{9.354 \text{ kmol}} = 0.0846$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.0389 \text{ kmol}}{9.354 \text{ kmol}} = 0.00416$$

$$y_S = \frac{N_S}{N_m} = \frac{0.0439 \text{ kmol}}{9.354 \text{ kmol}} = 0.00469$$

Then, the combustion equation in this case may be written as

According to the species balances,

$$\text{O}_2 \text{ balance: } 0.0890 + a_{\text{th}} = 0.5758 + 0.5 \times 0.3258 + 0.00496 \longrightarrow a_{\text{th}} = 0.6547$$

$$\text{N}_2 \text{ balance: } k = 0.00438 + 3.76 \times 0.6547 = 2.466$$

Substituting,

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that C, S, H<sub>2</sub>, N<sub>2</sub> and O<sub>2</sub> are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} + (N \bar{h}_f^\circ)_{\text{SO}_2}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$h_C = (0.5758 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (0.3258 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ + (0.00496 \text{ kmol})(-297,100 \text{ kJ/kmol}) \\ = -321,200 \text{ kJ/kmol coal}$$

The apparent molecular weight of the coal is

$$M_m = \frac{m_m}{N_m} = \frac{(0.5758 \times 12 + 0.3258 \times 2 + 0.0890 \times 32 + 0.00438 \times 28 + 0.00496 \times 32) \text{ kg}}{(0.5758 + 0.3258 + 0.0890 + 0.00438 + 0.00496) \text{ kmol}} \\ = \frac{10.69 \text{ kg}}{1.000 \text{ kmol}} = 10.69 \text{ kg/kmol coal}$$

The HHV of the coal is then

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{321,200 \text{ kJ/kmol coal}}{10.69 \text{ kg/kmol coal}} = \mathbf{30,000 \text{ kJ/kg coal}}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$h_C = (0.5758 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (0.3258 \text{ kmol})(-241,820 \text{ kJ/kmol}) \\ + (0.00496 \text{ kmol})(-297,100 \text{ kJ/kmol}) \\ = -306,850 \text{ kJ/kmol coal}$$

The LHV of the coal is then

$$\text{LHV} = \frac{-h_C}{M_m} = \frac{306,850 \text{ kJ/kmol coal}}{10.69 \text{ kg/kmol coal}} = \mathbf{28,700 \text{ kJ/kg coal}}$$

**First Law Analysis of Reacting Systems**

**15-55C** In this case  $\Delta U + W_b = \Delta H$ , and the conservation of energy relation reduces to the form of the steady-flow energy relation.

**15-56C** The heat transfer will be the same for all cases. The excess oxygen and nitrogen enters and leaves the combustion chamber at the same state, and thus has no effect on the energy balance.

**15-57C** For case (b), which contains the maximum amount of nonreacting gases. This is because part of the chemical energy released in the combustion chamber is absorbed and transported out by the nonreacting gases.

**15-58** Propane is burned with an air-fuel ratio of 18. The heat transfer per kilogram of fuel burned when the temperature of the products is such that liquid water just begins to form in the products is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The reactants are at 25°C and 1 atm. 6 The fuel is in vapor phase.

**Properties** The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass of air per kmol of fuel is

$$\begin{aligned} m_{\text{air}} &= (AF)m_{\text{fuel}} \\ &= (18 \text{ kg air/kg fuel})(1 \times 44 \text{ kg/kmol fuel}) \\ &= 792 \text{ kg air/kmol fuel} \end{aligned}$$

The mole number of air per kmol of fuel is then

$$N_{\text{air}} = \frac{m_{\text{air}}}{M_{\text{air}}} = \frac{792 \text{ kg air/kmol fuel}}{29 \text{ kg air/kmol air}} = 27.31 \text{ kmol air/kmol fuel}$$

The combustion equation can be written as

The coefficient for  $\text{O}_2$  is obtained from  $\text{O}_2$  balance:

$$(27.31/4.76) = 3 + 2 + x \longrightarrow x = 0.7374$$

Substituting,

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{4 \text{ kmol}}{(3 + 4 + 0.7374 + 21.57) \text{ kmol}} = \frac{4 \text{ kmol}}{29.31 \text{ kmol}} = 0.1365$$

The partial pressure of water vapor at 1 atm total pressure is

$$P_v = y_v P = (0.1365)(101.325 \text{ kPa}) = 13.83 \text{ kPa}$$

When this mixture is at the dew-point temperature, the water vapor pressure is the same as the saturation pressure. Then,

$$T_{\text{dp}} = T_{\text{sat}@13.83 \text{ kPa}} = 52.3^\circ\text{C} \cong 325 \text{ K}$$

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                     | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{325\text{K}}$<br>kJ/kmol |
|-------------------------------|------------------------------|------------------------------------|------------------------------------|
| C <sub>3</sub> H <sub>8</sub> | -103,850                     | ---                                | ---                                |
| O <sub>2</sub>                | 0                            | 8682                               | 9473                               |
| N <sub>2</sub>                | 0                            | 8669                               | 9452                               |
| H <sub>2</sub> O (g)          | -241,820                     | 9904                               | 10,808                             |
| CO <sub>2</sub>               | -393,520                     | 9364                               | 10,378                             |

Substituting,

$$\begin{aligned}
 -\bar{Q}_{\text{out}} &= (3)(-393,520 + 10,378 - 9364) + (4)(-241,820 + 10,808 - 9904) + (0.7374)(0 + 9473 - 8682) \\
 &\quad + (21.57)(0 + 9452 - 8669) - (1)(-103,850) - 0 \\
 &= -2,019,860 \text{ kJ/kmol C}_3\text{H}_8
 \end{aligned}$$

or

$$\bar{Q}_{\text{out}} = 2,019,860 \text{ kJ/kmol C}_3\text{H}_8$$

Then the heat transfer per kg of fuel is

$$Q_{\text{out}} = \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{2,019,860 \text{ kJ/kmol fuel}}{44 \text{ kg/kmol}} = \mathbf{45,900 \text{ kJ/kg C}_3\text{H}_8}$$

**15-59** n-Octane is burned with 100 percent excess air. The heat transfer per kilogram of fuel burned for a product temperature of 257°C is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The fuel is in vapor phase.

**Properties** The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion reaction for stoichiometric air is

The combustion equation with 100% excess air is

The heat transfer for this combustion process is determined from the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion

chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                     | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{530\text{K}}$<br>kJ/kmol |
|-------------------------------|------------------------------|------------------------------------|------------------------------------|
| $\text{C}_8\text{H}_{18} (g)$ | -208,450                     | ---                                | ---                                |
| $\text{O}_2$                  | 0                            | 8682                               | 15,708                             |
| $\text{N}_2$                  | 0                            | 8669                               | 15,469                             |
| $\text{H}_2\text{O} (g)$      | -241,820                     | 9904                               | 17,889                             |
| $\text{CO}_2$                 | -393,520                     | 9364                               | 19,029                             |

Substituting,

$$\begin{aligned} -\bar{Q}_{\text{out}} &= (8)(-393,520 + 19,029 - 9364) + (9)(-241,820 + 17,889 - 9904) + (12.5)(0 + 15,708 - 8682) \\ &\quad + (94)(0 + 15,469 - 8669) - (1)(-208,450) - 0 - 0 \\ &= -4,239,880 \text{ kJ/kmol C}_8\text{H}_{18} \end{aligned}$$

or  $\bar{Q}_{\text{out}} = 4,239,880 \text{ kJ/kmol C}_8\text{H}_{18}$

Then the heat transfer per kg of fuel is

$$Q_{\text{out}} = \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{4,239,880 \text{ kJ/kmol fuel}}{114 \text{ kg/kmol}} = \mathbf{37,200 \text{ kJ/kg C}_8\text{H}_{18}}$$

**15-60** A certain coal is burned steadily with 40% excess air. The heat transfer for a given product temperature is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ , and  $\text{N}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ , S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$\text{mf}_\text{C} = \frac{m_\text{C}}{m_\text{total}} = \frac{39.25 \text{ kg}}{(100 - 11.20) \text{ kg}} = \frac{39.25 \text{ kg}}{88.80 \text{ kg}} = 0.4420$$

$$\text{mf}_\text{H}_2 = \frac{m_\text{H}_2}{m_\text{total}} = \frac{6.93 \text{ kg}}{88.80 \text{ kg}} = 0.07804$$

$$\text{mf}_\text{O}_2 = \frac{m_\text{O}_2}{m_\text{total}} = \frac{41.11 \text{ kg}}{88.80 \text{ kg}} = 0.4630$$

$$\text{mf}_\text{N}_2 = \frac{m_\text{N}_2}{m_\text{total}} = \frac{0.72 \text{ kg}}{88.80 \text{ kg}} = 0.00811$$

$$\text{mf}_\text{S} = \frac{m_\text{S}}{m_\text{total}} = \frac{0.79 \text{ kg}}{88.80 \text{ kg}} = 0.00890$$

|                     |
|---------------------|
| 39.25% C            |
| 6.93% $\text{H}_2$  |
| 41.11% $\text{O}_2$ |
| 0.72% $\text{N}_2$  |
| 0.79% S             |
| 11.20% ash          |
| (by mass)           |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_\text{C} = \frac{m_\text{C}}{M_\text{C}} = \frac{44.20 \text{ kg}}{12 \text{ kg/kmol}} = 3.683 \text{ kmol}$$

$$N_\text{H}_2 = \frac{m_\text{H}_2}{M_\text{H}_2} = \frac{7.804 \text{ kg}}{2 \text{ kg/kmol}} = 3.902 \text{ kmol}$$

$$N_\text{O}_2 = \frac{m_\text{O}_2}{M_\text{O}_2} = \frac{46.30 \text{ kg}}{32 \text{ kg/kmol}} = 1.447 \text{ kmol}$$

$$N_\text{N}_2 = \frac{m_\text{N}_2}{M_\text{N}_2} = \frac{0.811 \text{ kg}}{28 \text{ kg/kmol}} = 0.0290 \text{ kmol}$$

$$N_\text{S} = \frac{m_\text{S}}{M_\text{S}} = \frac{0.890 \text{ kg}}{32 \text{ kg/kmol}} = 0.0278 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 3.683 + 3.902 + 1.447 + 0.0290 + 0.0278 = 9.089 \text{ kmol}$$

$$y_\text{C} = \frac{N_\text{C}}{N_m} = \frac{3.683 \text{ kmol}}{9.089 \text{ kmol}} = 0.4052$$

$$y_\text{H}_2 = \frac{N_\text{H}_2}{N_m} = \frac{3.902 \text{ kmol}}{9.089 \text{ kmol}} = 0.4293$$

$$y_\text{O}_2 = \frac{N_\text{O}_2}{N_m} = \frac{1.447 \text{ kmol}}{9.089 \text{ kmol}} = 0.1592$$

$$y_\text{N}_2 = \frac{N_\text{N}_2}{N_m} = \frac{0.0290 \text{ kmol}}{9.089 \text{ kmol}} = 0.00319$$

$$y_\text{S} = \frac{N_\text{S}}{N_m} = \frac{0.0278 \text{ kmol}}{9.089 \text{ kmol}} = 0.00306$$

Then, the combustion equation in this case may be written as

According to the  $\text{O}_2$  mass balance,

$$0.1592 + 1.4a_{\text{th}} = 0.4052 + 0.5 \times 0.4293 + 0.4a_{\text{th}} + 0.00306 \longrightarrow a_{\text{th}} = 0.4637$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{400\text{K}}$<br>kJ/kmol |
|--------------------------|------------------------------|------------------------------------|------------------------------------|
| $\text{O}_2$             | 0                            | 8682                               | 11,711                             |
| $\text{N}_2$             | 0                            | 8669                               | 11,640                             |
| $\text{H}_2\text{O} (g)$ | -241,820                     | 9904                               | 13,356                             |
| $\text{CO}_2$            | -393,520                     | 9364                               | 13,372                             |
| $\text{SO}_2$            | -297,100                     | -                                  | -                                  |

The enthalpy change of sulfur dioxide between the standard temperature and the product temperature using constant specific heat assumption is

$$\Delta \bar{h}_{\text{SO}_2} = c_p \Delta T = (41.7 \text{ kJ/kmol} \cdot \text{K})(127 - 25)\text{K} = 4253 \text{ kJ/kmol}$$

Substituting into the energy balance relation,

$$-\bar{Q}_{\text{out}} = (0.4052)(-393,520 + 13,372 - 9364) + (0.4293)(-241,820 + 13,356 - 9904) \\ + (0.1855)(0 + 11,711 - 8682) + (2.441)(0 + 11,640 - 8669) + (0.00306)(-297,100 + 4253) - 0 \\ = -253,244 \text{ kJ/kmol C}_8\text{H}_{18}$$

or  $\bar{Q}_{\text{out}} = 253,244 \text{ kJ/kmol C}_8\text{H}_{18}$

Then the heat transfer per kg of fuel is

$$Q_{\text{out}} = \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{253,244 \text{ kJ/kmol fuel}}{(0.4052 \times 12 + 0.4293 \times 2 + 0.1592 \times 32 + 0.00319 \times 28 + 0.00306 \times 32) \text{ kg/kmol}} \\ = \frac{253,244 \text{ kJ/kmol fuel}}{11.00 \text{ kg/kmol}} = \mathbf{23,020 \text{ kJ/kg coal}}$$

**15-61** Methane is burned completely during a steady-flow combustion process. The heat transfer from the combustion chamber is to be determined for two cases.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

**Analysis** The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only  $\text{H}_2\text{O}$ ,  $\text{CO}_2$  and  $\text{N}_2$ , but no free  $\text{O}_2$ . Considering 1 kmol of fuel, the theoretical combustion equation can be written as

where  $a_{\text{th}}$  is determined from the  $\text{O}_2$  balance,

$$a_{\text{th}} = 1 + 1 = 2$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ$$

since both the reactants and the products are at  $25^\circ\text{C}$  and both the air and the combustion gases can be treated as ideal gases. From the tables,

| Substance                   | $\bar{h}_f^\circ$<br>kJ/kmol |
|-----------------------------|------------------------------|
| $\text{CH}_4$               | -74,850                      |
| $\text{O}_2$                | 0                            |
| $\text{N}_2$                | 0                            |
| $\text{H}_2\text{O} (\ell)$ | -285,830                     |
| $\text{CO}_2$               | -393,520                     |

Thus,

$$-Q_{\text{out}} = (1)(-393,520) + (2)(-285,830) + 0 - (1)(-74,850) - 0 - 0 = -890,330 \text{ kJ / kmol CH}_4$$

or

$$Q_{\text{out}} = 890,330 \text{ kJ / kmol CH}_4$$

If combustion is achieved with 100% excess air, the answer would still be the same since it would enter and leave at  $25^\circ\text{C}$ , and absorb no energy.

**15-62** Liquid propane is burned with 150 percent excess air during a steady-flow combustion process. The mass flow rate of air and the rate of heat transfer from the combustion chamber are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

**Properties** The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The fuel is burned completely with excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol of  $\text{C}_3\text{H}_8$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$2.5a_{\text{th}} = 3 + 2 + 1.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Thus,

(a) The air-fuel ratio for this combustion process is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = 39.22 \text{ kg air/kg fuel}$$

Thus,  $\dot{m}_{\text{air}} = (\text{AF})(\dot{m}_{\text{fuel}}) = (39.22 \text{ kg air/kg fuel})(1.2 \text{ kg fuel/min}) = \mathbf{47.1 \text{ kg air/min}}$

(b) The heat transfer for this combustion process is determined from the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                    | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{285 \text{ K}}$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{1200 \text{ K}}$<br>kJ/kmol |
|------------------------------|------------------------------|--------------------------------------|--------------------------------------|---------------------------------------|
| $\text{C}_3\text{H}_8(\ell)$ | -118,910                     | ---                                  | ---                                  | ---                                   |
| $\text{O}_2$                 | 0                            | 8296.5                               | 8682                                 | 38,447                                |
| $\text{N}_2$                 | 0                            | 8286.5                               | 8669                                 | 36,777                                |
| $\text{H}_2\text{O}(g)$      | -241,820                     | ---                                  | 9904                                 | 44,380                                |
| $\text{CO}_2$                | -393,520                     | ---                                  | 9364                                 | 53,848                                |

The  $\bar{h}_f^\circ$  of liquid propane is obtained by adding  $\bar{h}_{fg}$  of propane at  $25^\circ\text{C}$  to  $\bar{h}_f^\circ$  of gas propane.

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (3)(-393,520 + 53,848 - 9364) + (4)(-241,820 + 44,380 - 9904) + (7.5)(0 + 38,447 - 8682) \\ &\quad + (47)(0 + 36,777 - 8669) - (1)(-118,910 + h_{298} - h_{298}) - (12.5)(0 + 8296.5 - 8682) \\ &\quad - (47)(0 + 8286.5 - 8669) \\ &= -190,464 \text{ kJ/kmol C}_3\text{H}_8 \end{aligned}$$

or  $Q_{\text{out}} = 190,464 \text{ kJ/kmol C}_3\text{H}_8$

Then the rate of heat transfer for a mass flow rate of 1.2 kg/min for the propane becomes

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = \left( \frac{\dot{m}}{N} \right) Q_{\text{out}} = \left( \frac{1.2 \text{ kg/min}}{44 \text{ kg/kmol}} \right) (190,464 \text{ kJ/kmol}) = \mathbf{5194 \text{ kJ/min}}$$

**15-63E** Liquid octane is burned with 180 percent theoretical air during a steady-flow combustion process. The AF ratio and the heat transfer from the combustion chamber are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

**Properties** The molar masses of  $C_8H_{18}$  and air are 54 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $CO_2$ ,  $H_2O$ ,  $N_2$ , and some free  $O_2$ . Considering 1 kmol of  $C_8H_{18}$ , the combustion equation can be written as

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$1.8a_{th} = 8 + 4.5 + 0.8a_{th} \longrightarrow a_{th} = 12.5$$

Thus,

$$(a) \quad AF = \frac{m_{air}}{m_{fuel}} = \frac{(22.5 \times 4.76 \text{ lbmol})(29 \text{ lbm/lbmol})}{(8 \text{ lbmol})(12 \text{ lbm/lbmol}) + (9 \text{ lbmol})(2 \text{ lbm/lbmol})} = 27.2 \text{ lbmair/lbmfuel}$$

(b) The heat transfer for this combustion process is determined from the energy balance

$E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}$$

since all of the reactants are at 77°F. Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance         | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{537 R}$<br>Btu/lbmol | $\bar{h}_{2500 R}$<br>Btu/lbmol |
|-------------------|--------------------------------|--------------------------------|---------------------------------|
| $C_8H_{18}(\ell)$ | -107,530                       | ---                            | ---                             |
| $O_2$             | 0                              | 3725.1                         | 19,443                          |
| $N_2$             | 0                              | 3729.5                         | 18,590                          |
| $CO_2$            | -169,300                       | 4027.5                         | 27,801                          |
| $H_2O(g)$         | -104,040                       | 4258.0                         | 22,735                          |

Thus,

$$\begin{aligned} -Q_{out} &= (8)(-169,300 + 27,801 - 4027.5) + (9)(-104,040 + 22,735 - 4258) + (10)(0 + 19,443 - 3725.1) \\ &\quad + (84.6)(0 + 18,590 - 3729.5) - (1)(-107,530) - 0 - 0 \\ &= -412,372 \text{ Btu/lbmol } C_8H_{18} \end{aligned}$$

or  $Q_{out} = 412,372 \text{ Btu/lbmol } C_8H_{18}$

**15-64** Benzene gas is burned with 95 percent theoretical air during a steady-flow combustion process. The mole fraction of the CO in the products and the heat transfer from the combustion chamber are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible.

**Analysis** (a) The fuel is burned with insufficient amount of air, and thus the products will contain some CO as well as CO<sub>2</sub>, H<sub>2</sub>O, and N<sub>2</sub>. The theoretical combustion equation of C<sub>6</sub>H<sub>6</sub> is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the O<sub>2</sub> balance,

$$a_{\text{th}} = 6 + 1.5 = 7.5$$

Then the actual combustion equation can be written as

$$\text{O}_2 \text{ balance: } 0.95 \times 7.5 = x + (6 - x)/2 + 1.5 \longrightarrow x = 5.25$$

The mole fraction of CO in the products is

$$y_{\text{CO}} = \frac{N_{\text{CO}}}{N_{\text{total}}} = \frac{0.75}{5.25 + 0.75 + 3 + 26.79} = 0.021 \text{ or } 2.1\%$$

(b) The heat transfer for this combustion process is determined from the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 25°C. Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                         | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{1000 \text{ K}}$<br>kJ/kmol |
|-----------------------------------|------------------------------|--------------------------------------|---------------------------------------|
| C <sub>6</sub> H <sub>6</sub> (g) | 82,930                       | ---                                  | ---                                   |
| O <sub>2</sub>                    | 0                            | 8682                                 | 31,389                                |
| N <sub>2</sub>                    | 0                            | 8669                                 | 30,129                                |
| H <sub>2</sub> O (g)              | -241,820                     | 9904                                 | 35,882                                |
| CO                                | -110,530                     | 8669                                 | 30,355                                |
| CO <sub>2</sub>                   | -393,520                     | 9364                                 | 42,769                                |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (5.25)(-393,520 + 42,769 - 9364) + (0.75)(-110,530 + 30,355 - 8669) \\ &\quad + (3)(-241,820 + 35,882 - 9904) + (26.79)(0 + 30,129 - 8669) - (1)(82,930) - 0 - 0 \\ &= -2,112,779 \text{ kJ / kmol C}_6\text{H}_6 \end{aligned}$$

$$\text{or } \dot{Q}_{\text{out}} = 2,112,800 \text{ kJ/kmol C}_6\text{H}_6$$

**15-65E** Diesel fuel is burned with 20 percent excess air during a steady-flow combustion process. The required mass flow rate of the diesel fuel for a specified heat transfer rate is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol of  $\text{C}_{12}\text{H}_{26}$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1.2a_{\text{th}} = 12 + 6.5 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 18.5$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 77°F. Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                    | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{537\text{ R}}$<br>Btu/lbmol | $\bar{h}_{800\text{ R}}$<br>Btu/lbmol |
|------------------------------|--------------------------------|---------------------------------------|---------------------------------------|
| $\text{C}_{12}\text{H}_{26}$ | -125,190                       | ---                                   | ---                                   |
| $\text{O}_2$                 | 0                              | 3725.1                                | 5602.0                                |
| $\text{N}_2$                 | 0                              | 3729.5                                | 5564.4                                |
| $\text{H}_2\text{O} (g)$     | -104,040                       | 4258.0                                | 6396.9                                |
| $\text{CO}_2$                | -169,300                       | 4027.5                                | 6552.9                                |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (12)(-169,300 + 6552.9 - 4027.5) + (13)(-104,040 + 6396.9 - 4258) \\ &\quad + (3.7)(0 + 5602.0 - 3725.1) + (83.47)(0 + 5564.4 - 3729.5) - (1)(-125,190) - 0 - 0 \\ &= -3,040,716 \text{ Btu/lbmol } \text{C}_{12}\text{H}_{26} \end{aligned}$$

or  $Q_{\text{out}} = 3,040,716 \text{ Btu/lbmol } \text{C}_{12}\text{H}_{26}$

Then the required mass flow rate of fuel for a heat transfer rate of 1800 Btu/s becomes

$$\dot{m} = \dot{N}M = \left( \frac{\dot{Q}}{Q} \right) M = \left( \frac{1800 \text{ Btu/s}}{3,040,716 \text{ Btu/lbmol}} \right) (170 \text{ lbm/lbmol}) = \mathbf{0.1006 \text{ lbm/s}}$$

**15-66 [Also solved by EES on enclosed CD]** Octane gas is burned with 30 percent excess air during a steady-flow combustion process. The heat transfer per unit mass of octane is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

**Properties** The molar mass of  $C_8H_{18}$  is 114 kg/kmol (Table A-1).

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $CO_2$ ,  $H_2O$ ,  $N_2$ , and some free  $O_2$ . The moisture in the air does not react with anything; it simply shows up as additional  $H_2O$  in the products. Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of  $C_8H_{18}$ , the combustion equation can be written as

where  $a_{th}$  is the stoichiometric coefficient for air. It is determined from

$$O_2 \text{ balance: } 1.3a_{th} = 8 + 4.5 + 0.3a_{th} \longrightarrow a_{th} = 12.5$$

Thus,

Therefore,  $16.25 \times 4.76 = 77.35$  kmol of dry air will be used per kmol of the fuel. The partial pressure of the water vapor present in the incoming air is

$$P_{v,in} = \phi_{air} P_{sat@25^\circ C} = (0.60)(3.1698 \text{ kPa}) = 1.902 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture that accompanies 77.35 kmol of incoming dry air is determined to be

$$N_{v,in} = \left( \frac{P_{v,in}}{P_{total}} \right) N_{total} = \left( \frac{1.902 \text{ kPa}}{101.325 \text{ kPa}} \right) (77.35 + N_{v,in}) \longrightarrow N_{v,in} = 1.48 \text{ kmol}$$

The balanced combustion equation is obtained by adding 1.48 kmol of  $H_2O$  to both sides of the equation,

The heat transfer for this combustion process is determined from the energy balance  $E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at  $25^\circ C$ . Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance      | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{600 \text{ K}}$<br>kJ/kmol |
|----------------|------------------------------|--------------------------------------|--------------------------------------|
| $C_8H_{18}(g)$ | -208,450                     | ---                                  | ---                                  |
| $O_2$          | 0                            | 8682                                 | 17,929                               |
| $N_2$          | 0                            | 8669                                 | 17,563                               |
| $H_2O(g)$      | -241,820                     | 9904                                 | 20,402                               |
| $CO_2$         | -393,520                     | 9364                                 | 22,280                               |

Substituting,

$$\begin{aligned} -Q_{out} &= (8)(-393,520 + 22,280 - 9364) + (10.48)(-241,820 + 20,402 - 9904) \\ &\quad + (3.75)(0 + 17,929 - 8682) + (61.1)(0 + 17,563 - 8669) \\ &\quad - (1)(-208,450) - (1.48)(-241,820) - 0 - 0 \\ &= -4,324,643 \text{ kJ/kmol } C_8H_{18} \end{aligned}$$

Thus 4,324,643 kJ of heat is transferred from the combustion chamber for each kmol (114 kg) of  $C_8H_{18}$ . Then the heat transfer per kg of  $C_8H_{18}$  becomes

$$q = \frac{Q_{out}}{M} = \frac{4,324,643 \text{ kJ}}{114 \text{ kg}} = 37,935 \text{ kJ/kg } C_8H_{18}$$

**15-67 EES** Problem 15-66 is reconsidered. The effect of the amount of excess air on the heat transfer for the combustion process is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**15-68** Ethane gas is burned with stoichiometric amount of air during a steady-flow combustion process. The rate of heat transfer from the combustion chamber is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

**Properties** The molar mass of  $C_2H_6$  is 30 kg/kmol (Table A-1).

**Analysis** The theoretical combustion equation of  $C_2H_6$  is

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$a_{th} = 2 + 1.5 = 3.5$$

Then the actual combustion equation can be written as

The heat transfer for this combustion process is determined from the energy balance  $E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance   | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{500\text{ K}}$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{800\text{ K}}$<br>kJ/kmol |
|-------------|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| $C_2H_6(g)$ | -84,680                      | ---                                 | ---                                 | ---                                 |
| $O_2$       | 0                            | 14,770                              | 8682                                | 24,523                              |
| $N_2$       | 0                            | 14,581                              | 8669                                | 23,714                              |
| $H_2O(g)$   | -241,820                     | ---                                 | 9904                                | 27,896                              |
| CO          | -110,530                     | ---                                 | 8669                                | 23,844                              |
| $CO_2$      | -393,520                     | ---                                 | 9364                                | 32,179                              |

Thus,

$$\begin{aligned} -Q_{out} &= (1.9)(-393,520 + 32,179 - 9364) + (0.1)(-110,530 + 23,844 - 8669) \\ &\quad + (3)(-241,820 + 27,896 - 9904) + (0.05)(0 + 24,523 - 8682) + (13.16)(0 + 23,714 - 8669) \\ &\quad - (1)(-84,680 + h_{298} - h_{298}) - (3.5)(0 + 14,770 - 8682) - (13.16)(0 + 14,581 - 8669) \\ &= -1,201,005 \text{ kJ / kmol } C_2H_6 \end{aligned}$$

or  $Q_{out} = 1,201,005 \text{ kJ / kmol } C_2H_6$

Then the rate of heat transfer for a mass flow rate of 3 kg/h for the ethane becomes

$$\dot{Q}_{out} = \dot{N} Q_{out} = \left( \frac{\dot{m}}{M} \right) Q_{out} = \left( \frac{5 \text{ kg/h}}{30 \text{ kg/kmol}} \right) (1,201,005 \text{ kJ/kmol}) = \mathbf{200,170 \text{ kJ/h}}$$

**15-69 [Also solved by EES on enclosed CD]** A mixture of methane and oxygen contained in a tank is burned at constant volume. The final pressure in the tank and the heat transfer during this process are to be determined.

**Assumptions** 1 Air and combustion gases are ideal gases. 2 Combustion is complete.

**Properties** The molar masses of  $\text{CH}_4$  and  $\text{O}_2$  are 16 kg/kmol and 32 kg/kmol, respectively (Table A-1).

**Analysis** (a) The combustion is assumed to be complete, and thus all the carbon in the methane burns to  $\text{CO}_2$  and all of the hydrogen to  $\text{H}_2\text{O}$ . The number of moles of  $\text{CH}_4$  and  $\text{O}_2$  in the tank are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{0.12 \text{ kg}}{16 \text{ kg/kmol}} = 7.5 \times 10^{-3} \text{ kmol} = 7.5 \text{ mol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.6 \text{ kg}}{32 \text{ kg/kmol}} = 18.75 \times 10^{-3} \text{ kmol} = 18.75 \text{ mol}$$

Then the combustion equation can be written as

At 1200 K, water exists in the gas phase. Assuming both the reactants and the products to be ideal gases, the final pressure in the tank is determined to be

$$\left. \begin{array}{l} P_R \nu = N_R R_u T_R \\ P_P \nu = N_P R_u T_P \end{array} \right\} P_P = P_R \left( \frac{N_P}{N_R} \right) \left( \frac{T_P}{T_R} \right)$$

Substituting,

$$P_P = (200 \text{ kPa}) \left( \frac{26.25 \text{ mol}}{26.25 \text{ mol}} \right) \left( \frac{1200 \text{ K}}{298 \text{ K}} \right) = \mathbf{805 \text{ kPa}}$$

which is relatively low. Therefore, the ideal gas assumption utilized earlier is appropriate.

(b) The heat transfer for this constant volume combustion process is determined from the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{\nu})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{\nu})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{\nu}$  terms in this equation can be replaced by  $R_u T$ . It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1200 \text{ K}} - \bar{h}_{298 \text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{1200 \text{ K}}$<br>kJ/kmol |
|--------------------------|------------------------------|--------------------------------------|---------------------------------------|
| $\text{CH}_4$            | -74,850                      | ---                                  | ---                                   |
| $\text{O}_2$             | 0                            | 8682                                 | 38,447                                |
| $\text{H}_2\text{O} (g)$ | -241,820                     | 9904                                 | 44,380                                |
| $\text{CO}_2$            | -393,520                     | 9364                                 | 53,848                                |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (7.5)(-393,520 + 53,848 - 9364 - 8.314 \times 1200) \\ &\quad + (15)(-241,820 + 44,380 - 9904 - 8.314 \times 1200) \\ &\quad + (3.75)(0 + 38,447 - 8682 - 8.314 \times 1200) \\ &\quad - (7.5)(-74,850 - 8.314 \times 298) - (18.75)(-8.314 \times 298) \\ &= -5,251,791 \text{ J} = \mathbf{-5252 \text{ kJ}} \end{aligned}$$

Thus  $Q_{\text{out}} = \mathbf{5252 \text{ kJ}}$  of heat is transferred from the combustion chamber as 120 g of  $\text{CH}_4$  burned in this combustion chamber.

**15-70 EES** Problem 15-69 is reconsidered. The effect of the final temperature on the final pressure and the heat transfer for the combustion process is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

"Input Data"

**15-71** Propane is burned with 50% excess air. The heat transfer per kmol of fuel is to be determined for given reactants and products temperatures.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The reactants are at 17°C and 1 atm. 6 The fuel is in vapor phase.

**Properties** The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation can be written as

The stoichiometric coefficient is obtained from O<sub>2</sub> balance:

$$1.5a_{\text{th}} = 3 + 2 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                     | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{290\text{K}}$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{370\text{K}}$<br>kJ/kmol |
|-------------------------------|------------------------------|------------------------------------|------------------------------------|------------------------------------|
| C <sub>3</sub> H <sub>8</sub> | -103,850                     | ---                                | ---                                | ---                                |
| O <sub>2</sub>                | 0                            | 8443                               | 8682                               | 10,809                             |
| N <sub>2</sub>                | 0                            | 8432                               | 8669                               | 10,763                             |
| H <sub>2</sub> O (g)          | -241,820                     | -                                  | 9904                               | 12,331                             |
| CO <sub>2</sub>               | -393,520                     | -                                  | 9364                               | 12,148                             |

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (3)(-393,520 + 12,148 - 9364) + (4)(-241,820 + 12,331 - 9904) + (2.5)(0 + 10,809 - 8682) \\ &\quad + (28.2)(0 + 10,763 - 8669) - (1)(-103,850) - (7.5)(0 + 8443 - 8682) - (28.2)(0 + 8432 - 8669) \\ &= -1,953,000 \text{ kJ/kmol C}_3\text{H}_8 \end{aligned}$$

or  $Q_{\text{out}} = \mathbf{1,953,000 \text{ kJ/kmol C}_3\text{H}_8}$

**Discussion** We neglected the enthalpy difference of propane between the standard temperature 25°C and the given temperature 17°C since the data is not available. It may be shown that the contribution of this would be small.

**15-72E** Methane is burned with stoichiometric amount of air in a rigid container. The heat rejected from the container is to be determined.

**Assumptions** 1 Air and combustion gases are ideal gases. 2 Combustion is complete.

**Properties** The molar masses of  $\text{CH}_4$  and air are 16 lbm/lbmol and 29 lbm/lbmol, respectively (Table A-1E).

**Analysis** The combustion equation for 1 lbmol of fuel is

The heat transfer for this constant volume combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ . It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1300\text{R}} - \bar{h}_{537\text{R}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 77°F. From the tables,

| Substance                | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{537\text{R}}$<br>Btu/lbmol | $\bar{h}_{1300\text{R}}$<br>Btu/lbmol |
|--------------------------|--------------------------------|--------------------------------------|---------------------------------------|
| $\text{CH}_4$            | -32,210                        | ---                                  | ---                                   |
| $\text{O}_2$             | 0                              | 3725.1                               | 9412.9                                |
| $\text{N}_2$             | 0                              | 3729.5                               | 9153.9                                |
| $\text{H}_2\text{O} (g)$ | -104,040                       | 4258.0                               | 10,714.5                              |
| $\text{CO}_2$            | -169,300                       | 4027.5                               | 12,136.9                              |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-169,300 + 12,136.9 - 4027.5 - 1.9858 \times 1300) \\ &\quad + (2)(-104,040 + 10,714.5 - 4258.0 - 1.9858 \times 1300) \\ &\quad + (7.52)(0 + 9153.9 - 3729.5 - 1.9858 \times 1300) \\ &\quad - (1)(-32,210 - 1.9858 \times 537) - (2)(-1.9858 \times 537) - (7.52)(-1.9858 \times 537) \\ &= -299,300 \text{ Btu/lbmol CH}_4 \end{aligned}$$

Thus

$$Q_{\text{out}} = \mathbf{299,300 \text{ Btu/lbmol CH}_4}$$

**15-73** Wheat straw that is being considered as an alternative fuel is tested in a bomb calorimeter. The heating value of this straw is to be determined and compared to the higher heating value of propane.

**Assumptions 1** Combustion is complete.

**Analysis** The heat released by the combustion is

$$Q = mc_v \Delta T = (100 \text{ kJ/K})(1.8 \text{ K}) = 180 \text{ kJ}$$

The heating value is then

$$\text{HV} = \frac{Q}{m} = \frac{180 \text{ kJ}}{0.010 \text{ kg}} = \mathbf{18,000 \text{ kJ/kg}}$$

From Table A-27, the higher heating value of propane is

$$\text{HHV} = \mathbf{50,330 \text{ kJ/kg}}$$

**15-74** A mixture of benzene gas and 30 percent excess air contained in a constant-volume tank is ignited. The heat transfer from the combustion chamber is to be determined.

**Assumptions** 1 Both the reactants and products are ideal gases. 2 Combustion is complete.

**Analysis** The theoretical combustion equation of  $C_6H_6$  with stoichiometric amount of air is

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$a_{th} = 6 + 1.5 = 7.5$$

Then the actual combustion equation with 30% excess air becomes

The heat transfer for this constant volume combustion process is determined from the energy balance  $E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ .

It yields

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1000\text{ K}} - \bar{h}_{298\text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

| Substance   | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{1000\text{ K}}$<br>kJ/kmol |
|-------------|------------------------------|-------------------------------------|--------------------------------------|
| $C_6H_6(g)$ | 82,930                       | ---                                 | ---                                  |
| $O_2$       | 0                            | 8682                                | 31,389                               |
| $N_2$       | 0                            | 8669                                | 30,129                               |
| $H_2O(g)$   | -241,820                     | 9904                                | 35,882                               |
| CO          | -110,530                     | 8669                                | 30,355                               |
| $CO_2$      | -393,520                     | 9364                                | 42,769                               |

Thus,

$$\begin{aligned} -Q_{out} &= (5.52)(-393,520 + 42,769 - 9364 - 8.314 \times 1000) \\ &\quad + (0.48)(-110,530 + 30,355 - 8669 - 8.314 \times 1000) \\ &\quad + (3)(-241,820 + 35,882 - 9904 - 8.314 \times 1000) \\ &\quad + (2.49)(0 + 31,389 - 8682 - 8.314 \times 1000) \\ &\quad + (36.66)(0 + 30,129 - 8669 - 8.314 \times 1000) \\ &\quad - (1)(82,930 - 8.314 \times 298) - (9.75)(4.76)(-8.314 \times 298) \\ &= -2,200,433 \text{ kJ} \end{aligned}$$

or  $Q_{out} = 2,200,433 \text{ kJ}$

**15-75E** A mixture of benzene gas and 30 percent excess air contained in a constant-volume tank is ignited. The heat transfer from the combustion chamber is to be determined.

**Assumptions** 1 Both the reactants and products are ideal gases. 2 Combustion is complete.

**Analysis** The theoretical combustion equation of  $C_6H_6$  with stoichiometric amount of air is

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$a_{th} = 6 + 1.5 = 7.5$$

Then the actual combustion equation with 30% excess air becomes

The heat transfer for this constant volume combustion process is determined from the energy balance  $E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ .

It yields

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1800R} - \bar{h}_{537R} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 77°F. From the tables,

| Substance   | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{537R}$<br>Btu/lbmol | $\bar{h}_{1800R}$<br>Btu/lbmol |
|-------------|--------------------------------|-------------------------------|--------------------------------|
| $C_6H_6(g)$ | 35,6860                        | ---                           | ---                            |
| $O_2$       | 0                              | 3725.1                        | 13,485.8                       |
| $N_2$       | 0                              | 3729.5                        | 12,956.3                       |
| $H_2O(g)$   | -104,040                       | 4258.0                        | 15,433.0                       |
| CO          | -47,540                        | 3725.1                        | 13,053.2                       |
| $CO_2$      | -169,300                       | 4027.5                        | 18,391.5                       |

Thus,

$$\begin{aligned} -Q_{out} &= (5.52)(-169,300 + 18,391.5 - 4027.5 - 1.986 \times 1800) \\ &\quad + (0.48)(-47,540 + 13,053.2 - 3725.1 - 1.986 \times 1800) \\ &\quad + (3)(-104,040 + 15,433.0 - 4258.0 - 1.986 \times 1800) \\ &\quad + (2.49)(0 + 13,485.8 - 3725.1 - 1.986 \times 1800) \\ &\quad + (36.66)(0 + 12,956.3 - 3729.5 - 1.986 \times 1800) \\ &\quad - (1)(35,680 - 1.986 \times 537) - (9.75)(4.76)(-1.986 \times 537) \\ &= -946,870 \text{ Btu} \end{aligned}$$

or  $Q_{out} = 946,870 \text{ Btu}$

**15-76** A high efficiency gas furnace burns gaseous propane  $C_3H_8$  with 140 percent theoretical air. The volume flow rate of water condensed from the product gases is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $CO_2$ ,  $H_2O$ ,  $O_2$ , and  $N_2$  only.

**Properties** The molar masses of C,  $H_2$ ,  $O_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The reaction equation for 40% excess air (140% theoretical air) is

where  $a_{th}$  is the stoichiometric coefficient for air. We have automatically accounted for the 40% excess air by using the factor  $1.4a_{th}$  instead of  $a_{th}$  for air. The coefficient  $a_{th}$  and other coefficients are to be determined from the mass balances

Carbon balance:  $B = 3$

Hydrogen balance:  $2D = 8 \longrightarrow D = 4$

Oxygen balance:  $2 \times 1.4a_{th} = 2B + D + 2E$

$$0.4a_{th} = E$$

Nitrogen balance:  $1.4a_{th} \times 3.76 = F$

Solving the above equations, we find the coefficients ( $E = 2$ ,  $F = 26.32$ , and  $a_{th} = 5$ ) and write the balanced reaction equation as

The partial pressure of water in the saturated product mixture at the dew point is

$$P_{v,prod} = P_{sat@40^\circ C} = 7.3851 \text{ kPa}$$

The vapor mole fraction is

$$y_v = \frac{P_{v,prod}}{P_{prod}} = \frac{7.3851 \text{ kPa}}{100 \text{ kPa}} = 0.07385$$

The kmols of water condensed is determined from

$$y_v = \frac{N_{water}}{N_{total,product}} \longrightarrow 0.07385 = \frac{4 - N_w}{3 + 4 - N_w + 2 + 26.32} \longrightarrow N_w = 1.503 \text{ kmol}$$

The steady-flow energy balance is expressed as

$$\dot{N}_{fuel} H_R = \dot{Q}_{fuel} + \dot{N}_{fuel} H_P$$

where

$$\dot{Q}_{fuel} = \frac{\dot{Q}_{out}}{\eta_{furnace}} = \frac{31,650 \text{ kJ/h}}{0.96} = 32,969 \text{ kJ/h}$$

$$\begin{aligned} H_R &= \bar{h}_f^o_{fuel@25^\circ C} + 7\bar{h}_{O_2@25^\circ C} + 26.32\bar{h}_{N_2@25^\circ C} \\ &= (-103,847 \text{ kJ/kmol}) + 7(0) + 26.32(0) = -103,847 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned}
 H_P &= 3\bar{h}_{\text{CO}_2@25^\circ\text{C}} + 4\bar{h}_{\text{H}_2\text{O}@25^\circ\text{C}} + 2\bar{h}_{\text{O}_2@25^\circ\text{C}} + 26.32\bar{h}_{\text{N}_2@25^\circ\text{C}} + N_w(\bar{h}_f^o_{\text{H}_2\text{O}(\text{liq})}) \\
 &= 3(-393,520 \text{ kJ/kmol}) + 4(-241,820 \text{ kJ/kmol}) + 2(0) + 26.32(0) + 1.503(-285,830 \text{ kJ/kmol}) \\
 &= -2.577 \times 10^6 \text{ kJ/kmol}
 \end{aligned}$$

Substituting into the energy balance equation,

$$\begin{aligned}
 \dot{N}_{\text{fuel}} H_R &= \dot{Q}_{\text{fuel}} + \dot{N}_{\text{fuel}} H_P \\
 \dot{N}_{\text{fuel}} (-103,847 \text{ kJ/kmol}) &= 32,969 \text{ kJ/h} + \dot{N}_{\text{fuel}} (-2.577 \times 10^6 \text{ kJ/kmol}) \\
 \dot{N}_{\text{fuel}} &= 0.01333 \text{ kmol/h}
 \end{aligned}$$

The molar and mass flow rates of the liquid water are

$$\begin{aligned}
 \dot{N}_w &= N_w \dot{N}_{\text{fuel}} = (1.503 \text{ kmol/kmol fuel})(0.01333 \text{ kmol fuel/h}) = 0.02003 \text{ kmol/h} \\
 \dot{m}_w &= \dot{N}_w M_w = (0.02003 \text{ kmol/h})(18 \text{ kg/kmol}) = 0.3608 \text{ kg/h}
 \end{aligned}$$

The volume flow rate of liquid water is

$$\dot{V}_w = (\nu_{f@25^\circ\text{C}}) \dot{m}_w = (0.001003 \text{ m}^3/\text{kg})(0.3608 \text{ kg/h}) = 0.0003619 \text{ m}^3/\text{h} = \mathbf{0.362 \text{ L/day}}$$

**Adiabatic Flame Temperature**

**15-77C** For the case of stoichiometric amount of pure oxygen since we have the same amount of chemical energy released but a smaller amount of mass to absorb it.

**15-78C** Under the conditions of complete combustion with stoichiometric amount of air.

**15-79 [Also solved by EES on enclosed CD]** Hydrogen is burned with 20 percent excess air during a steady-flow combustion process. The exit temperature of product gases is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ( $Q = 0$ ) with no work interactions ( $W = 0$ ). Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

The combustion equation of  $\text{H}_2$  with 20% excess air is

From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{280\text{ K}}$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol |
|--------------------------|------------------------------|-------------------------------------|-------------------------------------|
| $\text{H}_2$             | 0                            | 7945                                | 8468                                |
| $\text{O}_2$             | 0                            | 8150                                | 8682                                |
| $\text{N}_2$             | 0                            | 8141                                | 8669                                |
| $\text{H}_2\text{O} (g)$ | -241,820                     | 9296                                | 9904                                |

Thus,

$$\begin{aligned} & (1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.1)(0 + \bar{h}_{\text{O}_2} - 8682) + (2.256)(0 + \bar{h}_{\text{N}_2} - 8669) \\ &= (1)(0 + 7945 - 8468) + (0.6)(0 + 8150 - 8682) + (2.256)(0 + 8141 - 8669) \end{aligned}$$

It yields

$$\bar{h}_{\text{H}_2\text{O}} + 0.1\bar{h}_{\text{O}_2} + 2.256\bar{h}_{\text{N}_2} = 270,116 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $270,116/(1 + 0.1 + 2.256) = 80,488 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 2400 K for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_p$  will be close to 2400 K, but somewhat under it because of the higher specific heat of  $\text{H}_2\text{O}$ .

$$\begin{aligned} \text{At } 2300 \text{ K: } \quad & \bar{h}_{\text{H}_2\text{O}} + 0.1\bar{h}_{\text{O}_2} + 2.256\bar{h}_{\text{N}_2} = (1)(98,199) + (0.1)(79,316) + (2.256)(75,676) \\ &= 276,856 \text{ kJ (Higher than 270,116 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At } 2250 \text{ K: } \quad & \bar{h}_{\text{H}_2\text{O}} + 0.1\bar{h}_{\text{O}_2} + 2.256\bar{h}_{\text{N}_2} = (1)(95,562) + (0.1)(77,397) + (2.256)(73,856) \\ &= 269,921 \text{ kJ (Lower than 270,116 kJ)} \end{aligned}$$

By interpolation,  $T_p = 2251.4 \text{ K}$

**15-80 EES** Problem 15-79 is reconsidered. This problem is to be modified to include the fuels butane, ethane, methane, and propane as well as H<sub>2</sub>; to include the effects of inlet air and fuel temperatures; and the percent theoretical air supplied.

**Analysis** The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel C<sub>x</sub>H<sub>y</sub> entering at T<sub>fuel</sub> with Stoichiometric Air at T<sub>air</sub>:

Reaction: C<sub>x</sub>H<sub>y</sub> + (y/4 + x) (Theo<sub>air</sub>/100) (O<sub>2</sub> + 3.76 N<sub>2</sub>)

**15-81E** Hydrogen is burned with 20 percent excess air during a steady-flow combustion process. The exit temperature of product gases is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ( $Q = 0$ ) with no work interactions ( $W = 0$ ). Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

The combustion equation of  $\text{H}_2$  with 20% excess air is

From the tables,

| Substance                | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{500\text{ R}}$<br>Btu/lbmol | $\bar{h}_{537\text{ R}}$<br>Btu/lbmol |
|--------------------------|--------------------------------|---------------------------------------|---------------------------------------|
| $\text{H}_2$             | 0                              | 3386.1                                | 3640.3                                |
| $\text{O}_2$             | 0                              | 3466.2                                | 3725.1                                |
| $\text{N}_2$             | 0                              | 3472.2                                | 3729.5                                |
| $\text{H}_2\text{O} (g)$ | -104,040                       | 3962.0                                | 4258.0                                |

Thus,

$$\begin{aligned} & (1)(-104,040 + \bar{h}_{\text{H}_2\text{O}} - 4258) + (0.1)(0 + \bar{h}_{\text{O}_2} - 3725.1) + (2.256)(0 + \bar{h}_{\text{N}_2} - 3729.5) \\ &= (1)(0 + 3386.1 - 3640.3) + (0.6)(0 + 3466.2 - 3725.1) + (2.256)(0 + 3472.2 - 3729.5) \end{aligned}$$

It yields

$$\bar{h}_{\text{H}_2\text{O}} + 0.1\bar{h}_{\text{O}_2} + 2.256\bar{h}_{\text{N}_2} = 116,094 \text{ Btu}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $116,094/(1 + 0.1 + 2.256) = 34,593 \text{ Btu/lbmol}$ . This enthalpy value corresponds to about 4400 R for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_P$  will be close to 4400 R, but somewhat under it because of the higher specific heat of  $\text{H}_2\text{O}$ .

$$\begin{aligned} \text{At } 4020 \text{ R: } \quad & \bar{h}_{\text{H}_2\text{O}} + 0.1\bar{h}_{\text{O}_2} + 2.256\bar{h}_{\text{N}_2} = (1)(40,740) + (0.1)(32,989) + (2.256)(31,503) \\ &= 115,110 \text{ Btu (Lower than 116,094 Btu)} \end{aligned}$$

$$\begin{aligned} \text{At } 4100 \text{ R: } \quad & \bar{h}_{\text{H}_2\text{O}} + 0.1\bar{h}_{\text{O}_2} + 2.256\bar{h}_{\text{N}_2} = (1)(41,745) + (0.1)(33,722) + (2.256)(32,198) \\ &= 117,756 \text{ Btu (Higher than 116,094 Btu)} \end{aligned}$$

By interpolation,  $T_P = 4054 \text{ R}$

**15-82** Methane is burned with 30 percent excess air. The adiabatic flame temperature is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $Q = W = 0$  reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

since all the reactants are at the standard reference temperature of 25°C. Then,

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1.3a_{\text{th}} = 1 + 1 + 0.3a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

From the tables,

| Substance               | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol |
|-------------------------|------------------------------|------------------------------------|
| $\text{H}_4(g)$         | -74,850                      | ---                                |
| $\text{O}_2$            | 0                            | 8682                               |
| $\text{N}_2$            | 0                            | 8669                               |
| $\text{H}_2\text{O}(g)$ | -241,820                     | 9904                               |
| $\text{CO}_2$           | -393,520                     | 9364                               |

Thus,

$$(1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.3)(0 + \bar{h}_{\text{O}_2} - 8682) + (9.776)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-74,850) + 0 + 0$$

$$\text{It yields } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 0.3\bar{h}_{\text{O}_2} + 9.776\bar{h}_{\text{N}_2} = 918,835 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $918,835/(1 + 2 + 0.3 + 9.776) = 70,269 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 2150 K for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_p$  will be close to 2150 K, but somewhat under it because of the higher specific heat of  $\text{H}_2\text{O}$ .

At 2000 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 0.3\bar{h}_{\text{O}_2} + 9.776\bar{h}_{\text{N}_2} = 100,804 + 2 \times 82,593 + 0.3 \times 67,881 + 9.776 \times 64,810 = 919,936 \text{ kJ (Higher than 918,835 kJ)}$$

At 1980 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 0.3\bar{h}_{\text{O}_2} + 9.776\bar{h}_{\text{N}_2} = 99,606 + 2 \times 81,573 + 0.3 \times 67,127 + 9.776 \times 64,090 = 909,434 \text{ kJ (Lower than 918,835 kJ)}$$

By interpolation,  $T_p = \mathbf{1998 \text{ K} = 1725^\circ\text{C}}$

**15-83** Octane is burned with 40 percent excess air adiabatically during a steady-flow combustion process. The exit temperature of product gases is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $Q = W = 0$  reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

since all the reactants are at the standard reference temperature of 25°C. Then,

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1.4a_{\text{th}} = 8 + 4.5 + 0.4a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

From the tables,

| Substance                    | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{580\text{K}}$<br>kJ/kmol |
|------------------------------|------------------------------|------------------------------------|------------------------------------|
| $\text{C}_8\text{H}_{18}(l)$ | -249,950                     | ---                                | ---                                |
| $\text{O}_2$                 | 0                            | 8682                               | 17,290                             |
| $\text{N}_2$                 | 0                            | 8669                               | 16,962                             |
| $\text{H}_2\text{O}(g)$      | -241,820                     | 9904                               | ---                                |
| $\text{CO}_2$                | -393,520                     | 9364                               | ---                                |

Thus,

$$(8)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (9)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (5)(0 + \bar{h}_{\text{O}_2} - 8682) + (65.8)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-249,950) + (17.5)(0 + 17,290 - 8682) + (65.8)(16,962 - 8669)$$

$$\text{It yields } 8\bar{h}_{\text{CO}_2} + 9\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 65.8\bar{h}_{\text{N}_2} = 6,548,788 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $6,548,788 / (8 + 9 + 5 + 65.8) = 74,588 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 2250 K for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_P$  will be close to 2250 K, but somewhat under it because of the higher specific heat of  $\text{H}_2\text{O}$ .

At 2100 K:

$$8\bar{h}_{\text{CO}_2} + 9\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 65.8\bar{h}_{\text{N}_2} = (8)(106,864) + (9)(87,735) + (5)(71,668) + (65.8)(68,417) = 6,504,706 \text{ kJ (Lower than 6,548,788 kJ)}$$

At 2150 K:

$$8\bar{h}_{\text{CO}_2} + 9\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 65.8\bar{h}_{\text{N}_2} = (8)(109,898) + (9)(90,330) + (5)(73,573) + (65.8)(70,226) = 6,680,890 \text{ kJ (Higher than 6,548,788 kJ)}$$

By interpolation,  $T_P = 2113 \text{ K} = 1840^\circ\text{C}$

**15-84** A certain coal is burned with 50 percent excess air adiabatically during a steady-flow combustion process. The temperature of product gases is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Properties** The molar masses of C, H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$mf_C = \frac{m_C}{m_{\text{total}}} = \frac{79.61 \text{ kg}}{(100 - 8.62) \text{ kg}} = \frac{79.61 \text{ kg}}{91.38 \text{ kg}} = 0.8712$$

$$mf_{H_2} = \frac{m_{H_2}}{m_{\text{total}}} = \frac{4.66 \text{ kg}}{91.38 \text{ kg}} = 0.05100$$

$$mf_{O_2} = \frac{m_{O_2}}{m_{\text{total}}} = \frac{4.76 \text{ kg}}{91.38 \text{ kg}} = 0.05209$$

$$mf_{N_2} = \frac{m_{N_2}}{m_{\text{total}}} = \frac{1.83 \text{ kg}}{91.38 \text{ kg}} = 0.02003$$

$$mf_S = \frac{m_S}{m_{\text{total}}} = \frac{0.52 \text{ kg}}{91.38 \text{ kg}} = 0.00569$$

|                      |
|----------------------|
| 79.61% C             |
| 4.66% H <sub>2</sub> |
| 4.76% O <sub>2</sub> |
| 1.83% N <sub>2</sub> |
| 0.52% S              |
| 8.62% ash            |
| (by mass)            |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_C = \frac{m_C}{M_C} = \frac{87.12 \text{ kg}}{12 \text{ kg/kmol}} = 7.26 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.10 \text{ kg}}{2 \text{ kg/kmol}} = 2.55 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{5.209 \text{ kg}}{32 \text{ kg/kmol}} = 0.1628 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{2.003 \text{ kg}}{28 \text{ kg/kmol}} = 0.07154 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.569 \text{ kg}}{32 \text{ kg/kmol}} = 0.01778 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 7.26 + 2.55 + 0.1628 + 0.07154 + 0.01778 = 10.062 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{7.26 \text{ kmol}}{10.06 \text{ kmol}} = 0.7215$$

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.55 \text{ kmol}}{10.06 \text{ kmol}} = 0.2535$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.1628 \text{ kmol}}{10.06 \text{ kmol}} = 0.01618$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.07154 \text{ kmol}}{10.06 \text{ kmol}} = 0.00711$$

$$y_S = \frac{N_S}{N_m} = \frac{0.01778 \text{ kmol}}{10.06 \text{ kmol}} = 0.00177$$

Then, the combustion equation in this case may be written as

According to the species balances,

$$\text{C balance: } x = 0.7215$$

$$\text{H}_2 \text{ balance: } y = 0.2535$$

$$\text{S balance: } z = 0.00177$$

$$\text{O}_2 \text{ balance:}$$

$$0.01618 + 1.5a_{\text{th}} = x + 0.5y + z + 0.5a_{\text{th}}$$

$$1.5a_{\text{th}} - 0.5a_{\text{th}} = 0.7215 + 0.5(0.2535) + 0.00177 - 0.01617 \longrightarrow a_{\text{th}} = 0.8339$$

$$\text{N}_2 \text{ balance: } 0.00711 + 1.5 \times 3.76a_{\text{th}} = k \longrightarrow k = 0.00711 + 1.5 \times 3.76 \times 0.8339 = 4.710$$

Substituting,

$$0.7215\text{C} + 0.2535\text{H}_2 + 0.01617\text{O}_2 + 0.00711\text{N}_2 + 0.00177\text{S} + 1.2509(\text{O}_2 + 3.76\text{N}_2) \\ \longrightarrow 0.7215\text{CO}_2 + 0.2535\text{H}_2\text{O} + 0.0018\text{SO}_2 + 4.71\text{N}_2 + 0.4170\text{O}_2$$

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $Q = W = 0$  reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

From the tables,

| Substance            | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{400\text{K}}$<br>kJ/kmol |
|----------------------|------------------------------|------------------------------------|------------------------------------|
| O <sub>2</sub>       | 0                            | 8682                               | 11,711                             |
| N <sub>2</sub>       | 0                            | 8669                               | 11,640                             |
| H <sub>2</sub> O (g) | -241,820                     | 9904                               | ---                                |
| CO <sub>2</sub>      | -393,520                     | 9364                               | ---                                |

Thus,

$$(0.7215)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (0.2535)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.4170)(0 + \bar{h}_{\text{O}_2} - 8682) \\ + (4.71)(0 + \bar{h}_{\text{N}_2} - 8669) = (1.2509)(0 + 11,711 - 8682) + (4.703)(11,640 - 8669)$$

$$\text{It yields } 0.7215\bar{h}_{\text{CO}_2} + 0.2535\bar{h}_{\text{H}_2\text{O}} + 0.4170\bar{h}_{\text{O}_2} + 4.71\bar{h}_{\text{N}_2} = 416,706 \text{ kJ}$$

The product temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $416,706 / (0.7215 + 0.2535 + 0.4170 + 4.71) = 68,290 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 2100 K for N<sub>2</sub>. Noting that the majority of the moles are N<sub>2</sub>,  $T_P$  will be close to 2100 K, but somewhat under it because of the higher specific heat of H<sub>2</sub>O.

At 2000 K:

$$0.7215\bar{h}_{\text{CO}_2} + 0.2535\bar{h}_{\text{H}_2\text{O}} + 0.4170\bar{h}_{\text{O}_2} + 4.71\bar{h}_{\text{N}_2} = (0.7215)(100,804) + (0.2535)(82,593) \\ + (0.4170)(67,881) + (4.71)(64,810) \\ = 427,229 \text{ kJ (Higher than 416,706 kJ)}$$

At 1980 K:

$$0.7215\bar{h}_{\text{CO}_2} + 0.2535\bar{h}_{\text{H}_2\text{O}} + 0.4170\bar{h}_{\text{O}_2} + 4.71\bar{h}_{\text{N}_2} = (0.7215)(99,606) + (0.2535)(81,573) \\ + (0.4170)(67,127) + (4.71)(64,090) \\ = 422,400 \text{ kJ (Higher than 416,706 kJ)}$$

By extrapolation,  $T_P = 1956 \text{ K} = 1683^\circ\text{C}$

**15-85** A certain coal is burned with 50 percent excess air adiabatically during a steady-flow combustion process. The combustion gases are expanded in an isentropic turbine. The work produced by this turbine is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 The effect of sulfur in the energy and entropy balances is negligible.

**Properties** The molar masses of C, O<sub>2</sub>, H<sub>2</sub>, S, and air are 12, 32, 2, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The balanced combustion equation from the previous problem is

The change of the entropy of this mixture during the expansion is given by

$$\Delta \bar{s} = \sum y \left( \bar{s}_2^o - \bar{s}_1^o - R \ln \frac{P_2}{P_1} \right)$$

Since there is no entropy change during an isentropic process, this equation becomes

$$\sum y (\bar{s}_2^o - \bar{s}_1^o) = R_u \ln \frac{P_2}{P_1} \sum y = (8.314 \text{ kJ/kmol} \cdot \text{K}) \ln \frac{140 \text{ kPa}}{1380 \text{ kPa}} (6.1038 \text{ kmol}) = -116.1 \text{ kJ/K}$$

Here, the total moles of the products are 6.1038 kmol. The exit temperature of the combustion gases may be determined by a trial-error method. The inlet temperature is 1956 K ( $\cong$  1960 K) from the previous problem. Guessing the exit temperature to be 1000 K gives (Tables A-18 through A-23)

$$\begin{aligned} \sum y (\bar{s}_2^o - \bar{s}_1^o) &= (0.7215)(269.215 - 307.992) + (0.2535)(232.597 - 263.542) \\ &\quad + (4.71)(228.057 - 251.242) + (0.417)(243.471 - 267.891) \\ &= -155.2 \text{ kJ/K} \end{aligned}$$

For the exit temperature of 1200 K,

$$\begin{aligned} \sum y (\bar{s}_2^o - \bar{s}_1^o) &= (0.7215)(297.307 - 307.992) + (0.2535)(240.333 - 263.542) \\ &\quad + (4.71)(234.115 - 251.242) + (0.417)(249.906 - 267.891) \\ &= -101.8 \text{ kJ/K} \end{aligned}$$

By interpolation,  $T_2 = 1146 \text{ K}$

The work produced during the isentropic expansion of combustion gases from 1956 K to 1146 K is (Tables A-18 through A-23)

$$\begin{aligned} \bar{w}_{\text{out}} &= \sum y (\bar{h}_1 - \bar{h}_2) = (0.7215)(98,160 - 50,819) + (0.2535)(80,352 - 42,037) \\ &\quad + (4.71)(63,236 - 34,961) + (0.417)(66,223 - 36,527) \\ &= 189,428 \text{ kJ/kmol fuel} \end{aligned}$$

The molar mass of the product gases is

$$M_m = \frac{m_m}{N_m} = \frac{(0.7215 \times 44 + 0.2535 \times 18 + 0.0018 \times 64 + 4.71 \times 28 + 0.4170 \times 32) \text{ kg}}{(0.7215 + 0.2535 + 0.0018 + 4.71 + 0.417) \text{ kmol}} = 29.76 \text{ kg/kmol}$$

The work produced per kg of the fuel is then

$$w_{\text{out}} = \frac{\bar{w}_{\text{out}}}{M_m} = \frac{189,428 \text{ kJ/kmol fuel}}{29.76 \text{ kg/kmol}} = \mathbf{6365 \text{ kJ/kg fuel}}$$

**15-86** Ethyl alcohol is burned with 200 percent excess air adiabatically in a constant volume container. The final pressure and temperature of product gases are to be determined.

**Assumptions** 1 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** The combustion equation is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$0.5 + 3a_{\text{th}} = 2 + 1.5 + 2a_{\text{th}} \longrightarrow a_{\text{th}} = 3$$

Substituting,

$\text{C}_2\text{H}_5\text{OH} + 9[\text{O}_2 + 3.76\text{N}_2] \longrightarrow 2\text{CO}_2 + 3\text{H}_2\text{O} + 33.84\text{N}_2 + 6\text{O}_2$  For this constant-volume process, the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $Q = W = 0$  reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ . It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - R_u T)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - R_u T)_R$$

From the tables,

| Substance                           | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol |
|-------------------------------------|------------------------------|------------------------------------|
| $\text{C}_2\text{H}_5\text{OH} (g)$ | -235,310                     | ---                                |
| $\text{O}_2$                        | 0                            | 8682                               |
| $\text{N}_2$                        | 0                            | 8669                               |
| $\text{H}_2\text{O} (g)$            | -241,820                     | 9904                               |
| $\text{CO}_2$                       | -393,520                     | 9364                               |

Thus,

$$\begin{aligned} & (2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_p) + (3)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_p) \\ & + (6)(0 + \bar{h}_{\text{O}_2} - 8682 - 8.314 \times T_p) + (33.84)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_p) \\ & = (1)(-235,310 - 8.314 \times 298) + (9)(0 - 8.314 \times 298) + (33.84)(-8.314 \times 298) \end{aligned}$$

It yields

$$2\bar{h}_{\text{CO}_2} + 3\bar{h}_{\text{H}_2\text{O}} + 6\bar{h}_{\text{O}_2} + 33.84\bar{h}_{\text{N}_2} - 372.8T_p = -343,927 + 1,906,391 = 1,562,464 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess may be obtained by assuming all the products are nitrogen and using nitrogen enthalpy in the above equation. That is,

$$44.84\bar{h}_{\text{N}_2} - 372.8T_p = 1,562,464 \text{ kJ}$$

An investigation of Table A-18 shows that this equation is satisfied at a temperature close to 1600 K but it will be somewhat under it because of the higher specific heat of H<sub>2</sub>O.

At 1500 K:

$$(2)(71,078) + (3)(57,999) + (6)(49,292) + (33.84)(47,073) - (372.8)(1500) = 1,645,655$$

(Higher than 1,562,464 kJ)

At 1400 K:

$$(2)(65,271) + (3)(53,351) + (6)(45,648) + (33.84)(43,605) - (372.8)(1400) = 1,518,156$$

(Lower than 1,562,464 kJ)

By interpolation,

$$T_P = \mathbf{1435\text{ K}}$$

The volume of reactants when 1 kmol of fuel is burned is

$$\mathcal{V} = \mathcal{V}_{\text{fuel}} + \mathcal{V}_{\text{air}} = (N_{\text{fuel}} + N_{\text{air}}) \frac{R_u T}{P} = (1 + 42.84) \text{ kmol} \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})}{100 \text{ kPa}} = 1086 \text{ m}^3$$

The final pressure is then

$$P = N_{\text{prod}} \frac{R_u T}{\mathcal{V}} = (44.84 \text{ kmol}) \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(1435 \text{ K})}{1086 \text{ m}^3} = \mathbf{493 \text{ kPa}}$$

**15-87** A mixture of hydrogen and the stoichiometric amount of air contained in a constant-volume tank is ignited. The final temperature in the tank is to be determined.

**Assumptions** **1** The tank is adiabatic. **2** Both the reactants and products are ideal gases. **3** There are no work interactions. **4** Combustion is complete.

**Analysis** The combustion equation of  $H_2$  with stoichiometric amount of air is

The final temperature in the tank is determined from the energy balance relation  $E_{in} - E_{out} = \Delta E_{system}$  for reacting closed systems under adiabatic conditions ( $Q = 0$ ) with no work interactions ( $W = 0$ ),

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ .

It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_P} - \bar{h}_{298\text{ K}} - R_u T)_P = \sum N_R (\bar{h}_f^\circ + R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

| Substance            | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol |
|----------------------|------------------------------|-------------------------------------|
| H <sub>2</sub>       | 0                            | 8468                                |
| O <sub>2</sub>       | 0                            | 8682                                |
| N <sub>2</sub>       | 0                            | 8669                                |
| H <sub>2</sub> O (g) | -241,820                     | 9904                                |

Thus,

$$(1)(-241,820 + \bar{h}_{H_2O} - 9904 - 8.314 \times T_P) + (1.88)(0 + \bar{h}_{N_2} - 8669 - 8.314 \times T_P) \\ = (1)(0 - 8.314 \times 298) + (0.5)(0 - 8.314 \times 298) + (1.88)(0 - 8.314 \times 298)$$

It yields  $\bar{h}_{H_2O} + 1.88\bar{h}_{N_2} - 23.94 \times T_P = 259,648 \text{ kJ}$

The temperature of the product gases is obtained from a trial and error solution,

At 3050 K:  $\bar{h}_{H_2O} + 1.88\bar{h}_{N_2} - 23.94 \times T_P = (1)(139,051) + (1.88)(103,260) - (23.94)(3050) \\ = 260,163 \text{ kJ (Higher than 259,648 kJ)}$

At 3000 K:  $\bar{h}_{H_2O} + 1.88\bar{h}_{N_2} - 23.94 \times T_P = (1)(136,264) + (1.88)(101,407) - (23.94)(3000) \\ = 255,089 \text{ kJ (Lower than 259,648 kJ)}$

By interpolation,  $T_P = 3045 \text{ K}$

**Entropy Change and Second Law Analysis of Reacting Systems**

**15-88C** Assuming the system exchanges heat with the surroundings at  $T_0$ , the increase-in-entropy principle can be expressed as

$$S_{\text{gen}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_0}$$

**15-89C** By subtracting  $R \ln(P/P_0)$  from the tabulated value at 1 atm. Here  $P$  is the actual pressure of the substance and  $P_0$  is the atmospheric pressure.

**15-90C** It represents the reversible work associated with the formation of that compound.

**15-91** Hydrogen is burned steadily with oxygen. The reversible work and exergy destruction (or irreversibility) are to be determined.

**Assumptions** **1** Combustion is complete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases. **4** Changes in kinetic and potential energies are negligible.

**Analysis** The combustion equation is

The  $\text{H}_2$ , the  $\text{O}_2$ , and the  $\text{H}_2\text{O}$  are at  $25^\circ\text{C}$  and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ = N_{\text{H}_2} \bar{g}_{f,\text{H}_2}^{\phi 0} + N_{\text{O}_2} \bar{g}_{f,\text{O}_2}^{\phi 0} - N_{\text{H}_2\text{O}} \bar{g}_{f,\text{H}_2\text{O}}^\circ = -N_{\text{H}_2\text{O}} \bar{g}_{f,\text{H}_2\text{O}}^\circ \\ &= -(1 \text{ kmol})(-237,180 \text{ kJ/kmol}) = \mathbf{237,180 \text{ kJ}} \quad (\text{per kmol of } \text{H}_2) \end{aligned}$$

since the  $g_f^\circ$  of stable elements at  $25^\circ\text{C}$  and 1 atm is zero. Therefore, 237,180 kJ of work could be done as 1 kmol of  $\text{H}_2$  is burned with 0.5 kmol of  $\text{O}_2$  at  $25^\circ\text{C}$  and 1 atm in an environment at the same state. The reversible work in this case represents the exergy of the reactants since the product (the  $\text{H}_2\text{O}$ ) is at the state of the surroundings.

This process involves no actual work. Therefore, the reversible work and exergy destruction are identical,

$$X_{\text{destruction}} = \mathbf{237,180 \text{ kJ}} \quad (\text{per kmol of } \text{H}_2)$$

We could also determine the reversible work without involving the Gibbs function,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - T_0 \bar{s})_P \\ &= \sum N_R (\bar{h}_f^\circ - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^\circ - T_0 \bar{s})_P \\ &= N_{\text{H}_2} (\bar{h}_f^\circ - T_0 \bar{s})_{\text{H}_2} + N_{\text{O}_2} (\bar{h}_f^\circ - T_0 \bar{s})_{\text{O}_2} - N_{\text{H}_2\text{O}} (\bar{h}_f^\circ - T_0 \bar{s})_{\text{H}_2\text{O}} \end{aligned}$$

Substituting,

$$W_{\text{rev}} = (1)(0 - 298 \times 130.58) + (0.5)(0 - 298 \times 205.03) - (1)(-285,830 - 298 \times 69.92) = 237,204 \text{ kJ}$$

which is almost identical to the result obtained before.

**15-92** Ethylene gas is burned steadily with 20 percent excess air. The temperature of products, the entropy generation, and the exergy destruction (or irreversibility) are to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** (a) The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol of  $\text{C}_2\text{H}_4$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1.2a_{\text{th}} = 2 + 1 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 3$$

Under steady-flow conditions, the exit temperature of the product gases can be determined from the steady-flow energy equation, which reduces to

$$\sum N_P(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R\bar{h}_{f,R}^\circ = (N\bar{h}_f^\circ)_{\text{C}_2\text{H}_4}$$

since all the reactants are at the standard reference state, and for  $\text{O}_2$  and  $\text{N}_2$ . From the tables,

| Substance                        | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol |
|----------------------------------|------------------------------|-------------------------------------|
| $\text{C}_2\text{H}_4(\text{g})$ | 52,280                       | ---                                 |
| $\text{O}_2$                     | 0                            | 8682                                |
| $\text{N}_2$                     | 0                            | 8669                                |
| $\text{H}_2\text{O}(\text{g})$   | -241,820                     | 9904                                |
| $\text{CO}_2$                    | -393,520                     | 9364                                |

Substituting,

$$(2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.6)(0 + \bar{h}_{\text{O}_2} - 8682) + (13.54)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(52,280)$$

or, 
$$2\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 0.6\bar{h}_{\text{O}_2} + 13.54\bar{h}_{\text{N}_2} = 1,484,083 \text{ kJ}$$

By trial and error,

$$T_P = 2269.6 \text{ K}$$

(b) The entropy generation during this adiabatic process is determined from

$$S_{\text{gen}} = S_P - S_R = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R$$

The  $\text{C}_2\text{H}_4$  is at  $25^\circ\text{C}$  and 1 atm, and thus its absolute entropy is  $219.83 \text{ kJ/kmol}\cdot\text{K}$  (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                              | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$ |
|------------------------------|-------|--------|-----------------------------------|--------------------|-----------------|
| $\text{C}_2\text{H}_4$       | 1     | 1.00   | 219.83                            | ---                | 219.83          |
| $\text{O}_2$                 | 3.6   | 0.21   | 205.14                            | -12.98             | 784.87          |
| $\text{N}_2$                 | 13.54 | 0.79   | 191.61                            | -1.96              | 2620.94         |
| $S_R = 3625.64 \text{ kJ/K}$ |       |        |                                   |                    |                 |
| $\text{CO}_2$                | 2     | 0.1103 | 316.881                           | -18.329            | 670.42          |
| $\text{H}_2\text{O}$         | 2     | 0.1103 | 271.134                           | -18.329            | 578.93          |
| $\text{O}_2$                 | 0.6   | 0.0331 | 273.467                           | -28.336            | 181.08          |
| $\text{N}_2$                 | 13.54 | 0.7464 | 256.541                           | -2.432             | 3506.49         |
| $S_P = 4936.92 \text{ kJ/K}$ |       |        |                                   |                    |                 |

Thus,

$$S_{\text{gen}} = S_P - S_R = 4936.92 - 3625.64 = \mathbf{1311.28 \text{ kJ/kmol} \cdot \text{K}}$$

and

$$(c) \quad X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(1311.28 \text{ kJ/kmol} \cdot \text{K C}_2\text{H}_4) = \mathbf{390,760 \text{ kJ}} \text{ (per kmol C}_2\text{H}_4)$$

**15-93** Liquid octane is burned steadily with 50 percent excess air. The heat transfer rate from the combustion chamber, the entropy generation rate, and the reversible work and exergy destruction rate are to be determined.

**Assumptions** **1** Combustion is complete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases. **4** Changes in kinetic and potential energies are negligible.

**Analysis** (a) The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol  $\text{C}_8\text{H}_{18}$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1.5a_{\text{th}} = 8 + 4.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Thus,

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at  $25^\circ\text{C}$ . Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                       | $\bar{h}_f^\circ$<br>kJ/kmol |
|---------------------------------|------------------------------|
| $\text{C}_8\text{H}_{18}(\ell)$ | -249,950                     |
| $\text{O}_2$                    | 0                            |
| $\text{N}_2$                    | 0                            |
| $\text{H}_2\text{O}(l)$         | -285,830                     |
| $\text{CO}_2$                   | -393,520                     |

Substituting,

$$-Q_{\text{out}} = (8)(-393,520) + (9)(-285,830) + 0 + 0 - (1)(-249,950) - 0 - 0 = -5,470,680 \text{ kJ/kmol of } \text{C}_8\text{H}_{18}$$

or

$$Q_{\text{out}} = 5,470,680 \text{ kJ/kmol of } \text{C}_8\text{H}_{18}$$

The  $\text{C}_8\text{H}_{18}$  is burned at a rate of 0.25 kg/min or

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.25 \text{ kg/min}}{[(8)(12) + (18)(1)] \text{ kg/kmol}} = 2.193 \times 10^{-3} \text{ kmol/min}$$

Thus,

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = (2.193 \times 10^{-3} \text{ kmol/min})(5,470,680 \text{ kJ/kmol}) = \mathbf{11,997 \text{ kJ/min}}$$

The heat transfer for this process is also equivalent to the enthalpy of combustion of liquid  $C_8H_{18}$ , which could easily be determined from Table A-27 to be  $\bar{h}_C = 5,470,740$  kJ/kmol  $C_8H_{18}$ .

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} \longrightarrow S_{\text{gen}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The  $C_8H_{18}$  is at  $25^\circ\text{C}$  and 1 atm, and thus its absolute entropy is  $\bar{s}_{C_8H_{18}} = 360.79$  kJ/kmol·K (Table A-26).

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                        | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$ |
|------------------------|-------|--------|-----------------------------------|--------------------|-----------------|
| $C_8H_{18}$            | 1     | 1.00   | 360.79                            | ---                | 360.79          |
| $O_2$                  | 18.75 | 0.21   | 205.14                            | -12.98             | 4089.75         |
| $N_2$                  | 70.50 | 0.79   | 191.61                            | -1.96              | 13646.69        |
| $S_R = 18,097.23$ kJ/K |       |        |                                   |                    |                 |
| $CO_2$                 | 8     | 0.0944 | 213.80                            | -19.62             | 1867.3          |
| $H_2O (\ell)$          | 9     | ---    | 69.92                             | ---                | 629.3           |
| $O_2$                  | 6.25  | 0.0737 | 205.04                            | -21.68             | 1417.6          |
| $N_2$                  | 70.50 | 0.8319 | 191.61                            | -1.53              | 13,616.3        |
| $S_P = 17,531$ kJ/K    |       |        |                                   |                    |                 |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{surr}}}{T_{\text{surr}}} = 17,531 - 18,097 + \frac{5,470,523 \text{ kJ}}{298 \text{ K}} = 17,798 \text{ kJ/kmol} \cdot \text{K}$$

and

$$\dot{S}_{\text{gen}} = \dot{N} S_{\text{gen}} = (2.193 \times 10^{-3} \text{ kmol/min}) (17,798 \text{ kJ/kmol} \cdot \text{K}) = \mathbf{39.03 \text{ kJ/min} \cdot \text{K}}$$

(c) The exergy destruction rate associated with this process is determined from

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K}) (39.03 \text{ kJ/min} \cdot \text{K}) = 11,632 \text{ kJ/min} = \mathbf{193.9 \text{ kW}}$$

**15-94E** Benzene gas is burned steadily with 95 percent theoretical air. The heat transfer rate from the combustion chamber and the exergy destruction are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and the combustion gases are ideal gases. 3 Changes in kinetic and potential energies are negligible.

**Analysis** (a) The fuel is burned with insufficient amount of air, and thus the products will contain some CO as well as CO<sub>2</sub>, H<sub>2</sub>O, and N<sub>2</sub>. The theoretical combustion equation of C<sub>6</sub>H<sub>6</sub> is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the O<sub>2</sub> balance,

$$a_{\text{th}} = 6 + 1.5 = 7.5$$

Then the actual combustion equation can be written as

The value of  $x$  is determined from an O<sub>2</sub> balance,

$$(0.95)(7.5) = x + (6-x)/2 + 1.5 \longrightarrow x = 5.25$$

Thus,

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}$$

since all of the reactants are at 77°F. Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ .

From the tables,

| Substance                         | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{537\text{ R}}$<br>Btu/lbmol | $\bar{h}_{1500\text{ R}}$<br>Btu/lbmol |
|-----------------------------------|--------------------------------|---------------------------------------|----------------------------------------|
| C <sub>6</sub> H <sub>6</sub> (g) | 35,680                         | ---                                   | ---                                    |
| O <sub>2</sub>                    | 0                              | 3725.1                                | 11,017.1                               |
| N <sub>2</sub>                    | 0                              | 3729.5                                | 10,648.0                               |
| H <sub>2</sub> O (g)              | -104,040                       | 4258.0                                | 12,551.4                               |
| CO                                | -47,540                        | 3725.1                                | 10,711.1                               |
| CO <sub>2</sub>                   | -169,300                       | 4027.5                                | 14,576.0                               |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (5.25)(-169,300 + 14,576 - 4027.5) + (0.75)(-47,540 + 10,711.1 - 3725.1) \\ &\quad + (3)(-104,040 + 12,551.4 - 4258) + (26.79)(0 + 10,648 - 3729.5) - (1)(35,680) - 0 - 0 \\ &= -1,001,434 \text{ Btu/lbmol of C}_6\text{H}_6 \end{aligned}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The  $\text{C}_6\text{H}_6$  is at  $77^\circ\text{F}$  and 1 atm, and thus its absolute entropy is  $\bar{s}_{\text{C}_6\text{H}_6} = 64.34 \text{ Btu/lbmol}\cdot\text{R}$  (Table A-26E).

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                               | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$ |
|-------------------------------|-------|--------|-----------------------------------|--------------------|-----------------|
| $\text{C}_6\text{H}_6$        | 1     | 1.00   | 64.34                             | ---                | 64.34           |
| $\text{O}_2$                  | 7.125 | 0.21   | 49.00                             | -3.10              | 371.21          |
| $\text{N}_2$                  | 26.79 | 0.79   | 45.77                             | -0.47              | 1238.77         |
| $S_R = 1674.32 \text{ Btu/R}$ |       |        |                                   |                    |                 |
| $\text{CO}_2$                 | 5.25  | 0.1467 | 61.974                            | -3.812             | 345.38          |
| $\text{CO}$                   | 0.75  | 0.0210 | 54.665                            | -7.672             | 46.75           |
| $\text{H}_2\text{O} (g)$      | 3     | 0.0838 | 53.808                            | -4.924             | 176.20          |
| $\text{N}_2$                  | 26.79 | 0.7485 | 53.071                            | -0.575             | 1437.18         |
| $S_P = 2005.51 \text{ Btu/R}$ |       |        |                                   |                    |                 |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 2005.51 - 1674.32 + \frac{+1,001,434}{537} = 2196.1 \text{ Btu/R}$$

Then the exergy destroyed is determined from

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (537 \text{ R})(2196.1 \text{ Btu/lbmol}\cdot\text{R}) = \mathbf{1,179,306 \text{ Btu/R}} \text{ (per lbmol } \text{C}_6\text{H}_6 \text{)}$$

**15-95 [Also solved by EES on enclosed CD]** Liquid propane is burned steadily with 150 percent excess air. The mass flow rate of air, the heat transfer rate from the combustion chamber, and the rate of entropy generation are to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Properties** The molar masses of  $C_3H_8$  and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The fuel is burned completely with the excess air, and thus the products will contain only  $CO_2$ ,  $H_2O$ ,  $N_2$ , and some free  $O_2$ . Considering 1 kmol of  $C_3H_8$ , the combustion equation can be written as

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$2.5a_{th} = 3 + 2 + 1.5a_{th} \longrightarrow a_{th} = 5$$

Substituting,

The air-fuel ratio for this combustion process is

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = 39.2 \text{ kg air/kg fuel}$$

Thus,

$$\dot{m}_{air} = (AF)(\dot{m}_{fuel}) = (39.2 \text{ kg air/kg fuel})(0.4 \text{ kg fuel/min}) = \mathbf{15.7 \text{ kg air/min}}$$

(b) Under steady-flow conditions the energy balance  $E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables, (The  $\bar{h}_f^\circ$  of liquid propane is obtained by adding the  $h_{fg}$  at  $25^\circ\text{C}$  to  $\bar{h}_f^\circ$  of gaseous propane).

| Substance      | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{285 \text{ K}}$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{1200 \text{ K}}$<br>kJ/kmol |
|----------------|------------------------------|--------------------------------------|--------------------------------------|---------------------------------------|
| $C_3H_8(\ell)$ | -118,910                     | ---                                  | ---                                  | ---                                   |
| $O_2$          | 0                            | 8296.5                               | 8682                                 | 38,447                                |
| $N_2$          | 0                            | 8286.5                               | 8669                                 | 36,777                                |
| $H_2O(g)$      | -241,820                     | ---                                  | 9904                                 | 44,380                                |
| $CO_2$         | -393,520                     | ---                                  | 9364                                 | 53,848                                |

Thus,

$$\begin{aligned} -Q_{out} &= (3)(-393,520 + 53,848 - 9364) + (4)(-241,820 + 44,380 - 9904) \\ &\quad + (7.5)(0 + 38,447 - 8682) + (47)(0 + 36,777 - 8669) - (1)(-118,910 + h_{298} - h_{298}) \\ &\quad - (12.5)(0 + 8296.5 - 8682) - (47)(0 + 8286.5 - 8669) \\ &= -190,464 \text{ kJ/kmol of } C_3H_8 \end{aligned}$$

Thus 190,464 kJ of heat is transferred from the combustion chamber for each kmol (44 kg) of propane. This corresponds to  $190,464/44 = 4328.7$  kJ of heat transfer per kg of propane. Then the rate of heat transfer for a mass flow rate of 0.4 kg/min for the propane becomes

$$\dot{Q}_{\text{out}} = \dot{m}q_{\text{out}} = (0.4 \text{ kg/min})(4328.7 \text{ kJ/kg}) = \mathbf{1732 \text{ kJ/min}}$$

(c) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The  $\text{C}_3\text{H}_8$  is at  $25^\circ\text{C}$  and 1 atm, and thus its absolute entropy for the gas phase is  $\bar{s}_{\text{C}_3\text{H}_8} = 269.91 \text{ kJ/kmol}\cdot\text{K}$  (Table A-26). Then the entropy of  $\text{C}_3\text{H}_8(\ell)$  is obtained from

$$s_{\text{C}_3\text{H}_8}(\ell) \cong s_{\text{C}_3\text{H}_8}(\text{g}) - s_{fg} = s_{\text{C}_3\text{H}_8}(\text{g}) - \frac{\bar{h}_{fg}}{T} = 269.91 - \frac{15,060}{298.15} = 219.4 \text{ kJ/kmol}\cdot\text{K}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                                | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$ |
|--------------------------------|-------|--------|-----------------------------------|--------------------|-----------------|
| $\text{C}_3\text{H}_8$         | 1     | ---    | 219.40                            | ---                | 219.40          |
| $\text{O}_2$                   | 12.5  | 0.21   | 203.70                            | -12.98             | 2708.50         |
| $\text{N}_2$                   | 47    | 0.79   | 190.18                            | -1.96              | 9030.58         |
| $S_R = 11,958.48 \text{ kJ/K}$ |       |        |                                   |                    |                 |
| $\text{CO}_2$                  | 3     | 0.0488 | 279.307                           | -25.112            | 913.26          |
| $\text{H}_2\text{O}(g)$        | 4     | 0.0650 | 240.333                           | -22.720            | 1052.21         |
| $\text{O}_2$                   | 7.5   | 0.1220 | 249.906                           | -17.494            | 2005.50         |
| $\text{N}_2$                   | 47    | 0.7642 | 234.115                           | -2.236             | 11108.50        |
| $S_P = 15,079.47 \text{ kJ/K}$ |       |        |                                   |                    |                 |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 15,079.47 - 11,958.48 + \frac{190,464}{298} = 3760.1 \text{ kJ/K (per kmol } \text{C}_3\text{H}_8 \text{)}$$

Then the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = (\dot{N})(S_{\text{gen}}) = \left( \frac{0.4}{44} \text{ kmol/min} \right) (3760.1 \text{ kJ/kmol}\cdot\text{K}) = \mathbf{34.2 \text{ kJ/min}\cdot\text{K}}$$

**15-96 EES** Problem 15-95 is reconsidered. The effect of the surroundings temperature on the rate of exergy destruction is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

**15-97** Liquid octane is burned steadily with 200 percent excess air in a automobile engine. The maximum amount of work that can be produced by this engine is to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol  $\text{C}_8\text{H}_{18}$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$3a_{\text{th}} = 8 + 4.5 + 2a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Thus,

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                       | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{350\text{K}}$<br>kJ/kmol |
|---------------------------------|------------------------------|------------------------------------|------------------------------------|
| $\text{C}_8\text{H}_{18}(\ell)$ | -249,950                     | ---                                | ---                                |
| $\text{O}_2$                    | 0                            | 8682                               | 10,213                             |
| $\text{N}_2$                    | 0                            | 8669                               | 10,180                             |
| $\text{H}_2\text{O}(g)$         | -241,820                     | 9904                               | 11,652                             |
| $\text{CO}_2$                   | -393,520                     | 9364                               | 11,351                             |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (8)(-393,520 + 11,351 - 9364) + (9)(-241,820 + 11,652 - 9904) \\ &\quad + (25)(0 + 10,213 - 8682) + (141)(0 + 10,180 - 8669) - (1)(-249,950) \\ &= -4,791,636 \text{ kJ/kmol of } \text{C}_8\text{H}_{18} \end{aligned}$$

The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

|             | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$             |
|-------------|-------|--------|-----------------------------------|--------------------|-----------------------------|
| $C_8H_{18}$ | 1     | ---    | 466.73                            | ---                | 466.73                      |
| $O_2$       | 37.5  | 0.21   | 205.04                            | -12.98             | 8175.75                     |
| $N_2$       | 141   | 0.79   | 191.61                            | -1.960             | 27,293.37                   |
|             |       |        |                                   |                    | $S_R = 35,936 \text{ kJ/K}$ |
| $CO_2$      | 8     | 0.0437 | 219.831                           | -26.03             | 1966.89                     |
| $H_2O(g)$   | 9     | 0.0492 | 194.125                           | -25.04             | 1972.49                     |
| $O_2$       | 25    | 0.1366 | 209.765                           | -16.55             | 5657.88                     |
| $N_2$       | 141   | 0.7705 | 196.173                           | -2.17              | 27,966.36                   |
|             |       |        |                                   |                    | $S_P = 37,565 \text{ kJ/K}$ |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 37,565 - 35,936 + \frac{4,791,636}{298} = 17,708 \text{ kJ/K (per kmol } C_8H_{18} \text{)}$$

The maximum work is equal to the exergy destruction

$$W_{\text{max}} = X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(17,708 \text{ kJ/K}) = 5,276,984 \text{ kJ/K (per kmol } C_8H_{18} \text{)}$$

Per unit mass basis,

$$W_{\text{max}} = \frac{5,276,984 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{46,290 \text{ kJ/kg fuel}}$$

**15-98** Methane is burned steadily with 200 percent excess air in a automobile engine. The maximum amount of work that can be produced by this engine is to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol  $\text{CH}_4$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$3a_{\text{th}} = 1 + 1 + 2a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

Thus,

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{350\text{K}}$<br>kJ/kmol |
|--------------------------|------------------------------|------------------------------------|------------------------------------|
| $\text{CH}_4$            | -74,850                      | ---                                | ---                                |
| $\text{O}_2$             | 0                            | 8682                               | 10,213                             |
| $\text{N}_2$             | 0                            | 8669                               | 10,180                             |
| $\text{H}_2\text{O} (g)$ | -241,820                     | 9904                               | 11,652                             |
| $\text{CO}_2$            | -393,520                     | 9364                               | 11,351                             |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 11,351 - 9364) + (2)(-241,820 + 11,652 - 9904) \\ &\quad + (4)(0 + 10,213 - 8682) + (22.56)(0 + 10,180 - 8669) - (1)(-74,850) \\ &= -756,615 \text{ kJ/kmol of } \text{CH}_4 \end{aligned}$$

The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

|                               | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$              |
|-------------------------------|-------|--------|-----------------------------------|--------------------|------------------------------|
| CH <sub>4</sub>               | 1     | ---    | 186.16                            | ---                | 186.16                       |
| O <sub>2</sub>                | 6     | 0.21   | 205.04                            | -12.98             | 1308.12                      |
| N <sub>2</sub>                | 22.56 | 0.79   | 191.61                            | -1.960             | 4366.94                      |
|                               |       |        |                                   |                    | $S_R = 5861.22 \text{ kJ/K}$ |
| CO <sub>2</sub>               | 1     | 0.0338 | 219.831                           | -28.16             | 247.99                       |
| H <sub>2</sub> O ( <i>g</i> ) | 2     | 0.0677 | 194.125                           | -22.39             | 433.03                       |
| O <sub>2</sub>                | 4     | 0.1353 | 209.765                           | -16.63             | 905.58                       |
| N <sub>2</sub>                | 22.56 | 0.7632 | 196.173                           | -2.25              | 4476.42                      |
|                               |       |        |                                   |                    | $S_P = 6063.02 \text{ kJ/K}$ |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 6063.02 - 5861.22 + \frac{756,615}{298} = 2741 \text{ kJ/K (per kmol CH}_4\text{)}$$

The maximum work is equal to the exergy destruction

$$W_{\text{max}} = X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(2741 \text{ kJ/K}) = 816,818 \text{ kJ/K (per kmol CH}_4\text{)}$$

Per unit mass basis,

$$W_{\text{max}} = \frac{816,818 \text{ kJ/K} \cdot \text{kmol}}{16 \text{ kg/kmol}} = \mathbf{51,050 \text{ kJ/kg fuel}}$$

**15-99** Liquid octane is burned steadily with 30 percent excess air. The entropy generation and exergy destruction per unit mass of the fuel are to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Properties** The molar masses of  $C_8H_{18}$  and air are 114 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $CO_2$ ,  $H_2O$ ,  $N_2$ , and some free  $O_2$ . Considering 1 kmol  $C_8H_{18}$ , the combustion equation can be written as

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$1.3a_{th} = 8 + 4.5 + 0.3a_{th} \longrightarrow a_{th} = 12.5$$

Thus,

(b) Under steady-flow conditions the energy balance  $E_{in} - E_{out} = \Delta E_{system}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{out} = \sum N_P(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance         | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298K}$<br>kJ/kmol | $\bar{h}_{600K}$<br>kJ/kmol | $\bar{h}_{1500K}$<br>kJ/kmol |

| $C_8H_{18}(\ell)$ | -249,950                     | ---                         | ---                         | ---                          |
| $O_2$             | 0                            | 8682                        | 17,929                      | 49,292                       |
| $N_2$             | 0                            | 8669                        | 17,563                      | 47,073                       |
| $H_2O(g)$         | -241,820                     | 9904                        | ---                         | 57,999                       |
| $CO_2$            | -393,520                     | 9364                        | ---                         | 71,078                       |

Thus,

$$\begin{aligned} -Q_{out} &= (8)(-393,520 + 71,078 - 9364) + (9)(-241,820 + 57,999 - 9904) \\ &\quad + (3.75)(0 + 49,292 - 8682) + (61.1)(0 + 47,073 - 8669) - (1)(-249,950) \\ &\quad - (16.25)(0 + 17,929 - 8682) - (61.1)(0 + 17,563 - 8669) \\ &= -2,342,938 \text{ kJ/kmol of } C_8H_{18} \end{aligned}$$

The entropy generation during this process is determined from

$$S_{gen} = S_P - S_R + \frac{Q_{out}}{T_{surr}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{out}}{T_{surr}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of  $P_m = 600 \text{ kPa}$  ( $=600/101.325=5.92 \text{ atm}$ ), but the entropies are to be calculated at

the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                           | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$                |
|---------------------------|-------|--------|-----------------------------------|--------------------|--------------------------------|
| $\text{C}_8\text{H}_{18}$ | 1     | ---    | 466.73                            | 14.79              | 451.94                         |
| $\text{O}_2$              | 16.25 | 0.21   | 226.35                            | 1.81               | 3648.78                        |
| $\text{N}_2$              | 61.1  | 0.79   | 212.07                            | 12.83              | 12,173.56                      |
|                           |       |        |                                   |                    | $S_R = 16,274.28 \text{ kJ/K}$ |
| $\text{CO}_2$             | 8     | 0.0977 | 292.11                            | -4.552             | 2373.30                        |
| $\text{H}_2\text{O} (g)$  | 9     | 0.1100 | 250.45                            | -3.566             | 2286.14                        |
| $\text{O}_2$              | 3.75  | 0.0458 | 257.97                            | -10.85             | 1008.08                        |
| $\text{N}_2$              | 61.1  | 0.7465 | 241.77                            | 12.35              | 14,017.56                      |
|                           |       |        |                                   |                    | $S_P = 19,685.08 \text{ kJ/K}$ |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 19,685.08 - 16,274.28 + \frac{2,342,938}{298} = 11,273 \text{ kJ/K (per kmol C}_8\text{H}_{18}\text{)}$$

The exergy destruction is

$$X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(11,273 \text{ kJ/K}) = 3,359,354 \text{ kJ/K (per kmol C}_8\text{H}_{18}\text{)}$$

The entropy generation and exergy destruction per unit mass of the fuel are

$$S_{\text{gen}} = \frac{\bar{S}_{\text{gen}}}{M_{\text{fuel}}} = \frac{11,273 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{98.89 \text{ kJ/K} \cdot \text{kg C}_3\text{H}_8$$

$$X_{\text{dest}} = \frac{\bar{X}_{\text{dest}}}{M_{\text{fuel}}} = \frac{3,359,354 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{29,470 \text{ kJ/kg C}_3\text{H}_8}$$

## Review Problems

**15-100** A sample of a certain fluid is burned in a bomb calorimeter. The heating value of the fuel is to be determined.

**Properties** The specific heat of water is  $4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$  (Table A-3).

**Analysis** We take the water as the system, which is a closed system, for which the energy balance on the system  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  with  $W = 0$  can be written as

$$Q_{\text{in}} = \Delta U$$

or

$$\begin{aligned} Q_{\text{in}} &= mc\Delta T \\ &= (2 \text{ kg})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(2.5^\circ\text{C}) \\ &= 20.90 \text{ kJ (per gram of fuel)} \end{aligned}$$

Therefore, heat transfer per kg of the fuel would be **20,900 kJ/kg fuel**. Disregarding the slight energy stored in the gases of the combustion chamber, this value corresponds to the heating value of the fuel.

**15-101E** Hydrogen is burned with 100 percent excess air. The AF ratio and the volume flow rate of air are to be determined.

**Assumptions** 1 Combustion is complete. 2 Air and the combustion gases are ideal gases.

**Properties** The molar masses of  $H_2$  and air are 2 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The combustion is complete, and thus products will contain only  $H_2O$ ,  $O_2$  and  $N_2$ . The moisture in the air does not react with anything; it simply shows up as additional  $H_2O$  in the products. Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. The combustion equation in this case can be written as

where  $a_{th}$  is the stoichiometric coefficient for air. It is determined from

$$O_2 \text{ balance: } 2a_{th} = 0.5 + a_{th} \longrightarrow a_{th} = 0.5$$

$$\text{Substituting, } H_2 + (O_2 + 3.76N_2) \longrightarrow H_2O + 0.5O_2 + 3.76N_2$$

Therefore, 4.76 lbmol of dry air will be used per kmol of the fuel. The partial pressure of the water vapor present in the incoming air is

$$P_{v,in} = \phi_{air} P_{sat@90^\circ F} = (0.60)(0.69904 \text{ psi}) = 0.419 \text{ psia}$$

The number of moles of the moisture that accompanies 4.76 lbmol of incoming dry air ( $N_{v,in}$ ) is determined to be

$$N_{v,in} = \left( \frac{P_{v,in}}{P_{total}} \right) N_{total} = \left( \frac{0.419 \text{ psia}}{14.5 \text{ psia}} \right) (4.76 + N_{v,in}) \longrightarrow N_{v,in} = 0.142 \text{ lbmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.142 lbmol of  $H_2O$  to both sides of the equation,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(4.76 \text{ lbmol})(29 \text{ lbm/lbmol}) + (0.142 \text{ lbmol})(18 \text{ lbm/lbmol})}{(1 \text{ lbmol})(2 \text{ lbm/lbmol})} = \mathbf{70.3 \text{ lbm air/lbm fuel}}$$

(b) The mass flow rate of  $H_2$  is given to be 10 lbm/h. Since we need 70.3 lbm air per lbm of  $H_2$ , the required mass flow rate of air is

$$\dot{m}_{air} = (AF)(\dot{m}_{fuel}) = (70.3)(25 \text{ lbm/h}) = 1758 \text{ lbm/h}$$

The mole fractions of water vapor and the dry air in the incoming air are

$$y_{H_2O} = \frac{N_{H_2O}}{N_{total}} = \frac{0.142}{4.76 + 0.142} = 0.029 \quad \text{and} \quad y_{dryair} = 1 - 0.029 = 0.971$$

Thus,

$$M = (yM)_{H_2O} + (yM)_{dryair} = (0.029)(18) + (0.971)(29) = 28.7 \text{ lbm/lbmol}$$

$$\nu = \frac{RT}{P} = \frac{(10.73/28.7 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(550 \text{ R})}{14.5 \text{ psia}} = 14.18 \text{ ft}^3/\text{lbm}$$

$$\dot{V} = \dot{m}\nu = (1758 \text{ lbm/h})(14.18 \text{ ft}^3/\text{lbm}) = \mathbf{24,928 \text{ ft}^3/\text{h}}$$

**15-102** A gaseous fuel with a known composition is burned with dry air, and the volumetric analysis of products gases is determined. The AF ratio, the percent theoretical air used, and the volume flow rate of air are to be determined.

**Assumptions** 1 Combustion is complete. 2 Air and the combustion gases are ideal gases.

**Properties** The molar masses of C, H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, and air are 12, 2, 28, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** Considering 100 kmol of dry products, the combustion equation can be written as

The unknown coefficients  $x$ ,  $a$ , and  $b$  are determined from mass balances,

$$\text{C: } 0.80x = 3.36 + 0.09 \longrightarrow x = 4.31$$

$$\text{H: } 3.2x = 2b \longrightarrow b = 6.90$$

$$\text{N}_2: 0.15x + 3.76a = 81.64 \longrightarrow a = 21.54$$

$$\left[ \text{Check O}_2: 0.05x + a = 3.36 + 0.045 + 14.91 + b/2 \longrightarrow a = 21.54 \right]$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 4.31,

(a) The air-fuel ratio is determined from its definition,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(5.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{0.8 \times 16 + 0.15 \times 28 + 0.05 \times 32} = \mathbf{37.1 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2: 0.05 + a_{\text{th}} = 0.8 + 0.8 \longrightarrow a_{\text{th}} = 1.55$$

$$\text{Then, Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(5.0)(4.76) \text{ kmol}}{(1.55)(4.76) \text{ kmol}} = \mathbf{323\%}$$

(c) The specific volume, mass flow rate, and the volume flow rate of air at the inlet conditions are

$$\begin{aligned} \nu &= \frac{RT}{P} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{100 \text{ kPa}} = 0.855 \text{ m}^3/\text{kg} \\ \dot{m}_{\text{air}} &= (\text{AF})\dot{m}_{\text{fuel}} = (37.1 \text{ kg air/kg fuel})(1.4 \text{ kg fuel/min}) = 51.94 \text{ m}^3/\text{min} \\ \dot{V}_{\text{air}} &= (\dot{m}\nu)_{\text{air}} = (51.94 \text{ kg/min})(0.855 \text{ m}^3/\text{kg}) = \mathbf{44.4 \text{ m}^3/\text{min}} \end{aligned}$$

**15-103** Propane is burned with stoichiometric amount of oxygen. The mass fractions of each of the products and the mass of water in the products per unit mass of fuel burned are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$ , and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation in this case is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (3 \text{ kmol})(44 \text{ kg/kmol}) = 132 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (4 \text{ kmol})(18 \text{ kg/kmol}) = 72 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} = 132 + 72 = 204 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{132 \text{ kg}}{204 \text{ kg}} = \mathbf{0.6471}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{72 \text{ kg}}{204 \text{ kg}} = \mathbf{0.3529}$$

The mass of water in the products per unit mass of fuel burned is determined from

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_3\text{H}_8}} = \frac{72 \text{ kg}}{44 \text{ kg}} = \mathbf{1.64 \text{ kg H}_2\text{O/kg C}_3\text{H}_8}$$

**15-104** A coal from Utah is burned with 20% excess air. The mass of water in the products per unit mass of coal burned and the dew-point temperature of the water vapor in the products are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{SO}_2$ ,  $\text{O}_2$ , and  $\text{N}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{O}_2$ ,  $\text{H}_2$ , S, and  $\text{N}_2$  are 12, 32, 2, 32, and 28 lbm/lbmol, respectively (Table A-1E).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$\begin{aligned} \text{mf}_C &= \frac{m_C}{m_{\text{total}}} = \frac{61.40 \text{ lbm}}{(100 - 5.00) \text{ lbm}} = \frac{61.40 \text{ lbm}}{95.00 \text{ lbm}} = 0.6463 \\ \text{mf}_{\text{H}_2} &= \frac{m_{\text{H}_2}}{m_{\text{total}}} = \frac{5.79 \text{ lbm}}{95.00 \text{ lbm}} = 0.06095 \\ \text{mf}_{\text{O}_2} &= \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{25.31 \text{ lbm}}{95.00 \text{ lbm}} = 0.2664 \\ \text{mf}_{\text{N}_2} &= \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1.09 \text{ lbm}}{95.00 \text{ lbm}} = 0.01147 \\ \text{mf}_S &= \frac{m_S}{m_{\text{total}}} = \frac{1.41 \text{ lbm}}{95.00 \text{ lbm}} = 0.01484 \end{aligned}$$

|                     |
|---------------------|
| 61.40% C            |
| 5.79% $\text{H}_2$  |
| 25.31% $\text{O}_2$ |
| 1.09% $\text{N}_2$  |
| 1.41% S             |
| 5.00% ash           |
| (by mass)           |

We now consider 100 lbm of this mixture. Then the mole numbers of each component are

$$\begin{aligned} N_C &= \frac{m_C}{M_C} = \frac{64.63 \text{ lbm}}{12 \text{ lbm/lbmol}} = 5.386 \text{ lbmol} \\ N_{\text{H}_2} &= \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{6.095 \text{ lbm}}{2 \text{ lbm/lbmol}} = 3.048 \text{ lbmol} \\ N_{\text{O}_2} &= \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{26.64 \text{ lbm}}{32 \text{ lbm/lbmol}} = 0.8325 \text{ lbmol} \\ N_{\text{N}_2} &= \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{1.147 \text{ lbm}}{28 \text{ lbm/lbmol}} = 0.04096 \text{ lbmol} \\ N_S &= \frac{m_S}{M_S} = \frac{1.484 \text{ lbm}}{32 \text{ lbm/lbmol}} = 0.04638 \text{ lbmol} \end{aligned}$$

The mole number of the mixture and the mole fractions are

$$N_m = 5.386 + 3.048 + 0.8325 + 0.04096 + 0.04638 = 9.354 \text{ lbmol}$$

$$\begin{aligned} y_C &= \frac{N_C}{N_m} = \frac{5.386 \text{ lbmol}}{9.354 \text{ lbmol}} = 0.5758 \\ y_{\text{H}_2} &= \frac{N_{\text{H}_2}}{N_m} = \frac{3.048 \text{ lbmol}}{9.354 \text{ lbmol}} = 0.3258 \\ y_{\text{O}_2} &= \frac{N_{\text{O}_2}}{N_m} = \frac{0.8325 \text{ lbmol}}{9.354 \text{ lbmol}} = 0.0890 \\ y_{\text{N}_2} &= \frac{N_{\text{N}_2}}{N_m} = \frac{0.04096 \text{ lbmol}}{9.354 \text{ lbmol}} = 0.00438 \\ y_S &= \frac{N_S}{N_m} = \frac{0.04638 \text{ lbmol}}{9.354 \text{ lbmol}} = 0.00496 \end{aligned}$$

Then, the combustion equation in this case may be written as

According to the oxygen balance,

$$\text{O}_2 \text{ balance: } 0.0890 + 1.2a_{\text{th}} = 0.5758 + 0.5 \times 0.3258 + 0.00496 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 0.6547$$

Substituting,

The mass of water in the products per unit mass of fuel burned is determined from

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{coal}}} = \frac{(0.3258 \times 18) \text{ lbm}}{(0.5758 \times 12 + 0.3258 \times 2 + 0.0890 \times 32 + 0.00438 \times 28 + 0.00496 \times 32) \text{ lbm}} \\ = \frac{5.864 \text{ kg}}{10.69 \text{ kg}} = \mathbf{0.5486 \text{ lbm H}_2\text{O/lbm coal}}$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left( \frac{0.3258 \text{ lbmol}}{(0.5758 + 0.3258 + 0.00496 + 0.1309 + 2.954) \text{ lbmol}} \right) (14.696 \text{ psia}) = 1.20 \text{ psia}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@1.20 \text{ psia}} = \mathbf{108^\circ\text{F}} \quad (\text{from EES})$$

**15-105** Octane is burned steadily with 60 percent excess air. The dew-point temperature of the water vapor in the products is to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.

**Properties** The molar masses of  $C_8H_{18}$  and air are 114 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $CO_2$ ,  $H_2O$ ,  $N_2$ , and some free  $O_2$ . Considering 1 kmol  $C_8H_{18}$ , the combustion equation can be written as

where  $a_{th}$  is the stoichiometric coefficient and is determined from the  $O_2$  balance,

$$1.6a_{th} = 8 + 4.5 + 0.6a_{th} \longrightarrow a_{th} = 12.5$$

Thus,

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{prod}} \right) P_{prod} = \left( \frac{9 \text{ kmol}}{(8 + 9 + 7.5 + 75.2) \text{ kmol}} \right) (101.325 \text{ kPa}) = 9.147 \text{ kPa}$$

Thus,

$$T_{dp} = T_{sat@9.147 \text{ kPa}} = \mathbf{44.1^\circ C} \quad (\text{from EES})$$

**15-106** Methane is burned steadily with 50 percent excess air. The dew-point temperature of the water vapor in the products is to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.

**Properties** The molar masses of  $\text{CH}_4$  and air are 16 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol  $\text{CH}_4$ , the combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1.5a_{\text{th}} = 1 + 1 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

Thus,

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left( \frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left( \frac{2 \text{ kmol}}{(1 + 2 + 1 + 11.28) \text{ kmol}} \right) (101.325 \text{ kPa}) = 13.26 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@13.26 \text{ kPa}} = \mathbf{51.4^\circ\text{C}} \quad (\text{from EES})$$

**15-107** The higher and lower heating values of gaseous methane are to be determined and compared to the listed values.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$ . 3 Combustion gases are ideal gases.

**Properties** The molar masses of C,  $\text{O}_2$ ,  $\text{H}_2$ , and air are 12, 32, 2, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion reaction with stoichiometric air is

Both the reactants and the products are taken to be at the standard reference state of  $25^\circ\text{C}$  and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that  $\text{N}_2$  and  $\text{O}_2$  are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{CH}_4}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$\begin{aligned} h_C &= (1 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (2 \text{ kmol})(-285,830 \text{ kJ/kmol}) - (1 \text{ kmol})(-74,850 \text{ kJ/kmol}) \\ &= -890,330 \text{ kJ/kmol methane} \end{aligned}$$

The HHV of the methane is

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{890,330 \text{ kJ/kmol CH}_4}{16.043 \text{ kg/kmol CH}_4} = \mathbf{55,500 \text{ kJ/kg CH}_4}$$

The listed value from Table A-27 is **55,530 kJ/kg**. For the LHV, the water in the products is taken to be vapor. Then,

$$\begin{aligned} h_C &= (1 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (2 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-74,850 \text{ kJ/kmol}) \\ &= -802,310 \text{ kJ/kmol methane} \end{aligned}$$

The LHV of the coal is then

$$\text{LHV} = \frac{-h_C}{M_m} = \frac{-802,310 \text{ kJ/kmol CH}_4}{16.043 \text{ kg/kmol CH}_4} = \mathbf{50,010 \text{ kJ/kg CH}_4}$$

The listed value from Table A-27 is **50,050 kJ/kg**. The calculated and listed values are practically identical.

**15-108** An expression for the HHV of a gaseous alkane  $C_nH_{2n+2}$  in terms of  $n$  is to be developed.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $CO_2$ ,  $H_2O$ , and  $N_2$ . 3 Combustion gases are ideal gases.

**Analysis** The complete reaction balance for 1 kmol of fuel is

Both the reactants and the products are taken to be at the standard reference state of  $25^\circ C$  and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that  $N_2$  and  $O_2$  are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N\bar{h}_f^\circ)_{CO_2} + (N\bar{h}_f^\circ)_{H_2O} - (N\bar{h}_f^\circ)_{fuel}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$h_C = n(-393,520) + (n+1)(-285,830) - (\bar{h}_f^\circ)_{fuel}$$

The HHV of the fuel is

$$HHV = \frac{-h_C}{M_{fuel}} = \frac{n(-393,520) + (n+1)(-285,830) - (\bar{h}_f^\circ)_{fuel}}{M_{fuel}}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$LHV = \frac{n(-393,520) + (n+1)(-241,820) - (\bar{h}_f^\circ)_{fuel}}{M_{fuel}}$$

**15-109** A coal from Colorado is burned with 10 percent excess air during a steady-flow combustion process. The fraction of the water in the combustion products that is liquid and the fraction that is vapor are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Properties** The molar masses of C, H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The mass fractions of the constituent of the coal when the ash is substituted are

$$mf_C = \frac{m_C}{m_{\text{total}}} = \frac{79.61 \text{ kg}}{(100 - 8.62) \text{ kg}} = \frac{79.61 \text{ kg}}{91.38 \text{ kg}} = 0.8712$$

$$mf_{H_2} = \frac{m_{H_2}}{m_{\text{total}}} = \frac{4.66 \text{ kg}}{91.38 \text{ kg}} = 0.05100$$

$$mf_{O_2} = \frac{m_{O_2}}{m_{\text{total}}} = \frac{4.76 \text{ kg}}{91.38 \text{ kg}} = 0.05209$$

$$mf_{N_2} = \frac{m_{N_2}}{m_{\text{total}}} = \frac{1.83 \text{ kg}}{91.38 \text{ kg}} = 0.02003$$

$$mf_S = \frac{m_S}{m_{\text{total}}} = \frac{0.52 \text{ kg}}{91.38 \text{ kg}} = 0.00569$$

|                      |
|----------------------|
| 79.61% C             |
| 4.66% H <sub>2</sub> |
| 4.76% O <sub>2</sub> |
| 1.83% N <sub>2</sub> |
| 0.52% S              |
| 8.62% ash            |
| (by mass)            |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$N_C = \frac{m_C}{M_C} = \frac{87.12 \text{ kg}}{12 \text{ kg/kmol}} = 7.26 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.10 \text{ kg}}{2 \text{ kg/kmol}} = 2.55 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{5.209 \text{ kg}}{32 \text{ kg/kmol}} = 0.1628 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{2.003 \text{ kg}}{28 \text{ kg/kmol}} = 0.07154 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.569 \text{ kg}}{32 \text{ kg/kmol}} = 0.01778 \text{ kmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 7.26 + 2.55 + 0.1628 + 0.07154 + 0.01778 = 10.062 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{7.26 \text{ kmol}}{10.06 \text{ kmol}} = 0.7215$$

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.55 \text{ kmol}}{10.06 \text{ kmol}} = 0.2535$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.1628 \text{ kmol}}{10.06 \text{ kmol}} = 0.01618$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.07154 \text{ kmol}}{10.06 \text{ kmol}} = 0.00711$$

$$y_S = \frac{N_S}{N_m} = \frac{0.01778 \text{ kmol}}{10.06 \text{ kmol}} = 0.00177$$

Then, the combustion equation in this case may be written as

According to the oxygen balance,

$$\text{O}_2 \text{ balance: } 0.01618 + 1.1a_{\text{th}} = 0.7215 + (0.5)(0.2535) + (0.00177) + 0.1a_{\text{th}} \longrightarrow a_{\text{th}} = 0.8339$$

Substituting,

If the mixture leaves the boiler saturated with water, the partial pressure of water in the product mixture would be

$$P_v = P_{\text{sat}@50^\circ\text{C}} = 12.352 \text{ kPa}$$

and the water mole fraction would be

$$y_v = \frac{P_v}{P} = \frac{12.352 \text{ kPa}}{101.325 \text{ kPa}} = 0.1219$$

The actual mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{0.2535 \text{ kmol}}{(0.7215 + 0.2535 + 0.0018 + 3.449 + 0.0834) \text{ kmol}} = 0.0562$$

Since the actual mole fraction of the water is less than that when the mixture is saturated, the mixture never becomes saturated and hence, no condensate is formed. All of the water in the mixture is then in the vapor form at this temperature.

**15-110** Butane is burned with stoichiometric amount of air. The fraction of the water in the products that is liquid is to be determined.

**Assumptions** **1** Combustion is complete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases.

**Analysis** The fuel is burned completely with the air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$ . Considering 1 kmol  $\text{C}_4\text{H}_{10}$ , the combustion equation can be written as

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{5 \text{ kmol}}{(4 + 5 + 24.44) \text{ kmol}} = 0.1495$$

The saturation pressure for the water vapor is

$$P_v = P_{\text{sat}@40^\circ\text{C}} = 7.3851 \text{ kPa}$$

When the combustion gases are saturated, the mole fraction of the water vapor will be

$$y_g = \frac{P_v}{P} = \frac{7.3851 \text{ kPa}}{101.325 \text{ kPa}} = 0.0729$$

The mole fraction of the liquid water is then

$$y_f = y_v - y_g = 0.1495 - 0.0729 = 0.0766$$

Thus, the fraction of liquid water in the combustion products is

$$f_{\text{liquid}} = \frac{y_f}{y_g} = \frac{0.0766}{0.1495} = \mathbf{0.512}$$

**15-111** CO gas is burned with air during a steady-flow combustion process. The rate of heat transfer from the combustion chamber is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 Combustion is complete.

**Properties** The molar masses of CO and air are 28 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** We first need to calculate the amount of air used per kmol of CO before we can write the combustion equation,

$$\nu_{\text{CO}} = \frac{RT}{P} = \frac{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(310 \text{ K})}{(110 \text{ kPa})} = 0.836 \text{ m}^3/\text{kg}$$

$$\dot{m}_{\text{CO}} = \frac{\dot{V}_{\text{CO}}}{\nu_{\text{CO}}} = \frac{0.4 \text{ m}^3/\text{min}}{0.836 \text{ m}^3/\text{kg}} = 0.478 \text{ kg/min}$$

Then the molar air-fuel ratio becomes

$$\overline{\text{AF}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{\dot{m}_{\text{air}} / M_{\text{air}}}{\dot{m}_{\text{fuel}} / M_{\text{fuel}}} = \frac{(1.5 \text{ kg/min}) / (29 \text{ kg/kmol})}{(0.478 \text{ kg/min}) / (28 \text{ kg/kmol})} = 3.03 \text{ kmol air/kmol fuel}$$

Thus the number of moles of  $\text{O}_2$  used per mole of CO is  $3.03/4.76 = 0.637$ . Then the combustion equation in this case can be written as

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance     | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{310 \text{ K}}$<br>kJ/kmol | $\bar{h}_{900 \text{ K}}$<br>kJ/kmol |
|---------------|------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|
| CO            | -110,530                     | 8669                                 | 9014                                 | 27,066                               |
| $\text{O}_2$  | 0                            | 8682                                 | ---                                  | 27,928                               |
| $\text{N}_2$  | 0                            | 8669                                 | ---                                  | 26,890                               |
| $\text{CO}_2$ | -393,520                     | 9364                                 | ---                                  | 37,405                               |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 37,405 - 9364) + (0.137)(0 + 27,928 - 8682) \\ &\quad + (2.4)(0 + 26,890 - 8669) - (1)(-110,530 + 9014 - 8669) - 0 - 0 \\ &= -208,927 \text{ kJ/kmol of CO} \end{aligned}$$

Then the rate of heat transfer for a mass flow rate of 0.956 kg/min for CO becomes

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = \left( \frac{\dot{m}}{M} \right) Q_{\text{out}} = \left( \frac{0.478 \text{ kg/min}}{28 \text{ kg/kmol}} \right) (208,927 \text{ kJ/kmol}) = \mathbf{3567 \text{ kJ/min}}$$

**15-112** Methane gas is burned steadily with dry air. The volumetric analysis of the products is given. The percentage of theoretical air used and the heat transfer from the combustion chamber are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions.

**Analysis** (a) Considering 100 kmol of dry products, the combustion equation can be written as

The unknown coefficients  $x$ ,  $a$ , and  $b$  are determined from mass balances,

$$\text{N}_2 : 3.76a = 83.23 \longrightarrow a = 22.14$$

$$\text{C} : x = 5.20 + 0.33 \longrightarrow x = 5.53$$

$$\text{H} : 4x = 2b \longrightarrow b = 11.06$$

$$(\text{Check } \text{O}_2 : a = 5.20 + 0.165 + 11.24 + b/2 \longrightarrow 22.14 = 22.14)$$

Thus,  $5.53\text{CH}_4 + 22.14[\text{O}_2 + 3.76\text{N}_2] \longrightarrow 5.20\text{CO}_2 + 0.33\text{CO} + 11.24\text{O}_2 + 83.23\text{N}_2 + 11.06\text{H}_2\text{O}$

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.53

To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2 : a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2.0$$

$$\text{Then, Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(4.0)(4.76) \text{ kmol}}{(2.0)(4.76) \text{ kmol}} = 200\%$$

(b) Under steady-flow conditions, energy balance applied on the combustion chamber reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{290 \text{ K}}$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{700 \text{ K}}$<br>kJ/kmol |
|--------------------------|------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|
| $\text{CH}_4 (g)$        | -74,850                      | ---                                  | ---                                  | ---                                  |
| $\text{O}_2$             | 0                            | 8443                                 | 8682                                 | 21,184                               |
| $\text{N}_2$             | 0                            | 8432                                 | 8669                                 | 20,604                               |
| $\text{H}_2\text{O} (g)$ | -241,820                     | ---                                  | 9904                                 | 24,088                               |
| $\text{CO}$              | -110,530                     | ---                                  | 8669                                 | 20,690                               |
| $\text{CO}_2$            | -393,520                     | ---                                  | 9364                                 | 27,125                               |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (0.94)(-393,520 + 27,125 - 9364) + (0.06)(-110,530 + 20,690 - 8669) \\ &\quad + (2)(-241,820 + 24,088 - 9904) + (2.03)(0 + 21,184 - 8682) + (15.04)(0 + 20,604 - 8669) \\ &\quad - (1)(-74,850 + h_{298} - h_{298}) - (4)(0 + 8443 - 8682) - (15.04)(0 + 8432 - 8669) \\ &= -530,022 \text{ kJ/kmolCH}_4 \end{aligned}$$

$$\text{or } Q_{\text{out}} = 530,022 \text{ kJ/kmol CH}_4$$

**15-113** Propane gas is burned with air during a steady-flow combustion process. The adiabatic flame temperature is to be determined for different cases.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ( $Q = 0$ ) with no work interactions ( $W = 0$ ). Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h}_T - \bar{h}^\circ)_P = (N \bar{h}_f^\circ)_{\text{C}_3\text{H}_8}$$

since all the reactants are at the standard reference temperature of 25°C, and  $\bar{h}_f^\circ = 0$  for  $\text{O}_2$  and  $\text{N}_2$ .

(a) The theoretical combustion equation of  $\text{C}_3\text{H}_8$  with stoichiometric amount of air is

From the tables,

| Substance                 | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol |
|---------------------------|------------------------------|-------------------------------------|
| $\text{C}_3\text{H}_8(g)$ | -103,850                     | ---                                 |
| $\text{O}_2$              | 0                            | 8682                                |
| $\text{N}_2$              | 0                            | 8669                                |
| $\text{H}_2\text{O}(g)$   | -241,820                     | 9904                                |
| CO                        | -110,530                     | 8669                                |
| $\text{CO}_2$             | -393,520                     | 9364                                |

Thus,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (18.8)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

It yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} = 2,274,675 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $2,274,675 / (3 + 4 + 18.8) = 88,165 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 2650 K for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_P$  will be close to 2650 K, but somewhat under it because of the higher specific heats of  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

$$\begin{aligned} \text{At 2400 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= (3)(125,152) + (4)(103,508) + (18.8)(79,320) \\ &= 2,280,704 \text{ kJ (Higher than 2,274,675 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At 2350 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= (3)(122,091) + (4)(100,846) + (18.8)(77,496) \\ &= 2,226,582 \text{ kJ (Lower than 2,274,675 kJ)} \end{aligned}$$

By interpolation,  $T_P = 2394 \text{ K}$

(b) The balanced combustion equation for complete combustion with 300% theoretical air is

Substituting known numerical values,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (10)(0 + \bar{h}_{\text{O}_2} - 8682) + (56.4)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

which yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 10\bar{h}_{\text{O}_2} + 56.4\bar{h}_{\text{N}_2} = 2,687,450 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $2,687,449 / (3 + 4 + 10 + 56.4) = 36,614 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 1200 K for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_p$  will be close to 1200 K, but somewhat under it because of the higher specific heats of  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

At 1160 K:

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 10\bar{h}_{\text{O}_2} + 56.4\bar{h}_{\text{N}_2} = (3)(51,602) + (4)(42,642) + (10)(37,023) + (56.4)(35,430) = 2,693,856 \text{ kJ (Higher than 2,687,450 kJ)}$$

At 1140 K:

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 10\bar{h}_{\text{O}_2} + 56.4\bar{h}_{\text{N}_2} = (3)(50,484) + (4)(41,780) + (10)(36,314) + (56.4)(34,760) = 2,642,176 \text{ kJ (Lower than 2,687,450 kJ)}$$

By interpolation,  $T_p = 1158 \text{ K}$

(c) The balanced combustion equation for incomplete combustion with 95% theoretical air is

Substituting known numerical values,

$$(2.5)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (0.5)(-110,530 + \bar{h}_{\text{CO}} - 8669) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (17.86)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

which yields

$$2.5\bar{h}_{\text{CO}_2} + 0.5\bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 17.86\bar{h}_{\text{N}_2} = 2,124,684 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $2,124,684 / (2.5 + 0.5 + 4 + 17.86) = 85,466 \text{ kJ/kmol}$ . This enthalpy value corresponds to about 2550 K for  $\text{N}_2$ . Noting that the majority of the moles are  $\text{N}_2$ ,  $T_p$  will be close to 2550 K, but somewhat under it because of the higher specific heats of  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

At 2350 K:

$$2.5\bar{h}_{\text{CO}_2} + 0.5\bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 17.86\bar{h}_{\text{N}_2} = (2.5)(122,091) + (0.5)(78,178) + (4)(100,846) + (17.86)(77,496) = 2,131,779 \text{ kJ (Higher than 2,124,684 kJ)}$$

At 2300 K:

$$2.5\bar{h}_{\text{CO}_2} + 0.5\bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 17.86\bar{h}_{\text{N}_2} = (2.5)(119,035) + (0.5)(76,345) + (4)(98,199) + (17.86)(75,676) = 2,080,129 \text{ kJ (Lower than 2,124,684 kJ)}$$

By interpolation,  $T_p = 2343 \text{ K}$

**15-114** The highest possible temperatures that can be obtained when liquid gasoline is burned steadily with air and with pure oxygen are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

**Analysis** The highest possible temperature that can be achieved during a combustion process is the temperature which occurs when a fuel is burned completely with stoichiometric amount of air in an adiabatic combustion chamber. It is determined from

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h}_T - \bar{h}^\circ)_P = (N \bar{h}_f^\circ)_{C_8H_{18}}$$

since all the reactants are at the standard reference temperature of 25°C, and for O<sub>2</sub> and N<sub>2</sub>. The theoretical combustion equation of C<sub>8</sub>H<sub>18</sub> air is

From the tables,

| Substance                          | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol |
|------------------------------------|------------------------------|-------------------------------------|
| C <sub>8</sub> H <sub>18</sub> (ℓ) | -249,950                     | ---                                 |
| O <sub>2</sub>                     | 0                            | 8682                                |
| N <sub>2</sub>                     | 0                            | 8669                                |
| H <sub>2</sub> O (g)               | -241,820                     | 9904                                |
| CO <sub>2</sub>                    | -393,520                     | 9364                                |

Thus,

$$(8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) + (47)(0 + \bar{h}_{N_2} - 8669) = (1)(-249,950)$$

It yields  $8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} = 5,646,081$  kJ

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $5,646,081/(8 + 9 + 47) = 88,220$  kJ/kmol. This enthalpy value corresponds to about 2650 K for N<sub>2</sub>. Noting that the majority of the moles are N<sub>2</sub>,  $T_P$  will be close to 2650 K, but somewhat under it because of the higher specific heat of H<sub>2</sub>O.

$$\begin{aligned} \text{At 2400 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} &= (8)(125,152) + (9)(103,508) + (47)(79,320) \\ &= 5,660,828 \text{ kJ (Higher than 5,646,081 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At 2350 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} &= (8)(122,091) + (9)(100,846) + (47)(77,496) \\ &= 5,526,654 \text{ kJ (Lower than 5,646,081 kJ)} \end{aligned}$$

By interpolation,  $T_P = 2395$  K

If the fuel is burned with stoichiometric amount of pure O<sub>2</sub>, the combustion equation would be

$$\text{Thus, } (8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) = (1)(-249,950)$$

$$\text{It yields } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = 5,238,638 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields  $5,238,638/(8 + 9) = 308,155$  kJ/kmol. This enthalpy value is higher than the highest enthalpy value listed for H<sub>2</sub>O and CO<sub>2</sub>. Thus an estimate of the adiabatic flame temperature can be obtained by extrapolation.

$$\text{At 3200 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = (8)(174,695) + (9)(147,457) = 2,724,673 \text{ kJ}$$

$$\text{At 3250 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = (8)(177,822) + (9)(150,272) = 2,775,024 \text{ kJ}$$

By extrapolation, we get  $T_P = 3597$  K. However, the solution of this problem using EES gives **5645 K**. The large difference between these two values is due to extrapolation.

**15-115** Methyl alcohol vapor is burned with the stoichiometric amount of air in a combustion chamber. The maximum pressure that can occur in the combustion chamber if the combustion takes place at constant volume and the maximum volume of the combustion chamber if the combustion occurs at constant pressure are to be determined.

**Assumptions** 1 Combustion is complete. 2 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** (a) The combustion equation of  $\text{CH}_3\text{OH}(g)$  with stoichiometric amount of air is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1 + 2a_{\text{th}} = 2 + 2 \longrightarrow a_{\text{th}} = 1.5$$

Thus,

The final temperature in the tank is determined from the energy balance relation  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  for reacting closed systems under adiabatic conditions ( $Q = 0$ ) with no work interactions ( $W = 0$ ),

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Assuming both the reactants and the products to behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ . It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_P} - \bar{h}_{298\text{K}} - R_u T)_P = \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

| Substance                | $\bar{h}_f^\circ$ | $\bar{h}_{298\text{K}}$ |
|--------------------------|-------------------|-------------------------|
|                          | kJ/kmol           | kJ/kmol                 |
| $\text{CH}_3\text{OH}$   | -200,670          | ---                     |
| $\text{O}_2$             | 0                 | 8682                    |
| $\text{N}_2$             | 0                 | 8669                    |
| $\text{H}_2\text{O} (g)$ | -241,820          | 9904                    |
| $\text{CO}_2$            | -393,520          | 9364                    |

Thus,

$$\begin{aligned} & (1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_P) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_P) \\ & + (5.64)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_P) = (1)(-200,670 - 8.314 \times 298) + (1.5)(0 - 8.314 \times 298) \\ & \quad + (5.64)(0 - 8.314 \times 298) \end{aligned}$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} - 71833 \times T_P = 734,388 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

At 2850 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} - 71.833 \times T_P = (1)(152,908) + (2)(127,952) + (5.64)(95,859) - (71.833)(2850) \\ = 744,733 \text{ kJ (Higher than 734,388 kJ)}$$

At 2800 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} - 71.833 \times T_P = (1)(149,808) + (2)(125,198) + (5.64)(94,014) - (71.833)(2800) \\ = 729,311 \text{ kJ (Lower than 734,388 kJ)}$$

By interpolation  $T_P = 2816 \text{ K}$

Since both the reactants and the products behave as ideal gases, the final (maximum) pressure that can occur in the combustion chamber is determined to be

$$\frac{P_1 V}{P_2 V} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(8.64 \text{ kmol})(2816 \text{ K})}{(8.14 \text{ kmol})(298 \text{ K})} (98 \text{ kPa}) = \mathbf{983 \text{ kPa}}$$

(b) The combustion equation of  $\text{CH}_3\text{OH}(g)$  remains the same in the case of constant pressure. Further, the boundary work in this case can be combined with the  $u$  terms so that the first law relation can be expressed in terms of enthalpies just like the steady-flow process,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Since both the reactants and the products behave as ideal gases, we have  $h = h(T)$ . Also noting that  $Q = 0$  for an adiabatic combustion process, the 1st law relation reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_P} - \bar{h}_{298 \text{ K}})_P = \sum N_R (\bar{h}_f^\circ)_R$$

since the reactants are at the standard reference temperature of  $25^\circ\text{C}$ . Then using data from the mini table above, we get

$$(1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (5.64)(0 + \bar{h}_{\text{N}_2} - 8669) \\ = (1)(-200,670) + (1.5)(0) + (5.64)(0)$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} = 754,555 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

$$\text{At } 2350 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} = (1)(122,091) + (2)(100,846) + (5.64)(77,496) \\ = 760,860 \text{ kJ (Higher than 754,555 kJ)}$$

$$\text{At } 2300 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} = (1)(119,035) + (2)(98,199) + (5.64)(75,676) \\ = 742,246 \text{ kJ (Lower than 754,555 kJ)}$$

By interpolation,  $T_P = 2333 \text{ K}$

Treating both the reactants and the products as ideal gases, the final (maximum) volume that the combustion chamber can have is determined to be

$$\frac{P V_1}{P V_2} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow V_2 = \frac{N_2 T_2}{N_1 T_1} V_1 = \frac{(8.64 \text{ kmol})(2333 \text{ K})}{(8.14 \text{ kmol})(298 \text{ K})} (0.8 \text{ L}) = \mathbf{6.65 \text{ L}}$$

**15-116** Problem 15-115 is reconsidered. The effect of the initial volume of the combustion chamber on the maximum pressure of the chamber for constant volume combustion or the maximum volume of the chamber for constant pressure combustion is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

### Constant pressure combustion of CH<sub>3</sub>OH

### Constant volume combustion of CH<sub>3</sub>OH

**15-117** Methane is burned with the stoichiometric amount of air in a combustion chamber. The maximum pressure that can occur in the combustion chamber if the combustion takes place at constant volume and the maximum volume of the combustion chamber if the combustion occurs at constant pressure are to be determined.

**Assumptions** 1 Combustion is complete. 2 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** (a) The combustion equation of  $\text{CH}_4(g)$  with stoichiometric amount of air is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

Thus,

The final temperature in the tank is determined from the energy balance relation  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  for reacting closed systems under adiabatic conditions ( $Q = 0$ ) with no work interactions ( $W = 0$ ),

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ . It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_P} - \bar{h}_{298\text{K}} - R_u T)_P = \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol |
|--------------------------|------------------------------|------------------------------------|
| $\text{CH}_4$            | -74,850                      | ---                                |
| $\text{O}_2$             | 0                            | 8682                               |
| $\text{N}_2$             | 0                            | 8669                               |
| $\text{H}_2\text{O} (g)$ | -241,820                     | 9904                               |
| $\text{CO}_2$            | -393,520                     | 9364                               |

Thus,

$$\begin{aligned} & (1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_P) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_P) \\ & + (7.52)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_P) = (1)(-74,850 - 8.314 \times 298) + (2)(0 - 8.314 \times 298) \\ & \quad + (7.52)(0 - 8.314 \times 298) \end{aligned}$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} - 87.463 \times T_P = 870,609 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

At 2850 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} - 87.463 \times T_p = (1)(152,908) + (2)(127,952) + (7.52)(95,859) - (87.463)(2850) \\ = 880,402 \text{ kJ (Higher than 870,609 kJ)}$$

At 2800 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} - 87.463 \times T_p = (1)(149,808) + (2)(125,198) + (7.52)(94,014) - (87.463)(2800) \\ = 862,293 \text{ kJ (Lower than 870,609 kJ)}$$

By interpolation,  $T_p = 2823 \text{ K}$

Treating both the reactants and the products as ideal gases, the final (maximum) pressure that can occur in the combustion chamber is determined to be

$$\frac{P_1 V}{P_2 V} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(10.52 \text{ kmol})(2823 \text{ K})}{(10.52 \text{ kmol})(298 \text{ K})} (98 \text{ kPa}) = \mathbf{928 \text{ kPa}}$$

(b) The combustion equation of  $\text{CH}_4(g)$  remains the same in the case of constant pressure. Further, the boundary work in this case can be combined with the  $u$  terms so that the first law relation can be expressed in terms of enthalpies just like the steady-flow process,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Again since both the reactants and the products behave as ideal gases, we have  $h = h(T)$ . Also noting that  $Q = 0$  for an adiabatic combustion process, the energy balance relation reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_p} - \bar{h}_{298 \text{ K}})_P = \sum N_R (\bar{h}_f^\circ)_R$$

since the reactants are at the standard reference temperature of  $25^\circ\text{C}$ . Then using data from the mini table above, we get

$$(1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (7.52)(0 + \bar{h}_{\text{N}_2} - 8669) \\ = (1)(-74,850) + (2)(0) + (7.52)(0)$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} = 896,673 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

$$\text{At } 2350 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} = (1)(122,091) + (2)(100,846) + (7.52)(77,496) \\ = 906,553 \text{ kJ (Higher than 896,673 kJ)}$$

$$\text{At } 2300 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} = (1)(119,035) + (2)(98,199) + (7.52)(75,676) \\ = 884,517 \text{ kJ (Lower than 896,673 kJ)}$$

By interpolation,  $T_p = 2328 \text{ K}$

Treating both the reactants and the products as ideal gases, the final (maximum) volume that the combustion chamber can have is determined to be

$$\frac{P V_1}{P V_2} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow V_2 = \frac{N_2 T_2}{N_1 T_1} V_1 = \frac{(10.52 \text{ kmol})(2328 \text{ K})}{(10.52 \text{ kmol})(298 \text{ K})} (0.8 \text{ L}) = \mathbf{6.25 \text{ L}}$$

**15-118** A mixture of 40% by volume methane,  $\text{CH}_4$ , and 60% by volume propane,  $\text{C}_3\text{H}_8$ , is burned completely with theoretical air. The amount of water formed during combustion process that will be condensed is to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$  only.

**Properties** The molar masses of C,  $\text{H}_2$ ,  $\text{O}_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The combustion equation in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. The coefficient  $a_{\text{th}}$  and other coefficients are to be determined from the mass balances

Carbon balance:  $B = 0.4 + 3 \times 0.6 = 2.2$

Hydrogen balance:  $2D = 4 \times 0.4 + 8 \times 0.6 = 2D \longrightarrow D = 3.2$

Oxygen balance:  $2a_{\text{th}} = 2B + D \longrightarrow 2a_{\text{th}} = 2(2.2) + 3.2 \longrightarrow a_{\text{th}} = 3.8$

Nitrogen balance:  $3.76a_{\text{th}} = F \longrightarrow 3.76(3.8) = F \longrightarrow F = 14.29$

Then, we write the balanced reaction equation as

The vapor mole fraction in the products is

$$y_v = \frac{3.2}{2.2 + 3.2 + 14.29} = 0.1625$$

The partial pressure of water in the products is

$$P_{v,\text{prod}} = y_v P_{\text{prod}} = (0.1625)(100 \text{ kPa}) = 16.25 \text{ kPa}$$

The dew point temperature of the products is

$$T_{\text{dp}} = T_{\text{sat}@16.25 \text{ kPa}} = 55.64^\circ\text{C}$$

The partial pressure of the water vapor remaining in the products at the product temperature is

$$P_v = P_{\text{sat}@39^\circ\text{C}} = 7.0 \text{ kPa}$$

The kmol of water vapor in the products at the product temperature is

$$P_v = \frac{N_v}{N_{\text{total,product}}} P_{\text{prod}}$$

$$7.0 \text{ kPa} = \frac{N_v}{2.2 + N_v + 14.29}$$

$$N_v = 1.241 \text{ kmol}$$

The kmol of water condensed is

$$N_w = 3.2 - 1.241 = \mathbf{1.96 \text{ kmol water/kmol fuel}}$$

**15-119** Methane is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Properties** The molar masses of  $\text{CH}_4$  and air are 16 kg/kmol and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The fuel is burned completely with the excess air, and thus the products will contain only  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{N}_2$ , and some free  $\text{O}_2$ . Considering 1 kmol  $\text{CH}_4$ , the combustion equation can be written as

Under steady-flow conditions the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber

with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance                | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{500\text{K}}$<br>kJ/kmol |
|--------------------------|------------------------------|------------------------------------|------------------------------------|
| $\text{CH}_4$            | -74,850                      | ---                                | ---                                |
| $\text{O}_2$             | 0                            | 8682                               | 14,770                             |
| $\text{N}_2$             | 0                            | 8669                               | 14,581                             |
| $\text{H}_2\text{O} (g)$ | -241,820                     | 9904                               | 16,828                             |
| $\text{CO}_2$            | -393,520                     | 9364                               | 17,678                             |

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 17,678 - 9364) + (2)(-241,820 + 16,828 - 9904) \\ &\quad + (1)(0 + 14,770 - 8682) + (11.28)(0 + 14,581 - 8669) - (1)(-74,850) \\ &= -707,373 \text{ kJ/kmol of fuel} \end{aligned}$$

The heat loss per unit mass of the fuel is

$$Q_{\text{out}} = \frac{707,373 \text{ kJ/kmol of fuel}}{16 \text{ kg/kmol of fuel}} = 44,211 \text{ kJ/kg fuel}$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$\frac{m_s}{m_f} = \frac{Q_{\text{out}}}{\Delta h_s} = \frac{44,211 \text{ kJ/kg fuel}}{(3214.5 - 852.26) \text{ kJ/kg steam}} = \mathbf{18.72 \text{ kg steam/kg fuel}}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                      | $N_i$ | $y_i$  | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$              |
|----------------------|-------|--------|-----------------------------------|--------------------|------------------------------|
| CH <sub>4</sub>      | 1     | ---    | 186.16                            | 0                  | 186.16                       |
| O <sub>2</sub>       | 3     | 0.21   | 205.04                            | -12.98             | 654.06                       |
| N <sub>2</sub>       | 11.28 | 0.79   | 191.61                            | -1.960             | 2183.47                      |
|                      |       |        |                                   |                    | $S_R = 3023.69 \text{ kJ/K}$ |
| CO <sub>2</sub>      | 1     | 0.0654 | 234.814                           | -22.67             | 257.48                       |
| H <sub>2</sub> O (g) | 2     | 0.1309 | 206.413                           | -16.91             | 446.65                       |
| O <sub>2</sub>       | 1     | 0.0654 | 220.589                           | -22.67             | 243.26                       |
| N <sub>2</sub>       | 11.28 | 0.7382 | 206.630                           | -2.524             | 2359.26                      |
|                      |       |        |                                   |                    | $S_P = 3306.65 \text{ kJ/K}$ |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 3306.65 - 3023.69 + \frac{707,373}{298} = 2657 \text{ kJ/K (per kmol fuel)}$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$\Delta X_{\text{gases}} = -X_{\text{dest}} = -T_0 S_{\text{gen}} = -(298 \text{ K})(2657 \text{ kJ/K}) = -791,786 \text{ kJ/kmol fuel}$$

Per unit mass basis,

$$\Delta X_{\text{gases}} = \frac{-791,786 \text{ kJ/kmol fuel}}{16 \text{ kg/kmol}} = \mathbf{-49,490 \text{ kJ/kg fuel}}$$

Note that the exergy change is negative since the exergy of combustion gases decreases.

(c) The exergy change of the steam stream is

$$\Delta X_{\text{steam}} = \Delta h - T_0 \Delta s = (3214.5 - 852.26) - (298)(6.7714 - 2.3305) = \mathbf{1039 \text{ kJ/kg steam}}$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$\begin{aligned} X_{\text{dest}} &= - \left( \frac{m_s}{m_f} \Delta X_{\text{steam}} + \Delta X_{\text{gases}} \right) \\ &= - \left[ (19.72 \text{ kg steam/kg fuel})(1039 \text{ kJ/kg steam}) + (-49,490 \text{ kJ/kg fuel}) \right] \\ &= \mathbf{30,040 \text{ kJ/kg fuel}} \end{aligned}$$

**15-120** A coal from Utah is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible. 5 The effect of sulfur on the energy and entropy balances is negligible.

**Properties** The molar masses of C, H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

**Analysis** (a) The mass fractions of the constituent of the coal when the ash is substituted are

$$\begin{aligned} \text{mf}_C &= \frac{m_C}{m_{\text{total}}} = \frac{61.40 \text{ kg}}{(100 - 5.00) \text{ kg}} = \frac{61.40 \text{ kg}}{95.00 \text{ kg}} = 0.6463 \\ \text{mf}_{\text{H}_2} &= \frac{m_{\text{H}_2}}{m_{\text{total}}} = \frac{5.79 \text{ kg}}{95.00 \text{ kg}} = 0.06095 \\ \text{mf}_{\text{O}_2} &= \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{25.31 \text{ kg}}{95.00 \text{ kg}} = 0.2664 \\ \text{mf}_{\text{N}_2} &= \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1.09 \text{ kg}}{95.00 \text{ kg}} = 0.01147 \\ \text{mf}_S &= \frac{m_S}{m_{\text{total}}} = \frac{1.41 \text{ kg}}{95.00 \text{ kg}} = 0.01484 \end{aligned}$$

|                       |
|-----------------------|
| 61.40% C              |
| 5.79% H <sub>2</sub>  |
| 25.31% O <sub>2</sub> |
| 1.09% N <sub>2</sub>  |
| 1.41% S               |
| 5.00% ash             |
| (by mass)             |

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$\begin{aligned} N_C &= \frac{m_C}{M_C} = \frac{64.63 \text{ kg}}{12 \text{ kg/kmol}} = 5.386 \text{ kmol} \\ N_{\text{H}_2} &= \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{6.095 \text{ kg}}{2 \text{ kg/kmol}} = 3.048 \text{ kmol} \\ N_{\text{O}_2} &= \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{26.64 \text{ kg}}{32 \text{ kg/kmol}} = 0.8325 \text{ kmol} \\ N_{\text{N}_2} &= \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{1.147 \text{ kg}}{28 \text{ kg/kmol}} = 0.04096 \text{ kmol} \\ N_S &= \frac{m_S}{M_S} = \frac{1.484 \text{ kg}}{32 \text{ kg/kmol}} = 0.04638 \text{ kmol} \end{aligned}$$

The mole number of the mixture and the mole fractions are

$$\begin{aligned} N_m &= 5.386 + 3.048 + 0.8325 + 0.04096 + 0.04638 = 9.354 \text{ kmol} \\ y_C &= \frac{N_C}{N_m} = \frac{5.386 \text{ kmol}}{9.354 \text{ kmol}} = 0.5758 \\ y_{\text{H}_2} &= \frac{N_{\text{H}_2}}{N_m} = \frac{3.048 \text{ kmol}}{9.354 \text{ kmol}} = 0.3258 \\ y_{\text{O}_2} &= \frac{N_{\text{O}_2}}{N_m} = \frac{0.8325 \text{ kmol}}{9.354 \text{ kmol}} = 0.0890 \\ y_{\text{N}_2} &= \frac{N_{\text{N}_2}}{N_m} = \frac{0.04096 \text{ kmol}}{9.354 \text{ kmol}} = 0.00438 \\ y_S &= \frac{N_S}{N_m} = \frac{0.04638 \text{ kmol}}{9.354 \text{ kmol}} = 0.00496 \end{aligned}$$

Then, the combustion equation in this case may be written as

According to the oxygen balance,

$$\text{O}_2 \text{ balance: } 0.0890 + 1.5a_{\text{th}} = 0.5758 + 0.5 \times 0.3258 + 0.00496 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 0.6547$$

Substituting,

The apparent molecular weight of the coal is

$$M_m = \frac{m_m}{N_m} = \frac{(0.5758 \times 12 + 0.3258 \times 2 + 0.0890 \times 32 + 0.00438 \times 28 + 0.00496 \times 32) \text{ kg}}{(0.5758 + 0.3258 + 0.0890 + 0.00438 + 0.0496) \text{ kmol}} \\ = \frac{10.69 \text{ kg}}{1.045 \text{ kmol}} = 10.23 \text{ kg/kmol coal}$$

Under steady-flow conditions the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$  reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance            | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{500\text{K}}$<br>kJ/kmol |
|----------------------|------------------------------|------------------------------------|------------------------------------|
| O <sub>2</sub>       | 0                            | 8682                               | 14,770                             |
| N <sub>2</sub>       | 0                            | 8669                               | 14,581                             |
| H <sub>2</sub> O (g) | -241,820                     | 9904                               | 16,828                             |
| CO <sub>2</sub>      | -393,520                     | 9364                               | 17,678                             |

Thus,

$$-Q_{\text{out}} = (0.5758)(-393,520 + 17,678 - 9364) + (0.3258)(-241,820 + 16,828 - 9904) \\ + (0.3274)(0 + 14,770 - 8682) + (3.693)(0 + 14,581 - 8669) - 0 \\ = -274,505 \text{ kJ/kmol of fuel}$$

The heat loss per unit mass of the fuel is

$$Q_{\text{out}} = \frac{274,505 \text{ kJ/kmol of fuel}}{10.23 \text{ kg/kmol of fuel}} = 26,833 \text{ kJ/kg fuel}$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$\frac{m_s}{m_f} = \frac{Q_{\text{out}}}{\Delta h_s} = \frac{26,833 \text{ kJ/kg fuel}}{(3214.5 - 852.26) \text{ kJ/kg steam}} = \mathbf{11.36 \text{ kg steam/kg fuel}}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to  $P_i = y_i P_{\text{total}}$ , where  $y_i$  is the mole fraction of component  $i$ . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left( \bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

|                               | $N_i$   | $y_i$   | $\bar{s}_i^\circ(T, 1\text{atm})$ | $R_u \ln(y_i P_m)$ | $N_i \bar{s}_i$              |
|-------------------------------|---------|---------|-----------------------------------|--------------------|------------------------------|
| C                             | 0.5758  | 0.5758  | 5.74                              | -4.589             | 5.95                         |
| H <sub>2</sub>                | 0.3258  | 0.3258  | 130.68                            | -9.324             | 45.61                        |
| O <sub>2</sub>                | 0.0890  | 0.0890  | 205.04                            | -20.11             | 20.04                        |
| N <sub>2</sub>                | 0.00438 | 0.00438 | 191.61                            | -45.15             | 1.04                         |
| O <sub>2</sub>                | 0.9821  | 0.21    | 205.04                            | -12.98             | 214.12                       |
| N <sub>2</sub>                | 3.693   | 0.79    | 191.61                            | -1.960             | 714.85                       |
|                               |         |         |                                   |                    | $S_R = 1001.61 \text{ kJ/K}$ |
| CO <sub>2</sub>               | 0.5758  | 0.1170  | 234.814                           | -17.84             | 145.48                       |
| H <sub>2</sub> O ( <i>g</i> ) | 0.3258  | 0.0662  | 206.413                           | -22.57             | 74.60                        |
| O <sub>2</sub>                | 0.3274  | 0.0665  | 220.589                           | -22.54             | 79.60                        |
| N <sub>2</sub>                | 3.693   | 0.7503  | 206.630                           | -2.388             | 771.90                       |
|                               |         |         |                                   |                    | $S_P = 1071.58 \text{ kJ/K}$ |

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 1071.58 - 1001.61 + \frac{274,505}{298} = 991.1 \text{ kJ/K (per kmol fuel)}$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$\Delta X_{\text{gases}} = -X_{\text{dest}} = -T_0 S_{\text{gen}} = -(298 \text{ K})(991.1 \text{ kJ/K}) = -295,348 \text{ kJ/kmol fuel}$$

Per unit mass basis,

$$\Delta X_{\text{gases}} = \frac{-295,348 \text{ kJ/K}}{10.23 \text{ kg/kmol}} = \mathbf{-28,870 \text{ kJ/kg fuel}}$$

Note that the exergy change is negative since the exergy of combustion gases decreases.

(c) The exergy change of the steam stream is

$$\Delta X_{\text{steam}} = \Delta h - T_0 \Delta s = (3214.5 - 852.26) - (298)(6.7714 - 2.3305) = \mathbf{1039 \text{ kJ/kg steam}}$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$\begin{aligned} X_{\text{dest}} &= - \left( \frac{m_s}{m_f} \Delta X_{\text{steam}} + \Delta X_{\text{gases}} \right) \\ &= -[(11.36 \text{ kg steam/kg fuel})(1039 \text{ kJ/kg steam}) + (-28,870 \text{ kJ/kg fuel})] \\ &= \mathbf{17,070 \text{ kJ/kg fuel}} \end{aligned}$$

**15-121** Octane is burned with stoichiometric amount of air. The maximum work that can be produced is to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** The combustion equation is

The reactants and products are at 25°C and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(16,530) - (8)(-394,360) - (9)(-228,590) \\ &= 5,228,720 \text{ kJ (per kmol of fuel)} \end{aligned}$$

since the  $\bar{g}_f^\circ$  of stable elements at 25°C and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{5,228,720 \text{ kJ/kmol}}{114 \text{ kg/kmol}} = \mathbf{45,870 \text{ kJ/kg fuel}}$$

**15-122** Octane is burned with 100% excess air. The maximum work that can be produced is to be determined.

**Assumptions** 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

**Analysis** The combustion equation is

The reactants and products are at 25°C and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(16,530) - (8)(-394,360) - (9)(-228,590) \\ &= 5,228,720 \text{ kJ (per kmol of fuel)} \end{aligned}$$

since the  $\bar{g}_f^\circ$  of stable elements at 25°C and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{5,228,720 \text{ kJ/kmol}}{114 \text{ kg/kmol}} = \mathbf{45,870 \text{ kJ/kg fuel}}$$

**15-123E** Methane is burned with 100 percent excess air. The combustion is incomplete. The maximum work that can be produced is to be determined.

**Assumptions** **1** Combustion is incomplete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases. **4** Changes in kinetic and potential energies are negligible.

**Analysis** The combustion equation is

The coefficient for  $\text{O}_2$  is determined from its mass balance as

$$4 = 0.9 + (0.5)(0.10) + 1 + x \longrightarrow x = 2.05$$

Substituting,

The reactants and products are at  $77^\circ\text{F}$  and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(-21,860) - (0.9)(-169,680) - (0.10)(-59,010) - (2)(-98,350) \\ &= 333,453 \text{ Btu (per lbmol of fuel)} \end{aligned}$$

since the  $\bar{g}_f^\circ$  of stable elements at  $77^\circ\text{F}$  and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{333,453 \text{ Btu/lbmol}}{16 \text{ lbm/lbmol}} = \mathbf{20,840 \text{ Btu/lbm fuel}}$$

**15-124** A gaseous fuel mixture of 30% propane,  $C_3H_8$ , and 70% butane,  $C_4H_{10}$ , on a volume basis is burned with an air-fuel ratio of 20. The moles of nitrogen in the air supplied to the combustion process, the moles of water formed in the combustion process, and the moles of oxygen in the product gases are to be determined.

**Assumptions** 1 Combustion is complete. 2 The combustion products contain  $CO_2$ ,  $H_2O$ , and  $N_2$  only.

**Properties** The molar masses of C,  $H_2$ ,  $O_2$  and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

**Analysis** The theoretical combustion equation in this case can be written as

where  $a_{th}$  is the stoichiometric coefficient for air. The coefficient  $a_{th}$  and other coefficients are to be determined from the mass balances

$$\text{Carbon balance:} \quad B = 3 \times 0.3 + 4 \times 0.7 = 3.7$$

$$\text{Hydrogen balance:} \quad 2D = 8 \times 0.3 + 10 \times 0.7 = 2D \longrightarrow D = 4.7$$

$$\text{Oxygen balance:} \quad 2a_{th} = 2B + D \longrightarrow 2a_{th} = 2 \times 3.7 + 4.7 \longrightarrow a_{th} = 6.05$$

$$\text{Nitrogen balance:} \quad 3.76a_{th} = F \longrightarrow 3.76 \times 6.05 = F \longrightarrow F = 22.75$$

Then, we write the balanced theoretical reaction equation as

The air-fuel ratio for the theoretical reaction is determined from

$$AF_{th} = \frac{m_{air}}{m_{fuel}} = \frac{(6.05 \times 4.75 \text{ kmol})(29 \text{ kg/kmol})}{(0.3 \times 44 + 0.7 \times 58) \text{ kg}} = 15.47 \text{ kg air/kg fuel}$$

The percent theoretical air is

$$\text{PercentTH}_{air} = \frac{AF_{actual}}{AF_{th}} = \frac{20}{15.47} \times 100 = 129.3\%$$

The moles of nitrogen supplied is

$$N_{N_2} = \frac{\text{PercentTH}_{air}}{100} \times a_{th} \times 3.76 = \frac{129.3}{100} (6.05)(3.76) = \mathbf{29.41 \text{ kmol}} \text{ per kmol fuel}$$

The moles of water formed in the combustion process is

$$N_{H_2O} = D = \mathbf{4.7 \text{ kmol}} \text{ per kmol fuel}$$

The moles of oxygen in the product gases is

$$N_{O_2} = \left( \frac{\text{PercentTH}_{air}}{100} - 1 \right) a_{th} = \left( \frac{129.3}{100} - 1 \right) (6.05) = \mathbf{1.77 \text{ kmol}} \text{ per kmol fuel}$$

**15-125** It is to be shown that the work output of the Carnot engine will be maximum when  $T_p = \sqrt{T_0 T_{af}}$ . It is also to be shown that the maximum work output of the Carnot engine in this case becomes

$$w = CT_{af} \left( 1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}} \right)^2.$$

**Analysis** The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature  $T_{af}$  since the chamber is adiabatic and the fuel is burned completely. The combustion gases experience no change in their chemical composition as they flow through the heat exchanger. Therefore, we can treat the combustion gases as a gas stream with a constant specific heat  $c_p$ . Noting that the heat exchanger involves no work interactions, the energy balance equation for this single-stream steady-flow device can be written as

$$\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C(T_p - T_{af})$$

where  $\dot{Q}$  is the negative of the heat supplied to the heat engine. That is,

$$\dot{Q}_H = -\dot{Q} = \dot{m}C(T_{af} - T_p)$$

Then the work output of the Carnot heat engine can be expressed as

$$\dot{W} = \dot{Q}_H \left( 1 - \frac{T_0}{T_p} \right) = \dot{m}C(T_{af} - T_p) \left( 1 - \frac{T_0}{T_p} \right) \quad (1)$$

Taking the partial derivative of  $\dot{W}$  with respect to  $T_p$  while holding  $T_{af}$  and  $T_0$  constant gives

$$\frac{\partial \dot{W}}{\partial T_p} = 0 \longrightarrow -\dot{m}C \left( 1 - \frac{T_0}{T_p} \right) + \dot{m}C(T_{af} - T_p) \frac{T_0}{T_p^2} = 0$$

Solving for  $T_p$  we obtain

$$T_p = \sqrt{T_0 T_{af}}$$

which the temperature at which the work output of the Carnot engine will be a maximum. The maximum work output is determined by substituting the relation above into Eq. (1),

$$\dot{W} = \dot{m}C(T_{af} - T_p) \left( 1 - \frac{T_0}{T_p} \right) = \dot{m}C(T_{af} - \sqrt{T_0 T_{af}}) \left( 1 - \frac{T_0}{\sqrt{T_0 T_{af}}} \right)$$

It simplifies to

$$\dot{W} = \dot{m}CT_{af} \left( 1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}} \right)^2$$

or

$$w = CT_{af} \left( 1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}} \right)^2$$

which is the desired relation.

**15-126** It is to be shown that the work output of the reversible heat engine operating at the specified conditions is  $\dot{W}_{\text{rev}} = \dot{m}CT_0\left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0}\right)$ . It is also to be shown that the effective flame temperature  $T_e$  of the furnace considered is  $T_e = \frac{T_{\text{af}} - T_0}{\ln(T_{\text{af}}/T_0)}$ .

**Analysis** The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature  $T_{\text{af}}$  since the chamber is adiabatic and the fuel is burned completely. The combustion gases experience no change in their chemical composition as they flow through the heat exchanger. Therefore, we can treat the combustion gases as a gas stream with a constant specific heat  $c_p$ . Also, the work output of the reversible heat engine is equal to the reversible work  $W_{\text{rev}}$  of the heat exchanger as the combustion gases are cooled from  $T_{\text{af}}$  to  $T_0$ . That is,

$$\begin{aligned}\dot{W}_{\text{rev}} &= \dot{m}(h_i - h_e - T_0(s_i - s_e)) \\ &= \dot{m}C\left(T_{\text{af}} - T_0 - T_0\left(C \ln \frac{T_{\text{af}}}{T_0} - R \ln \frac{P_{\text{af}}}{P_0}\right)\right) \\ &= \dot{m}C\left(T_{\text{af}} - T_0 - T_0C \ln \frac{T_{\text{af}}}{T_0}\right)\end{aligned}$$

which can be rearranged as

$$\dot{W}_{\text{rev}} = \dot{m}CT_0\left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0}\right) \quad \text{or} \quad w_{\text{rev}} = CT_0\left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0}\right) \quad (1)$$

which is the desired result.

The effective flame temperature  $T_e$  can be determined from the requirement that a Carnot heat engine which receives the same amount of heat from a heat reservoir at constant temperature  $T_e$  produces the same amount of work. The amount of heat delivered to the heat engine above is

$$\dot{Q}_H = \dot{m}(h_i - h_e) = \dot{m}C(T_{\text{af}} - T_0)$$

A Carnot heat engine which receives this much heat at a constant temperature  $T_e$  will produce work in the amount of

$$\dot{W} = \dot{Q}_H \eta_{\text{th, Carnot}} = \dot{m}C(T_{\text{af}} - T_0)\left(1 - \frac{T_0}{T_e}\right) \quad (2)$$

Setting equations (1) and (2) equal to each other yields

$$\begin{aligned}\dot{m}CT_0\left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0}\right) &= \dot{m}C(T_{\text{af}} - T_0)\left(1 - \frac{T_0}{T_e}\right) \\ T_{\text{af}} - T_0 - T_0 \ln \frac{T_{\text{af}}}{T_0} &= T_{\text{af}} - T_{\text{af}} \frac{T_0}{T_e} - T_0 + T_0 \frac{T_0}{T_e}\end{aligned}$$

Simplifying and solving for  $T_e$ , we obtain

$$T_e = \frac{T_{\text{af}} - T_0}{\ln(T_{\text{af}}/T_0)}$$

which is the desired relation.

**15-127 EES** The effect of the amount of air on the adiabatic flame temperature of liquid octane ( $C_8H_{18}$ ) is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel  $C_nH_m$  entering at  $T_{fuel}$  with Stoichiometric Air at  $T_{air}$ :

Reaction:  $C_xH_yO_z + (y/4 + x-z/2) (Theo\_air/100) (O_2 + 3.76 N_2)$

$\leftrightarrow xCO_2 + (y/2) H_2O + 3.76 (y/4 + x-z/2) (Theo\_air/100) N_2 + (y/4 + x-z/2) (Theo\_air/100 - 1) O_2$

## Fundamentals of Engineering (FE) Exam Problems

**15-133** A fuel is burned with 90 percent theoretical air. This is equivalent to

- (a) 10% excess air                      (b) 90% excess air                      (c) 10% deficiency of air  
 (d) 90% deficiency of air              (e) stoichiometric amount of air

*Answer* (c) 10% deficiency of air

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
air_th=0.9
"air_th=air_access+1"
air_th=1-air_deficiency
```

**15-134** Propane  $C_3H_8$  is burned with 150 percent theoretical air. The air-fuel mass ratio for this combustion process is

- (a) 5.3                      (b) 10.5                      (c) 15.7                      (d) 23.4                      (e) 39.3

*Answer* (d) 23.4

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
n_C=3
n_H=8
m_fuel=n_H*1+n_C*12
a_th=n_C+n_H/4
coeff=1.5 "coeff=1 for theoretical combustion, 1.5 for 50% excess air"
n_O2=coeff*a_th
n_N2=3.76*n_O2
m_air=n_O2*32+n_N2*28
AF=m_air/m_fuel
```

**15-135** One kmol of methane ( $\text{CH}_4$ ) is burned with an unknown amount of air during a combustion process. If the combustion is complete and there are 2 kmol of free  $\text{O}_2$  in the products, the air-fuel mass ratio is

- (a) 34.3                      (b) 17.2                      (c) 19.0                      (d) 14.9                      (e) 12.1

*Answer* (a) 34.3

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
n_C=1
n_H=4
m_fuel=n_H*1+n_C*12
a_th=n_C+n_H/4
(coeff-1)*a_th=2 "O2 balance: Coeff=1 for theoretical combustion, 1.5 for 50% excess air"
n_O2=coeff*a_th
n_N2=3.76*n_O2
m_air=n_O2*32+n_N2*28
AF=m_air/m_fuel
```

"Some Wrong Solutions with Common Mistakes:"

W1\_AF=1/AF "Taking the inverse of AF"

W2\_AF=n\_O2+n\_N2 "Finding air-fuel mole ratio"

W3\_AF=AF/coeff "Ignoring excess air"

**15-136** A fuel is burned steadily in a combustion chamber. The combustion temperature will be the highest except when

- (a) the fuel is preheated.  
 (b) the fuel is burned with a deficiency of air.  
 (c) the air is dry.  
 (d) the combustion chamber is well insulated.  
 (e) the combustion is complete.

*Answer* (b) the fuel is burned with a deficiency of air.

**15-137** An equimolar mixture of carbon dioxide and water vapor at 1 atm and 60°C enter a dehumidifying section where the entire water vapor is condensed and removed from the mixture, and the carbon dioxide leaves at 1 atm and 60°C. The entropy change of carbon dioxide in the dehumidifying section is

- (a)  $-2.8 \text{ kJ/kg}\cdot\text{K}$       (b)  $-0.13 \text{ kJ/kg}\cdot\text{K}$       (c) 0      (d)  $0.13 \text{ kJ/kg}\cdot\text{K}$       (e)  $2.8 \text{ kJ/kg}\cdot\text{K}$

*Answer* (b)  $-0.13 \text{ kJ/kg}\cdot\text{K}$

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Cp_CO2=0.846
R_CO2=0.1889
T1=60+273 "K"
T2=T1
P1= 1 "atm"
P2=1 "atm"
y1_CO2=0.5; P1_CO2=y1_CO2*P1
y2_CO2=1; P2_CO2=y2_CO2*P2
Ds_CO2=Cp_CO2*ln(T2/T1)-R_CO2*ln(P2_CO2/P1_CO2)
```

"Some Wrong Solutions with Common Mistakes:"

W1\_Ds=0 "Assuming no entropy change"

W2\_Ds=Cp\_CO2\*ln(T2/T1)-R\_CO2\*ln(P1\_CO2/P2\_CO2) "Using pressure fractions backwards"

**15-138** Methane ( $\text{CH}_4$ ) is burned completely with 80% excess air during a steady-flow combustion process. If both the reactants and the products are maintained at 25°C and 1 atm and the water in the products exists in the liquid form, the heat transfer from the combustion chamber per unit mass of methane is

- (a) 890 MJ/kg      (b) 802 MJ/kg      (c) 75 MJ/kg      (d) 56 MJ/kg      (e) 50 MJ/kg

*Answer* (d) 56 MJ/kg

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T= 25 "C"
P=1 "atm"
EXCESS=0.8
"Heat transfer in this case is the HHV at room temperature,"
HHV_CH4 =55.53 "MJ/kg"
LHV_CH4 =50.05 "MJ/kg"
```

"Some Wrong Solutions with Common Mistakes:"

W1\_Q=LHV\_CH4 "Assuming lower heating value"

W2\_Q=EXCESS\*hHV\_CH4 "Assuming Q to be proportional to excess air"

**15-139** The higher heating value of a hydrocarbon fuel  $C_nH_m$  with  $m = 8$  is given to be 1560 MJ/kmol of fuel. Then its lower heating value is

- (a) 1384 MJ/kmol    (b) 1208 MJ/kmol    (c) 1402 MJ/kmol    (d) 1540 MJ/kmol    (e) 1550 MJ/kmol

*Answer* (a) 1384 MJ/kmol

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
HHV=1560 "MJ/kmol fuel"
h_fg=2.4423 "MJ/kg, Enthalpy of vaporization of water at 25C"
n_H=8
n_water=n_H/2
m_water=n_water*18
LHV=HHV-h_fg*m_water
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_LHV=HHV - h_fg*n_water "Using mole numbers instead of mass"
W2_LHV= HHV - h_fg*m_water*2 "Taking mole numbers of H2O to be m instead of m/2"
W3_LHV= HHV - h_fg*n_water*2 "Taking mole numbers of H2O to be m instead of m/2, and
using mole numbers"
```

**15-140** Acetylene gas ( $C_2H_2$ ) is burned completely during a steady-flow combustion process. The fuel and the air enter the combustion chamber at 25°C, and the products leave at 1500 K. If the enthalpy of the products relative to the standard reference state is -404 MJ/kmol of fuel, the heat transfer from the combustion chamber is

- (a) 177 MJ/kmol    (b) 227 MJ/kmol    (c) 404 MJ/kmol    (d) 631 MJ/kmol    (e) 751 MJ/kmol

*Answer* (d) 631 MJ/kmol

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
hf_fuel=226730/1000 "MJ/kmol fuel"
H_prod=-404 "MJ/kmol fuel"
H_react=hf_fuel
Q_out=H_react-H_prod
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Qout= -H_prod "Taking Qout to be H_prod"
W2_Qout= H_react+H_prod "Adding enthalpies instead of subtracting them"
```

**15-141** Benzene gas ( $C_6H_6$ ) is burned with 90 percent theoretical air during a steady-flow combustion process. The mole fraction of the CO in the products is

- (a) 1.6%                      (b) 4.4%                      (c) 2.5%                      (d) 10.0%                      (e) 16.7%

*Answer* (b) 4.4%

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
n_C=6
n_H=6
a_th=n_C+n_H/4
coeff=0.90 "coeff=1 for theoretical combustion, 1.5 for 50% excess air"
"Assuming all the H burns to H2O, the combustion equation is
  C6H6+coeff*a_th(O2+3.76N2)----- (n_CO2) CO2+(n_CO)CO+(n_H2O) H2O+(n_N2) N2"
n_O2=coeff*a_th
n_N2=3.76*n_O2
n_H2O=n_H/2
n_CO2+n_CO=n_C
2*n_CO2+n_CO+n_H2O=2*n_O2 "Oxygen balance"
n_prod=n_CO2+n_CO+n_H2O+n_N2 "Total mole numbers of product gases"
y_CO=n_CO/n_prod "mole fraction of CO in product gases"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_yCO=n_CO/n1_prod; n1_prod=n_CO2+n_CO+n_H2O "Not including N2 in n_prod"
W2_yCO=(n_CO2+n_CO)/n_prod "Using both CO and CO2 in calculations"
```

**15-142** A fuel is burned during a steady-flow combustion process. Heat is lost to the surroundings at 300 K at a rate of 1120 kW. The entropy of the reactants entering per unit time is 17 kW/K and that of the products is 15 kW/K. The total rate of exergy destruction during this combustion process is

- (a) 520 kW                      (b) 600 kW                      (c) 1120 kW                      (d) 340 kW                      (e) 739 kW

*Answer* (a) 520 kW

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
To=300 "K"
Q_out=1120 "kW"
S_react=17 "kW/K"
S_prod= 15 "kW/K"
S_react-S_prod-Q_out/To+S_gen=0 "Entropy balance for steady state operation, Sin-
Sout+Sgen=0"
X_dest=To*S_gen
```

"Some Wrong Solutions with Common Mistakes:"

W1\_Xdest=S\_gen "Taking Sgen as exergy destruction"

W2\_Xdest=To\*S\_gen1; S\_react-S\_prod-S\_gen1=0 "Ignoring Q\_out/To"

#### 15-143 ... 15-147 Design and Essay Problems

**15-143** A certain industrial process generates a liquid solution of ethanol and water as the waste product. The solution is to be burned using methane. A combustion process is to be developed to accomplish this incineration process with minimum amount of methane.

**Analysis** The mass flow rate of the liquid ethanol-water solution is given to be 10 kg/s. Considering that the mass fraction of ethanol in the solution is 0.2,

$$\begin{aligned}\dot{m}_{\text{ethanol}} &= (0.2)(10 \text{ kg/s}) = 2 \text{ kg/s} \\ \dot{m}_{\text{water}} &= (0.8)(10 \text{ kg/s}) = 8 \text{ kg/s}\end{aligned}$$

Noting that the molar masses  $M_{\text{ethanol}} = 46$  and  $M_{\text{water}} = 18$  kg/kmol and that mole numbers  $N = m/M$ , the mole flow rates become

$$\begin{aligned}\dot{N}_{\text{ethanol}} &= \frac{\dot{m}_{\text{ethanol}}}{M_{\text{ethanol}}} = \frac{2 \text{ kg/s}}{46 \text{ kg/kmol}} = 0.04348 \text{ kmol/s} \\ \dot{N}_{\text{water}} &= \frac{\dot{m}_{\text{water}}}{M_{\text{water}}} = \frac{8 \text{ kg/s}}{18 \text{ kg/kmol}} = 0.44444 \text{ kmol/s}\end{aligned}$$

Note that

$$\frac{\dot{N}_{\text{water}}}{\dot{N}_{\text{ethanol}}} = \frac{0.44444}{0.04348} = 10.222 \text{ kmol H}_2\text{O/kmol C}_2\text{H}_5\text{OH}$$

That is, 10.222 moles of liquid water is present in the solution for each mole of ethanol.

Assuming complete combustion, the combustion equation of  $\text{C}_2\text{H}_5\text{OH}(\ell)$  with stoichiometric amount of air is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$1 + 2a_{\text{th}} = 4 + 3 \longrightarrow a_{\text{th}} = 3$$

Thus,

Noting that 10.222 kmol of liquid water accompanies each kmol of ethanol, the actual combustion equation can be written as

The heat transfer for this combustion process is determined from the steady-flow energy balance equation with  $W = 0$ ,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . We assume all the reactants to enter the combustion chamber at the standard reference temperature of 25°C. Furthermore, we assume the products to leave the combustion chamber at 1400 K which is a little over the required temperature of 1100°C. From the tables,

| Substance                             | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{1400 \text{ K}}$<br>kJ/kmol |
|---------------------------------------|------------------------------|--------------------------------------|---------------------------------------|
| $\text{C}_2\text{H}_5\text{OH}(\ell)$ | -277,690                     | ---                                  | ---                                   |
| $\text{CH}_4$                         | -74,850                      | ---                                  | ---                                   |
| $\text{O}_2$                          | 0                            | 8682                                 | 45,648                                |
| $\text{N}_2$                          | 0                            | 8669                                 | 43,605                                |
| $\text{H}_2\text{O}(g)$               | -241,820                     | 9904                                 | 53,351                                |
| $\text{H}_2\text{O}(\ell)$            | -285,830                     | ---                                  | ---                                   |
| $\text{CO}_2$                         | -393,520                     | 9364                                 | 65,271                                |

Thus,

$$\begin{aligned} Q &= (2)(-393,520 + 65,271 - 9364) + (3)(-241,820 + 53,351 - 9904) \\ &\quad + (11.28)(0 + 43,605 - 8669) - (1)(-277,690) - 0 - 0 \\ &\quad + (10.222)(-241,820 + 53,351 - 9904) - (10.222)(-285,830) \\ &= 295,409 \text{ kJ/kmol of } \text{C}_2\text{H}_5\text{OH} \end{aligned}$$

The positive sign indicates that 295,409 kJ of heat must be supplied to the combustion chamber from another source (such as burning methane) to ensure that the combustion products will leave at the desired temperature of 1400 K. Then the rate of heat transfer required for a mole flow rate of 0.04348 kmol  $\text{C}_2\text{H}_5\text{OH/s}$  becomes

$$\dot{Q} = \dot{N}Q = (0.04348 \text{ kmol/s})(295,409 \text{ kJ/kmol}) = 12,844 \text{ kJ/s}$$

Assuming complete combustion, the combustion equation of  $\text{CH}_4(g)$  with stoichiometric amount of air is

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

Thus,

$$a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

The heat transfer for this combustion process is determined from the steady-flow energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  equation as shown above under the same assumptions and using the same mini table:

$$\begin{aligned} Q &= (1)(-393,520 + 65,271 - 9364) + (2)(-241,820 + 53,351 - 9904) \\ &\quad + (7.52)(0 + 43,605 - 8669) - (1)(-74,850) - 0 - 0 \\ &= -396,790 \text{ kJ/kmol of } \text{CH}_4 \end{aligned}$$

That is, 396,790 kJ of heat is supplied to the combustion chamber for each kmol of methane burned. To supply heat at the required rate of 12,844 kJ/s, we must burn methane at a rate of

$$\dot{N}_{\text{CH}_4} = \frac{\dot{Q}}{Q} = \frac{12,844 \text{ kJ/s}}{396,790 \text{ kJ/kmol}} = 0.03237 \text{ kmolCH}_4/\text{s}$$

or,

$$\dot{m}_{\text{CH}_4} = M_{\text{CH}_4} \dot{N}_{\text{CH}_4} = (16 \text{ kg/kmol})(0.03237 \text{ kmolCH}_4/\text{s}) = \mathbf{0.5179 \text{ kg/s}}$$

Therefore, we must supply methane to the combustion chamber at a minimum rate 0.5179 kg/s in order to maintain the temperature of the combustion chamber above 1400 K.

# Chapter 16

## CHEMICAL AND PHASE EQUILIBRIUM

### The $K_p$ and Equilibrium Composition of Ideal Gases

**16-1C** Because when a reacting system involves heat transfer, the increase-in-entropy principle relation requires a knowledge of heat transfer between the system and its surroundings, which is impractical. The equilibrium criteria can be expressed in terms of the properties alone when the Gibbs function is used.

**16-2C** No, the wooden table is NOT in chemical equilibrium with the air. With proper catalyst, it will reach with the oxygen in the air and burn.

**16-3C** They are

$$K_p = \frac{P_C^{\nu_C} P_D^{\nu_D}}{P_A^{\nu_A} P_B^{\nu_B}}, \quad K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{and} \quad K_p = \frac{N_C^{\nu_C} N_D^{\nu_D}}{N_A^{\nu_A} N_B^{\nu_B}} \left( \frac{P}{N_{\text{total}}} \right)^{\Delta \nu}$$

where  $\Delta \nu = \nu_C + \nu_D - \nu_A - \nu_B$ . The first relation is useful in partial pressure calculations, the second in determining the  $K_p$  from gibbs functions, and the last one in equilibrium composition calculations.

**16-4C (a)** This reaction is the reverse of the known CO reaction. The equilibrium constant is then

$$1/K_p$$

**(b)** This reaction is the reverse of the known CO reaction at a different pressure. Since pressure has no effect on the equilibrium constant,

$$1/K_p$$

**(c)** This reaction is the same as the known CO reaction multiplied by 2. The equilibrium constant is then

$$K_p^2$$

**(d)** This is the same as reaction (c) occurring at a different pressure. Since pressure has no effect on the equilibrium constant,

$$K_p^2$$

**16-5C** (a) This reaction is the reverse of the known  $\text{H}_2\text{O}$  reaction. The equilibrium constant is then

$$1/K_p$$

(b) This reaction is the reverse of the known  $\text{H}_2\text{O}$  reaction at a different pressure. Since pressure has no effect on the equilibrium constant,

$$1/K_p$$

(c) This reaction is the same as the known  $\text{H}_2\text{O}$  reaction multiplied by 3. The equilibrium constant is then

$$K_p^3$$

(d) This is the same as reaction (c) occurring at a different pressure. Since pressure has no effect on the equilibrium constant,

$$K_p^3$$

**16-6C** (a) No, because  $K_p$  depends on temperature only.

(b) In general, the total mixture pressure affects the mixture composition. The equilibrium constant for the reaction  $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$  can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

The value of the exponent in this case is  $2 - 1 - 1 = 0$ . Therefore, changing the total mixture pressure will have no effect on the number of moles of  $\text{N}_2$ ,  $\text{O}_2$  and  $\text{NO}$ .

**16-7C** (a) The equilibrium constant for the reaction  $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$  can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

Judging from the values in Table A-28, the  $K_p$  value for this reaction decreases as temperature increases. That is, the indicated reaction will be less complete at higher temperatures. Therefore, the number of moles of  $\text{CO}_2$  will decrease and the number moles of  $\text{CO}$  and  $\text{O}_2$  will increase as the temperature increases.

(b) The value of the exponent in this case is  $1 - 1 - 0.5 = -0.5$ , which is negative. Thus as the pressure increases, the term in the brackets will decrease. The value of  $K_p$  depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products ( $\text{CO}_2$ ) must increase, and the number of moles of the reactants ( $\text{CO}$ ,  $\text{O}_2$ ) must decrease.

**16-8C** (a) The equilibrium constant for the reaction  $\text{N}_2 \rightleftharpoons 2\text{N}$  can be expressed as

$$K_p = \frac{N_{\text{N}}^{\nu_{\text{N}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{N}} - \nu_{\text{N}_2})}$$

Judging from the values in Table A-28, the  $K_p$  value for this reaction increases as the temperature increases. That is, the indicated reaction will be more complete at higher temperatures. Therefore, the number of moles of N will increase and the number moles of  $\text{N}_2$  will decrease as the temperature increases.

(b) The value of the exponent in this case is  $2-1 = 1$ , which is positive. Thus as the pressure increases, the term in the brackets also increases. The value of  $K_p$  depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products (N) must decrease, and the number of moles of the reactants ( $\text{N}_2$ ) must increase.

**16-9C** The equilibrium constant for the reaction  $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$  can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

Adding more  $\text{N}_2$  (an inert gas) at constant temperature and pressure will increase  $N_{\text{total}}$  but will have no direct effect on other terms. Then to keep the equation balanced, the number of moles of the products ( $\text{CO}_2$ ) must increase, and the number of moles of the reactants ( $\text{CO}$ ,  $\text{O}_2$ ) must decrease.

**16-10C** The values of the equilibrium constants for each dissociation reaction at 3000 K are, from Table A-28,

$$\text{N}_2 \rightleftharpoons 2\text{N} \rightleftharpoons \ln K_p = -22.359$$

$$\text{H}_2 \rightleftharpoons 2\text{H} \rightleftharpoons \ln K_p = -3.685 \quad (\text{greater than } -22.359)$$

Thus  $\text{H}_2$  is more likely to dissociate than  $\text{N}_2$ .

**16-11** The mole fractions of the constituents of an ideal gas mixture is given. The Gibbs function of the CO in this mixture at the given mixture pressure and temperature is to be determined.

**Analysis** From Tables A-21 and A-26, at 1 atm pressure,

$$\begin{aligned}\bar{g}^*(800 \text{ K}, 1 \text{ atm}) &= \bar{g}_f^\circ + \Delta[\bar{h}(T) - T\bar{s}^\circ(T)] \\ &= -137,150 + (23,844 - 800 \times 227.162) - (8669 - 298 \times 197.543) \\ &= -244,837 \text{ kJ/kmol}\end{aligned}$$

The partial pressure of CO is

$$P_{\text{CO}} = y_{\text{CO}}P = (0.30)(10 \text{ atm}) = 3 \text{ atm}$$

The Gibbs function of CO at 800 K and 3 atm is

$$\begin{aligned}\bar{g}(800 \text{ K}, 3 \text{ atm}) &= \bar{g}^*(800 \text{ K}, 1 \text{ atm}) + R_u T \ln P_{\text{CO}} \\ &= -244,837 \text{ kJ/kmol} + (8.314 \text{ kJ/kmol})(800 \text{ K})\ln(3 \text{ atm}) \\ &= \mathbf{-237,530 \text{ kJ/kmol}}\end{aligned}$$

10% CO<sub>2</sub>  
60% H<sub>2</sub>O  
30% CO  
10 atm  
800 K

**16-12** The partial pressures of the constituents of an ideal gas mixture is given. The Gibbs function of the nitrogen in this mixture at the given mixture pressure and temperature is to be determined.

**Analysis** The partial pressure of nitrogen is

$$P_{\text{N}_2} = 130 \text{ kPa} = (130 / 101.325) = 1.283 \text{ atm}$$

The Gibbs function of nitrogen at 298 K and 3 atm is

$$\begin{aligned}\bar{g}(298 \text{ K}, 1.283 \text{ atm}) &= \bar{g}^*(298 \text{ K}, 1 \text{ atm}) + R_u T \ln P_{\text{N}_2} \\ &= 0 + (8.314 \text{ kJ/kmol})(298 \text{ K})\ln(1.283 \text{ atm}) \\ &= \mathbf{617.4 \text{ kJ/kmol}}\end{aligned}$$

N<sub>2</sub>, CO<sub>2</sub>, NO  
  
P<sub>N<sub>2</sub></sub> = 130 kPa  
298 K

**16-13E** The equilibrium constant of the reaction  $\text{H}_2\text{O} \leftrightarrow \text{H}_2 + \frac{1}{2}\text{O}_2$  is to be determined using Gibbs function.

**Analysis** (a) The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 1440 R,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{1440} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{1440} - \bar{h}_{537}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{1440} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &= 1 \times (0 + 9956.9 - 3640.3 - 1440 \times 38.079) \\ &\quad + 0.5 \times (0 + 10,532.0 - 3725.1 - 1440 \times 56.326) \\ &\quad - 1 \times (-104,040 + 11,933.4 - 4258 - 1440 \times 53.428) \\ &= 87,632 \text{ Btu/lbmol} \end{aligned}$$

1440 R

Substituting,

$$\ln K_p = -(87,632 \text{ Btu/lbmol}) / [(1.986 \text{ Btu/lbmol} \cdot \text{R})(1440 \text{ R})] = \mathbf{-30.64}$$

or

$$K_p = \mathbf{4.93 \times 10^{-14}} \quad (\text{Table A-28: } \ln K_p = -34.97 \text{ by interpolation})$$

At 3960 R,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{3960} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{3960} - \bar{h}_{537}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{3960} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &= 1 \times (0 + 29,370.5 - 3640.3 - 3960 \times 45.765) \\ &\quad + 0.5 \times (0 + 32,441 - 3725.1 - 3960 \times 65.032) \\ &\quad - 1 \times (-104,040 + 39,989 - 4258 - 3960 \times 64.402) \\ &= 53,436 \text{ Btu/lbmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(53,436 \text{ Btu/lbmol}) / [(1.986 \text{ Btu/lbmol} \cdot \text{R})(3960 \text{ R})] = \mathbf{-6.79}$$

or

$$K_p = \mathbf{1.125 \times 10^{-3}} \quad (\text{Table A-28: } \ln K_p = -6.768)$$

**16-14** The reaction  $2\text{H}_2\text{O} \Leftrightarrow 2\text{H}_2 + \text{O}_2$  is considered. The mole fractions of the hydrogen and oxygen produced when this reaction occurs at 4000 K and 10 kPa are to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{H}_2$ , and  $\text{O}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $2\text{H}_2\text{O} \Leftrightarrow 2\text{H}_2 + \text{O}_2$  (thus  $\nu_{\text{H}_2\text{O}} = 2$ ,  $\nu_{\text{H}_2} = 2$ , and  $\nu_{\text{O}_2} = 1$ )

Actual:  $2\text{H}_2\text{O} \longrightarrow \underbrace{x\text{H}_2\text{O}}_{\text{react.}} + \underbrace{y\text{H}_2 + z\text{O}_2}_{\text{products}}$

H balance:  $4 = 2x + 2y \longrightarrow y = 2 - x$

O balance:  $2 = x + 2z \longrightarrow z = 1 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z = 3 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

From Table A-28,  $\ln K_p = -0.542$  at 4000 K. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 0.542) = 0.3382$$

Substituting,

$$0.3382 = \frac{(2-x)^2(1-0.5x)}{x^2} \left( \frac{10/101.325}{3-0.5x} \right)^{2+1-2}$$

Solving for  $x$ ,

$$x = 0.4446$$

Then,

$$y = 2 - x = 1.555$$

$$z = 1 - 0.5x = 0.7777$$

Therefore, the equilibrium composition of the mixture at 4000 K and 10 kPa is

$$0.4446 \text{H}_2\text{O} + 1.555 \text{H}_2 + 0.7777 \text{O}_2$$

The mole fractions of hydrogen and oxygen produced are

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{1.555}{3 - 0.5 \times 0.4446} = \frac{1.555}{2.778} = \mathbf{0.560}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{total}}} = \frac{0.7777}{2.778} = \mathbf{0.280}$$

$2\text{H}_2\text{O}$   
 4000 K  
 10 kPa

**16-15** The reaction  $2\text{H}_2\text{O} \Leftrightarrow 2\text{H}_2 + \text{O}_2$  is considered. The mole fractions of hydrogen gas produced is to be determined at 100 kPa and compared to that at 10 kPa.

**Assumptions 1** The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{H}_2$ , and  $\text{O}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $2\text{H}_2\text{O} \Leftrightarrow 2\text{H}_2 + \text{O}_2$  (thus  $\nu_{\text{H}_2\text{O}} = 2$ ,  $\nu_{\text{H}_2} = 2$ , and  $\nu_{\text{O}_2} = 1$ )

Actual:  $2\text{H}_2\text{O} \longrightarrow \underbrace{x\text{H}_2\text{O}}_{\text{react.}} + \underbrace{y\text{H}_2 + z\text{O}_2}_{\text{products}}$

H balance:  $4 = 2x + 2y \longrightarrow y = 2 - x$

O balance:  $2 = x + 2z \longrightarrow z = 1 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z = 3 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

From Table A-28,  $\ln K_p = -0.542$  at 4000 K. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 0.542) = 0.3382$$

Substituting,

$$0.3382 = \frac{(2-x)^2 (1-0.5x)}{x^2} \left( \frac{100/101.325}{3-0.5x} \right)^{2+1-2}$$

Solving for  $x$ ,

$$x = 0.8870$$

Then,

$$y = 2 - x = 1.113$$

$$z = 1 - 0.5x = 0.5565$$

Therefore, the equilibrium composition of the mixture at 4000 K and 100 kPa is

$$0.8870 \text{H}_2\text{O} + 1.113 \text{H}_2 + 0.5565 \text{O}_2$$

That is, there are **1.113 kmol** of hydrogen gas. The mole number of hydrogen at 10 kPa reaction pressure was obtained in the previous problem to be **1.555 kmol**. Therefore, the amount of hydrogen gas produced has decreased.

$2\text{H}_2\text{O}$   
 4000 K  
 100 kPa

**16-16** The reaction  $2\text{H}_2\text{O} \rightleftharpoons 2\text{H}_2 + \text{O}_2$  is considered. The mole number of hydrogen gas produced is to be determined if inert nitrogen is mixed with water vapor is to be determined and compared to the case with no inert nitrogen.

**Assumptions** 1 The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{H}_2$ ,  $\text{O}_2$ , and  $\text{N}_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $2\text{H}_2\text{O} \rightleftharpoons 2\text{H}_2 + \text{O}_2$  (thus  $\nu_{\text{H}_2\text{O}} = 2$ ,  $\nu_{\text{H}_2} = 2$ , and  $\nu_{\text{O}_2} = 1$ )

Actual:  $2\text{H}_2\text{O} + 0.5\text{N}_2 \longrightarrow \underbrace{x\text{H}_2\text{O}}_{\text{react.}} + \underbrace{y\text{H}_2 + z\text{O}_2}_{\text{products}} + \underbrace{0.5\text{N}_2}_{\text{inert}}$

H balance:  $4 = 2x + 2y \longrightarrow y = 2 - x$

O balance:  $2 = x + 2z \longrightarrow z = 1 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z + 0.5 = 3.5 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

From Table A-28,  $\ln K_p = -0.542$  at 4000 K. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 0.542) = 0.3382$$

Substituting,

$$0.3382 = \frac{(2-x)^2 (1-0.5x)}{x^2} \left( \frac{10/101.325}{3.5-0.5x} \right)^{2+1-2}$$

Solving for  $x$ ,

$$x = 0.4187$$

Then,

$$y = 2 - x = 1.581$$

$$z = 1 - 0.5x = 0.7907$$

Therefore, the equilibrium composition of the mixture at 4000 K and 10 kPa is

That is, there are **1.581 kmol** of hydrogen gas. The mole number of hydrogen without inert nitrogen case was obtained in Prob. 16-14 to be **1.555 kmol**. Therefore, the amount of hydrogen gas produced has increased.

$2\text{H}_2\text{O}, 0.5\text{N}_2$   
 4000 K  
 10 kPa

**16-17E** The temperature at which 15 percent of diatomic oxygen dissociates into monatomic oxygen at two pressures is to be determined.

**Assumptions** **1** The equilibrium composition consists of  $O_2$  and  $O$ . **2** The constituents of the mixture are ideal gases.

**Analysis** (a) The stoichiometric and actual reactions can be written as

Stoichiometric:  $O_2 \leftrightarrow 2O$  (thus  $\nu_{O_2} = 1$  and  $\nu_O = 2$ )

Actual:  $O_2 \leftrightarrow \underbrace{0.85O_2}_{\text{react.}} + \underbrace{0.3O}_{\text{prod.}}$

The equilibrium constant  $K_p$  can be determined from

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}} = \frac{0.3^2}{0.85} \left( \frac{3/14.696}{0.85 + 0.3} \right)^{2-1} = 0.01880$$

and

$$\ln K_p = -3.974$$

From Table A-28, the temperature corresponding to this  $\ln K_p$  value is

$$T = 3060 \text{ K} = \mathbf{5508 \text{ R}}$$

(b) At 100 psia,

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}} = \frac{0.3^2}{0.85} \left( \frac{100/14.696}{0.85 + 0.3} \right)^{2-1} = 0.6265$$

$$\ln K_p = -0.4676$$

From Table A-28, the temperature corresponding to this  $\ln K_p$  value is

$$T = 3701 \text{ K} = \mathbf{6662 \text{ R}}$$

**16-18** The dissociation reaction  $\text{CO}_2 \Leftrightarrow \text{CO} + \text{O}$  is considered. The composition of the products at given pressure and temperature is to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{CO}$ , and  $\text{O}$ . **2** The constituents of the mixture are ideal gases.

**Analysis** For the stoichiometric reaction  $\text{CO}_2 \Leftrightarrow \text{CO} + \frac{1}{2}\text{O}_2$ , from Table A-28, at 2500 K

$$\ln K_p = -3.331$$

For the oxygen dissociation reaction  $0.5\text{O}_2 \Leftrightarrow \text{O}$ , from Table A-28, at 2500 K,

$$\ln K_p = -8.509 / 2 = -4.255$$

For the desired stoichiometric reaction  $\text{CO}_2 \Leftrightarrow \text{CO} + \text{O}$  (thus  $\nu_{\text{CO}_2} = 1$ ,  $\nu_{\text{CO}} = 1$  and  $\nu_{\text{O}} = 1$ ),

$$\ln K_p = -3.331 - 4.255 = -7.586$$

and

$$K_p = \exp(-7.586) = 0.0005075$$

Actual:  $\text{CO}_2 \longrightarrow \underbrace{x\text{CO}_2}_{\text{react.}} + \underbrace{y\text{CO} + z\text{O}}_{\text{products}}$

C balance:  $1 = x + y \longrightarrow y = 1 - x$

O balance:  $2 = 2x + y + z \longrightarrow z = 1 - x$

Total number of moles:  $N_{\text{total}} = x + y + z = 2 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CO}} + \nu_{\text{O}} - \nu_{\text{CO}_2}}$$

Substituting,

$$0.0005075 = \frac{(1-x)(1-x)}{x} \left( \frac{1}{2-x} \right)^{1+1-1}$$

Solving for  $x$ ,

$$x = 0.9775$$

Then,

$$y = 1 - x = 0.0225$$

$$z = 1 - x = 0.0225$$

Therefore, the equilibrium composition of the mixture at 2500 K and 1 atm is

$$\mathbf{0.9775 \text{ CO}_2 + 0.0225 \text{ CO} + 0.0225 \text{ O}}$$

**16-19** The dissociation reaction  $\text{CO}_2 \Leftrightarrow \text{CO} + \text{O}$  is considered. The composition of the products at given pressure and temperature is to be determined when nitrogen is added to carbon dioxide.

**Assumptions 1** The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}$ , and  $\text{N}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** For the stoichiometric reaction  $\text{CO}_2 \Leftrightarrow \text{CO} + \frac{1}{2}\text{O}_2$ , from Table A-28, at 2500 K

$$\ln K_p = -3.331$$

For the oxygen dissociation reaction  $0.5\text{O}_2 \Leftrightarrow \text{O}$ , from Table A-28, at 2500 K,

$$\ln K_p = -8.509 / 2 = -4.255$$

For the desired stoichiometric reaction  $\text{CO}_2 \Leftrightarrow \text{CO} + \text{O}$  (thus  $\nu_{\text{CO}_2} = 1$ ,  $\nu_{\text{CO}} = 1$  and  $\nu_{\text{O}} = 1$ ),

$$\ln K_p = -3.331 - 4.255 = -7.586$$

and

$$K_p = \exp(-7.586) = 0.0005075$$

$\text{CO}_2, 3\text{N}_2$   
2500 K  
1 atm

C balance:  $1 = x + y \longrightarrow y = 1 - x$

O balance:  $2 = 2x + y + z \longrightarrow z = 1 - x$

Total number of moles:  $N_{\text{total}} = x + y + z + 3 = 5 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CO}} + \nu_{\text{O}} - \nu_{\text{CO}_2}}$$

Substituting,

$$0.0005075 = \frac{(1-x)(1-x)}{x} \left( \frac{1}{5-x} \right)^{1+1-1}$$

Solving for  $x$ ,

$$x = 0.9557$$

Then,

$$y = 1 - x = 0.0443$$

$$z = 1 - x = 0.0443$$

Therefore, the equilibrium composition of the mixture at 2500 K and 1 atm is

**16-20** It is to be shown that as long as the extent of the reaction,  $\alpha$ , for the disassociation reaction  $X_2 \Leftrightarrow 2X$  is smaller than one,  $\alpha$  is given by  $\alpha = \sqrt{\frac{K_P}{4 + K_P}}$

**Assumptions** The reaction occurs at the reference temperature.

**Analysis** The stoichiometric and actual reactions can be written as

Stoichiometric:  $X_2 \Leftrightarrow 2X$  (thus  $\nu_{X_2} = 1$  and  $\nu_X = 2$ )

Actual:  $X_2 \Leftrightarrow \underbrace{(1-\alpha)X_2}_{\text{react.}} + \underbrace{2\alpha X}_{\text{prod.}}$

The equilibrium constant  $K_P$  is given by

$$K_P = \frac{N_X^{\nu_X}}{N_{X_2}^{\nu_{X_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_X - \nu_{X_2}} = \frac{(2\alpha)^2}{(1-\alpha)} \left( \frac{1}{\alpha+1} \right)^{2-1} = \frac{4\alpha^2}{(1-\alpha)(1+\alpha)}$$

Solving this expression for  $\alpha$  gives

$$\alpha = \sqrt{\frac{K_P}{4 + K_P}}$$

**16-21** A gaseous mixture consisting of methane and nitrogen is heated. The equilibrium composition (by mole fraction) of the resulting mixture is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CH}_4$ , C,  $\text{H}_2$ , and  $\text{N}_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{CH}_4 \Leftrightarrow \text{C} + 2\text{H}_2$  (thus  $\nu_{\text{CH}_4} = 1$ ,  $\nu_{\text{C}} = 1$ , and  $\nu_{\text{H}_2} = 2$ )

Actual:  $\text{CH}_4 + \text{N}_2 \longrightarrow \underbrace{x\text{CH}_4}_{\text{react.}} + \underbrace{y\text{C} + z\text{H}_2}_{\text{products}} + \underbrace{\text{N}_2}_{\text{inert}}$

C balance:  $1 = x + y \longrightarrow y = 1 - x$

H balance:  $4 = 4x + 2z \longrightarrow z = 2 - 2x$

Total number of moles:  $N_{\text{total}} = x + y + z + 1 = 4 - 2x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CH}_4}^{\nu_{\text{CH}_4}}}{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{H}_2}^{\nu_{\text{H}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CH}_4} - \nu_{\text{C}} - \nu_{\text{H}_2}}$$

From the problem statement at 1000 K,  $\ln K_p = 2.328$ . Then,

$$K_p = \exp(2.328) = 10.257$$

For the reverse reaction that we consider,

$$K_p = 1/10.257 = 0.09749$$

Substituting,

$$0.09749 = \frac{x}{(1-x)(2-2x)^2} \left( \frac{1}{4-2x} \right)^{1-1-2}$$

Solving for  $x$ ,

$$x = 0.02325$$

Then,

$$y = 1 - x = 0.9768$$

$$z = 2 - 2x = 1.9535$$

Therefore, the equilibrium composition of the mixture at 1000 K and 1 atm is

$$0.02325 \text{ CH}_4 + 0.9768 \text{ C} + 1.9535 \text{ H}_2 + 1 \text{ N}_2$$

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_{\text{total}}} = \frac{0.02325}{4 - 2 \times 0.02325} = \frac{0.02325}{3.954} = \mathbf{0.0059}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_{\text{total}}} = \frac{0.9768}{3.954} = \mathbf{0.2470}$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{1.9535}{3.954} = \mathbf{0.4941}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{total}}} = \frac{1}{3.954} = \mathbf{0.2529}$$

$\text{CH}_4, \text{N}_2$   
1000 K  
1 atm

**16-22** The reaction  $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$  is considered. The equilibrium mole fraction of NO 1000 K and 1 atm is to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{N}_2$ ,  $\text{O}_2$ , and NO. **2** The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$  (thus  $\nu_{\text{N}_2} = 1$ ,  $\nu_{\text{O}_2} = 1$ , and  $\nu_{\text{NO}} = 2$ )

Actual:  $\text{N}_2 + \text{O}_2 \longrightarrow \underbrace{x\text{N}_2 + y\text{O}_2}_{\text{react.}} + \underbrace{z\text{NO}}_{\text{products}}$

N balance:  $2 = 2x + z \longrightarrow z = 2 - 2x$

O balance:  $2 = 2y + z \longrightarrow y = x$

Total number of moles:  $N_{\text{total}} = x + y + z = 2$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 1000 K,  $\ln K_p = -9.388$ . Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 9.388) = 7.009 \times 10^{-9}$$

Substituting,

$$7.009 \times 10^{-9} = \frac{(2-2x)^2}{x^2} \left( \frac{1}{2} \right)^{2-1-1}$$

Solving for  $x$ ,

$$x = 0.999958$$

Then,

$$y = x = 0.999958$$

$$z = 2 - 2x = 8.4 \times 10^{-5}$$

Therefore, the equilibrium composition of the mixture at 1000 K and 1 atm is

$$0.999958 \text{ N}_2 + 0.999958 \text{ O}_2 + 8.4 \times 10^{-5} \text{ NO}$$

The mole fraction of NO is then

$$y_{\text{NO}} = \frac{N_{\text{NO}}}{N_{\text{total}}} = \frac{8.4 \times 10^{-5}}{2} = \mathbf{4.2 \times 10^{-5}} \quad (42 \text{ parts per million})$$

$\text{N}_2, \text{O}_2$   
1000 K  
1 atm

**16-23** Oxygen is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

**Assumptions** **1** The equilibrium composition consists of  $O_2$  and  $O$ . **2** The constituents of the mixture are ideal gases.

**Analysis** (a) Obtaining oxygen properties from table A-19, an energy balance gives

$$\underbrace{E_{in} - E_{out}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{system}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$q_{in} = \bar{u}_2 - \bar{u}_1$$

$$= 57,192 - 6203$$

$$= \mathbf{50,989 \text{ kJ/kmol}}$$

$O_2$   
2200 K  
1 atm

(b) The stoichiometric and actual reactions in this case are

Stoichiometric:  $O_2 \Leftrightarrow 2O$  (thus  $\nu_{O_2} = 1$  and  $\nu_O = 2$ )

Actual:  $O_2 \longrightarrow \underbrace{xO_2}_{\text{react.}} + \underbrace{yO}_{\text{products}}$

O balance:  $2 = 2x + y \longrightarrow y = 2 - 2x$

Total number of moles:  $N_{total} = x + y = 2 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{total}} \right)^{\nu_O - \nu_{O_2}}$$

From Table A-28, at 2200 K,  $\ln K_p = -11.827$ . Then,

$$K_p = \exp(-11.827) = 7.305 \times 10^{-6}$$

Substituting,

$$7.305 \times 10^{-6} = \frac{(2-2x)^2}{x} \left( \frac{1}{2-x} \right)^{2-1}$$

Solving for  $x$ ,

$$x = 0.99865$$

Then,

$$y = 2 - 2x = 0.0027$$

Therefore, the equilibrium composition of the mixture at 2200 K and 1 atm is

$$0.99865 O_2 + 0.0027 O$$

Hence, the oxygen ions are negligible and the result is same as that in part (a),

$$q_{in} = \mathbf{50,989 \text{ kJ/kmol}}$$

**16-24** Air is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

**Assumptions** 1 The equilibrium composition consists of  $O_2$  and  $O$ , and  $N_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** (a) Obtaining air properties from table A-17, an energy balance gives

$$\underbrace{E_{in} - E_{out}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{system}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$\begin{aligned} q_{in} &= u_2 - u_1 \\ &= 1872.4 - 212.64 \\ &= \mathbf{1660 \text{ kJ/kg}} \end{aligned}$$

$O_2, 3.76N_2$   
 2200 K  
 1 atm

(b) The stoichiometric and actual reactions in this case are

Stoichiometric:  $O_2 \leftrightarrow 2O$  (thus  $\nu_{O_2} = 1$  and  $\nu_O = 2$ )

Actual:  $O_2 + 3.76N_2 \longrightarrow \underbrace{xO_2}_{\text{react.}} + \underbrace{yO}_{\text{products}} + \underbrace{3.76N_2}_{\text{inert}}$

O balance:  $2 = 2x + y \longrightarrow y = 2 - 2x$

Total number of moles:  $N_{total} = x + y + 3.76 = 5.76 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{total}} \right)^{\nu_O - \nu_{O_2}}$$

From Table A-28, at 2200 K,  $\ln K_p = -11.827$ . Then,

$$K_p = \exp(-11.827) = 7.305 \times 10^{-6}$$

Substituting,

$$7.305 \times 10^{-6} = \frac{(2-2x)^2}{x} \left( \frac{1}{5.76-x} \right)^{2-1}$$

Solving for  $x$ ,

$$x = 0.99706$$

Then,

$$y = 2 - 2x = 0.00588$$

Therefore, the equilibrium composition of the mixture at 2200 K and 1 atm is

$$0.99706 O_2 + 0.00588 O + 3.76 N_2$$

Hence, the atomic oxygen is negligible and the result is same as that in part (a),

$$q_{in} = \mathbf{1660 \text{ kJ/kg}}$$

**16-25** The equilibrium constant of the reaction  $\text{H}_2 + 1/2\text{O}_2 \leftrightarrow \text{H}_2\text{O}$  is listed in Table A-28 at different temperatures. The data are to be verified at two temperatures using Gibbs function data.

**Analysis** (a) The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 25°C,

$$\Delta G^*(T) = 1(-228,590) - 1(0) - 0.5(0) = -228,590 \text{ kJ / kmol}$$

Substituting,

$$\ln K_p = -(-228,590 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = 92.26$$

or

$$K_p = \mathbf{1.12 \times 10^{40}} \quad (\text{Table A - 28: } \ln K_p = 92.21)$$

(b) At 2000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} - \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &\quad - \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad - \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &= 1 \times (-241,820 + 82,593 - 9904 - 2000 \times 264.571) \\ &\quad - 1 \times (0 + 61,400 - 8468 - 2000 \times 188.297) \\ &\quad - 0.5 \times (0 + 67,881 - 8682) - 2000 \times 268.655) \\ &= -135,556 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(-135,556 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})] = 8.152$$

or

$$K_p = \mathbf{3471} \quad (\text{Table A - 28: } \ln K_p = 8.145)$$

**16-26E** The equilibrium constant of the reaction  $\text{H}_2 + 1/2\text{O}_2 \leftrightarrow \text{H}_2\text{O}$  is listed in Table A-28 at different temperatures. The data are to be verified at two temperatures using Gibbs function data.

**Analysis** (a) The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 537 R,

$$\Delta G^*(T) = 1(-98,350) - 1(0) - 0.5(0) = -98,350 \text{ Btu/lbmol}$$

Substituting,

$$\ln K_p = -(-98,350 \text{ Btu/lbmol}) / [(1.986 \text{ Btu/lbmol} \cdot \text{R})(537 \text{ R})] = 92.22$$

or

$$K_p = \mathbf{1.12 \times 10^{40}} \quad (\text{Table A - 28: } \ln K_p = 92.21)$$

(b) At 3240 R,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} - \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{3240} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &\quad - \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{3240} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad - \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{3240} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &= 1 \times (-104,040 + 31,204.5 - 4258 - 3240 \times 61.948) \\ &\quad - 1 \times (0 + 23,484.7 - 3640.3 - 3240 \times 44.125) \\ &\quad - 0.5 \times (0 + 25,972 - 3725.1 - 3240 \times 63.224) \\ &= -63,385 \text{ Btu/lbmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(-63,385 \text{ Btu/lbmol}) / [(1.986 \text{ Btu/lbmol} \cdot \text{R})(3240 \text{ R})] = 9.85$$

or

$$K_p = \mathbf{1.90 \times 10^4} \quad (\text{Table A - 28: } \ln K_p = 9.83)$$

537 R

**16-27** The equilibrium constant of the reaction  $\text{CO} + 1/2\text{O}_2 \leftrightarrow \text{CO}_2$  at 298 K and 2000 K are to be determined, and compared with the values listed in Table A-28.

**Analysis** (a) The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 298 K,

$$\Delta G^*(T) = 1(-394,360) - 1(-137,150) - 0.5(0) = -257,210 \text{ kJ/kmol}$$

where the Gibbs functions are obtained from Table A-26. Substituting,

$$\ln K_p = -\frac{(-257,210 \text{ kJ/kmol})}{(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})} = \mathbf{103.81}$$

From Table A-28:  $\ln K_p = \mathbf{103.76}$

(b) At 2000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} - \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= 1[(-302,128) - (2000)(309.00)] - 1[(-53,826) - (2000)(258.48)] - 0.5[(59,193) - (2000)(268.53)] \\ &= -110,409 \text{ kJ/kmol} \end{aligned}$$

The enthalpies at 2000 K and entropies at 2000 K and 101.3 kPa (1 atm) are obtained from EES. Substituting,

$$\ln K_p = -\frac{(-110,409 \text{ kJ/kmol})}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})} = \mathbf{6.64}$$

From Table A-28:

$$\ln K_p = \mathbf{6.635}$$

**16-28 EES** The effect of varying the percent excess air during the steady-flow combustion of hydrogen is to be studied.

**Analysis** The combustion equation of hydrogen with stoichiometric amount of air is

For the incomplete combustion with 100% excess air, the combustion equation is

The coefficients are to be determined from the mass balances

Hydrogen balance:  $2 = 0.97 \times 2 + a \times 2 \longrightarrow a = 0.03$

Oxygen balance:  $(1 + Ex) \times 0.5 \times 2 = 0.97 + b \times 2$

Nitrogen balance:  $(1 + Ex) \times 0.5 \times 3.76 \times 2 = c \times 2$

Solving the above equations, we find the coefficients ( $Ex = 1$ ,  $a = 0.03$ ,  $b = 0.515$ ,  $c = 3.76$ ) and write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 0.97 + 0.03 + 0.515 + 3.76 = 5.275$$

The assumed equilibrium reaction is

The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2\text{O}}$$

The equilibrium constant is also given by

$$K_p = \left( \frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} \frac{ab^{0.5}}{0.97^1} = \left( \frac{1}{5.275} \right)^{0.5} \frac{(0.03)(0.515)^{0.5}}{0.97} = 0.009664$$

and  $\ln K_p = \ln(0.009664) = -4.647$

The corresponding temperature is obtained solving the above equations using EES to be

$$T_{\text{prod}} = \mathbf{2600 \text{ K}}$$

This is the temperature at which 97 percent of  $\text{H}_2$  will burn into  $\text{H}_2\text{O}$ . The copy of EES solution is given next.

**16-29** The equilibrium constant of the reaction  $\text{CH}_4 + 2\text{O}_2 \leftrightarrow \text{CO}_2 + 2\text{H}_2\text{O}$  at  $25^\circ\text{C}$  is to be determined.

**Analysis** The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

$25^\circ\text{C}$

At  $25^\circ\text{C}$ ,

$$\Delta G^*(T) = 1(-394,360) + 2(-228,590) - 1(-50,790) - 2(0) = -800,750 \text{ kJ / kmol}$$

Substituting,

$$\ln K_p = -(-800,750 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = 323.04$$

or

$$K_p = 1.96 \times 10^{140}$$

**16-30** The equilibrium constant of the reaction  $\text{CO}_2 \leftrightarrow \text{CO} + 1/2\text{O}_2$  is listed in Table A-28 at different temperatures. It is to be verified using Gibbs function data.

**Analysis** (a) The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where  $\Delta G^*(T) = \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T)$

At 298 K,

$$\Delta G^*(T) = 1(-137,150) + 0.5(0) - 1(-394,360) = 257,210 \text{ kJ/kmol}$$

Substituting,

$$\ln K_p = -(257,210 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = -103.81$$

or  $K_p = 8.24 \times 10^{-46}$  (Table A - 28 :  $\ln K_p = -103.76$ )

(b) At 1800 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) \\ &= \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} \\ &= \nu_{\text{CO}} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{CO}} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{CO}_2} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{CO}_2} \\ &= 1 \times (-110,530 + 58,191 - 8669 - 1800 \times 254.797) \\ &\quad + 0.5 \times (0 + 60,371 - 8682 - 1800 \times 264.701) \\ &\quad - 1 \times (-393,520 + 88,806 - 9364 - 1800 \times 302.884) \\ &= 127,240.2 \text{ kJ/kmol} \end{aligned}$$

Substituting,  $\ln K_p = -(127,240.2 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(1800 \text{ K})] = -8.502$

or  $K_p = 2.03 \times 10^{-4}$  (Table A - 28 :  $\ln K_p = -8.497$ )

**16-31** [Also solved by EES on enclosed CD] Carbon monoxide is burned with 100 percent excess air. The temperature at which 97 percent of CO burn to CO<sub>2</sub> is to be determined.

**Assumptions** **1** The equilibrium composition consists of CO<sub>2</sub>, CO, O<sub>2</sub>, and N<sub>2</sub>. **2** The constituents of the mixture are ideal gases.

**Analysis** Assuming N<sub>2</sub> to remain as an inert gas, the stoichiometric and actual reactions can be written as

Stoichiometric:  $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$  (thus  $\nu_{\text{CO}_2} = 1$ ,  $\nu_{\text{CO}} = 1$ , and  $\nu_{\text{O}_2} = \frac{1}{2}$ )

Actual:  $\text{CO} + 1(\text{O}_2 + 3.76 \text{N}_2) \longrightarrow \underbrace{0.97 \text{CO}_2}_{\text{product}} + \underbrace{0.03 \text{CO} + 0.515 \text{O}_2}_{\text{reactants}} + \underbrace{3.76 \text{N}_2}_{\text{inert}}$

The equilibrium constant  $K_p$  can be determined from

$$\begin{aligned} K_p &= \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})} \\ &= \frac{0.97}{0.03 \times 0.515^{0.5}} \left( \frac{1}{0.97 + 0.03 + 0.515 + 3.76} \right)^{1-1.5} \\ &= 103.48 \end{aligned}$$

From Table A-28, the temperature corresponding to this  $K_p$  value is  $T = 2276 \text{ K}$

**16-32 EES** Problem 16-31 is reconsidered. The effect of varying the percent excess air during the steady-flow process from 0 to 200 percent on the temperature at which 97 percent of CO burn into CO<sub>2</sub> is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

"To solve this problem, we need to give EES a guess value for T<sub>prod</sub> other than the default value of 1. Set the guess value of T<sub>prod</sub> to 1000 K by selecting Variable Information in the Options menu. Then press F2 or click the Calculator icon."

"Input Data from the diagram window:"

**16-33E** Carbon monoxide is burned with 100 percent excess air. The temperature at which 97 percent of CO burn to CO<sub>2</sub> is to be determined.

**Assumptions** 1 The equilibrium composition consists of CO<sub>2</sub>, CO, O<sub>2</sub>, and N<sub>2</sub>. 2 The constituents of the mixture are ideal gases.

**Analysis** Assuming N<sub>2</sub> to remain as an inert gas, the stoichiometric and actual reactions can be written as

Stoichiometric:  $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$  (thus  $\nu_{\text{CO}_2} = 1$ ,  $\nu_{\text{CO}} = 1$ , and  $\nu_{\text{O}_2} = \frac{1}{2}$ )

Actual:  $\text{CO} + 1(\text{O}_2 + 3.76 \text{N}_2) \longrightarrow \underbrace{0.97 \text{CO}_2}_{\text{product}} + \underbrace{0.03 \text{CO} + 0.515 \text{O}_2}_{\text{reactants}} + \underbrace{3.76 \text{N}_2}_{\text{inert}}$

The equilibrium constant  $K_p$  can be determined from

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

$$= \frac{0.97}{0.03 \times 0.515^{0.5}} \left( \frac{1}{0.97 + 0.03 + 0.515 + 3.76} \right)^{1-1.5}$$

$$= 103.48$$

From Table A-28, the temperature corresponding to this  $K_p$  value is  $T = 2276 \text{ K} = 4097 \text{ R}$

**16-34** Hydrogen is burned with 150 percent theoretical air. The temperature at which 98 percent of H<sub>2</sub> will burn to H<sub>2</sub>O is to be determined.

**Assumptions** 1 The equilibrium composition consists of H<sub>2</sub>O, H<sub>2</sub>, O<sub>2</sub>, and N<sub>2</sub>. 2 The constituents of the mixture are ideal gases.

**Analysis** Assuming N<sub>2</sub> to remain as an inert gas, the stoichiometric and actual reactions can be written as

Stoichiometric:  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{H}_2\text{O}$  (thus  $\nu_{\text{H}_2\text{O}} = 1$ ,  $\nu_{\text{H}_2} = 1$ , and  $\nu_{\text{O}_2} = \frac{1}{2}$ )

Actual:  $\text{H}_2 + 0.75(\text{O}_2 + 3.76 \text{N}_2) \longrightarrow \underbrace{0.98 \text{H}_2\text{O}}_{\text{product}} + \underbrace{0.02 \text{H}_2 + 0.26 \text{O}_2}_{\text{reactants}} + \underbrace{2.82 \text{N}_2}_{\text{inert}}$

The equilibrium constant  $K_p$  can be determined from

$$K_p = \frac{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}}{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2\text{O}} - \nu_{\text{H}_2} - \nu_{\text{O}_2})}$$

$$= \frac{0.98}{0.02 \times 0.26^{0.5}} \left( \frac{1}{0.98 + 0.02 + 0.26 + 2.82} \right)^{1-1.5}$$

$$= 194.11$$

From Table A-28, the temperature corresponding to this  $K_p$  value is  $T = 2472 \text{ K}$ .

**16-35** Air is heated to a high temperature. The equilibrium composition at that temperature is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $N_2$ ,  $O_2$ , and  $NO$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\frac{1}{2} N_2 + \frac{1}{2} O_2 \rightleftharpoons NO$  (thus  $\nu_{NO} = 1$ ,  $\nu_{N_2} = \frac{1}{2}$ , and  $\nu_{O_2} = \frac{1}{2}$ )

Actual:  $3.76 N_2 + O_2 \longrightarrow \underbrace{x NO}_{\text{prod.}} + \underbrace{y N_2 + z O_2}_{\text{reactants}}$

N balance:  $7.52 = x + 2y$  or  $y = 3.76 - 0.5x$

O balance:  $2 = x + 2z$  or  $z = 1 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z = x + 4.76 - x = 4.76$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{NO}^{\nu_{NO}}}{N_{N_2}^{\nu_{N_2}} N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{NO} - \nu_{N_2} - \nu_{O_2})}$$

From Table A-28,  $\ln K_p = -3.931$  at 2000 K. Thus  $K_p = 0.01962$ . Substituting,

$$0.01962 = \frac{x}{(3.76 - 0.5x)^{0.5} (1 - 0.5x)^{0.5}} \left( \frac{2}{4.76} \right)^{1-1}$$

Solving for  $x$ ,

$$x = 0.0376$$

Then,

$$y = 3.76 - 0.5x = 3.7412$$

$$z = 1 - 0.5x = 0.9812$$

Therefore, the equilibrium composition of the mixture at 2000 K and 2 atm is

The equilibrium constant for the reactions  $O_2 \rightleftharpoons 2O$  ( $\ln K_p = -14.622$ ) and  $N_2 \rightleftharpoons 2N$  ( $\ln K_p = -41.645$ ) are much smaller than that of the specified reaction ( $\ln K_p = -3.931$ ). Therefore, it is realistic to assume that no monatomic oxygen or nitrogen will be present in the equilibrium mixture. Also the equilibrium composition is in this case is independent of pressure since  $\Delta \nu = 1 - 0.5 - 0.5 = 0$ .

AIR  
2000 K  
2 atm

**16-36** Hydrogen is heated to a high temperature at a constant pressure. The percentage of  $H_2$  that will dissociate into H is to be determined.

**Assumptions** **1** The equilibrium composition consists of  $H_2$  and H. **2** The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions can be written as

Stoichiometric:  $H_2 \Leftrightarrow 2H$  (thus  $\nu_{H_2} = 1$  and  $\nu_H = 2$ )

Actual:  $H_2 \longrightarrow \underbrace{xH_2}_{\text{react.}} + \underbrace{yH}_{\text{prod.}}$

H balance:  $2 = 2x + y$  or  $y = 2 - 2x$

Total number of moles:  $N_{\text{total}} = x + y = x + 2 - 2x = 2 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_H^{\nu_H}}{N_{H_2}^{\nu_{H_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_H - \nu_{H_2}}$$

From Table A-28,  $\ln K_p = -2.534$  at 3200 K. Thus  $K_p = 0.07934$ . Substituting,

$$0.07934 = \frac{(2 - 2x)^2}{x} \left( \frac{8}{2 - x} \right)^{2-1}$$

Solving for  $x$ ,  $x = 0.95$

Thus the percentage of  $H_2$  which dissociates to H at 3200 K and 8 atm is

$$1 - 0.95 = 0.05 \text{ or } 5.0\%$$

**16-37E** A mixture of CO, O<sub>2</sub>, and N<sub>2</sub> is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

**Assumptions** 1 The equilibrium composition consists of CO<sub>2</sub>, CO, O<sub>2</sub>, and N<sub>2</sub>. 2 The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{CO} + \frac{1}{2} \text{O}_2 \rightleftharpoons \text{CO}_2$  (thus  $\nu_{\text{CO}_2} = 1$ ,  $\nu_{\text{CO}} = 1$ , and  $\nu_{\text{O}_2} = \frac{1}{2}$ )

Actual:  $2 \text{CO} + 2 \text{O}_2 + 6 \text{N}_2 \longrightarrow \underbrace{x \text{CO}_2}_{\text{products}} + \underbrace{y \text{CO} + z \text{O}_2}_{\text{reactants}} + \underbrace{6 \text{N}_2}_{\text{inert}}$

|                  |
|------------------|
| 2 CO             |
| 2 O <sub>2</sub> |
| 6 N <sub>2</sub> |
| 4320 R           |
| 3 atm            |

C balance:  $2 = x + y \longrightarrow y = 2 - x$

O balance:  $6 = 2x + y + 2z \longrightarrow z = 2 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z + 6 = 10 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

From Table A-28,  $\ln K_p = 3.860$  at  $T = 4320$  R = 2400 K. Thus  $K_p = 47.465$ . Substituting,

$$47.465 = \frac{x}{(2-x)(2-0.5x)^{0.5}} \left( \frac{3}{10-0.5x} \right)^{1-1.5}$$

Solving for  $x$ ,

$$x = 1.930$$

Then,

$$y = 2 - x = 0.070$$

$$z = 2 - 0.5x = 1.035$$

Therefore, the equilibrium composition of the mixture at 2400 K and 3 atm is

**16-38** A mixture of  $N_2$ ,  $O_2$ , and Ar is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $N_2$ ,  $O_2$ , Ar, and NO. 2 The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\frac{1}{2} N_2 + \frac{1}{2} O_2 \rightleftharpoons NO$  (thus  $\nu_{NO} = 1$ ,  $\nu_{N_2} = \frac{1}{2}$ , and  $\nu_{O_2} = \frac{1}{2}$ )

Actual:  $3 N_2 + O_2 + 0.1 Ar \longrightarrow \underbrace{x NO}_{\text{prod.}} + \underbrace{y N_2 + z O_2}_{\text{reactants}} + \underbrace{0.1 Ar}_{\text{inert}}$

|         |
|---------|
| 3 $N_2$ |
| 1 $O_2$ |
| 0.1 Ar  |
| 2400 K  |
| 10 atm  |

N balance:  $6 = x + 2y \longrightarrow y = 3 - 0.5x$

O balance:  $2 = x + 2z \longrightarrow z = 1 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z + 0.1 = 4.1$

The equilibrium constant relation becomes,

$$K_p = \frac{N_{NO}^{\nu_{NO}}}{N_{N_2}^{\nu_{N_2}} N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{NO} - \nu_{N_2} - \nu_{O_2})} = \frac{x}{y^{0.5} z^{0.5}} \left( \frac{P}{N_{\text{total}}} \right)^{1-0.5-0.5}$$

From Table A-28,  $\ln K_p = -3.019$  at 2400 K. Thus  $K_p = 0.04885$ . Substituting,

$$0.04885 = \frac{x}{(3 - 0.5x)^{0.5} (1 - 0.5x)^{0.5}} \times 1$$

Solving for  $x$ ,

$$x = 0.0823$$

Then,

$$y = 3 - 0.5x = 2.9589$$

$$z = 1 - 0.5x = 0.9589$$

Therefore, the equilibrium composition of the mixture at 2400 K and 10 atm is

**16-39** The mole fraction of sodium that ionizes according to the reaction  $\text{Na} \rightleftharpoons \text{Na}^+ + \text{e}^-$  at 2000 K and 0.8 atm is to be determined.

**Assumptions** All components behave as ideal gases.

**Analysis** The stoichiometric and actual reactions can be written as

Stoichiometric:  $\text{Na} \rightleftharpoons \text{Na}^+ + \text{e}^-$  (thus  $\nu_{\text{Na}} = 1$ ,  $\nu_{\text{Na}^+} = 1$  and  $\nu_{\text{e}^-} = 1$ )

Actual:  $\text{Na} \longrightarrow \underbrace{x\text{Na}}_{\text{react.}} + \underbrace{y\text{Na}^+ + y\text{e}^-}_{\text{products}}$

Na balance:  $1 = x + y$  or  $y = 1 - x$

Total number of moles:  $N_{\text{total}} = x + 2y = 2 - x$

The equilibrium constant relation becomes,

$$K_p = \frac{N_{\text{Na}}^{\nu_{\text{Na}}} N_{\text{e}^-}^{\nu_{\text{e}^-}}}{N_{\text{Na}^+}^{\nu_{\text{Na}^+}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{Na}^+} + \nu_{\text{e}^-} - \nu_{\text{Na}})} = \frac{y^2}{x} \left( \frac{P}{N_{\text{total}}} \right)^{1+1-1}$$

Substituting,

$$0.668 = \frac{(1-x)^2}{x} \left( \frac{0.8}{2-x} \right)$$

Solving for  $x$ ,

$$x = 0.325$$

Thus the fraction of Na which dissociates into  $\text{Na}^+$  and  $\text{e}^-$  is

$$1 - 0.325 = 0.675 \quad \text{or} \quad \mathbf{67.5\%}$$

**16-40** Liquid propane enters a combustion chamber. The equilibrium composition of product gases and the rate of heat transfer from the combustion chamber are to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}$ ,  $\text{N}_2$ , and  $\text{O}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis (a)** Considering 1 kmol of  $\text{C}_3\text{H}_8$ , the stoichiometric combustion equation can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient and is determined from the  $\text{O}_2$  balance,

$$2.5a_{\text{th}} = 3 + 2 + 1.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Then the actual combustion equation with 150% excess air and some CO in the products can be written as

After combustion, there will be no  $\text{C}_3\text{H}_8$  present in the combustion chamber, and  $\text{H}_2\text{O}$  will act like an inert gas. The equilibrium equation among  $\text{CO}_2$ ,  $\text{CO}$ , and  $\text{O}_2$  can be expressed as

and

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

where

$$N_{\text{total}} = x + (3-x) + (9-0.5x) + 4 + 47 = 63 - 0.5x$$

From Table A-28,  $\ln K_p = -17.871$  at 1200 K. Thus  $K_p = 1.73 \times 10^{-8}$ . Substituting,

$$1.73 \times 10^{-8} = \frac{(3-x)(9-0.5x)^{0.5}}{x} \left( \frac{2}{63-0.5x} \right)^{1.5-1}$$

Solving for  $x$ ,

$$x = 2.9999999 \cong 3.0$$

Therefore, the amount CO in the product gases is negligible, and it can be disregarded with no loss in accuracy. Then the combustion equation and the equilibrium composition can be expressed as

and

(b) The heat transfer for this combustion process is determined from the steady-flow energy balance

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \quad \text{on the combustion chamber with } W = 0,$$

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables, (The  $\bar{h}_f^\circ$  of liquid propane is obtained by adding the  $h_{fg}$  at 25°C to  $\bar{h}_f^\circ$  of gaseous propane).

| Substance                         | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{285\text{ K}}$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{1200\text{ K}}$<br>kJ/kmol |
|-----------------------------------|------------------------------|-------------------------------------|-------------------------------------|--------------------------------------|
| C <sub>3</sub> H <sub>8</sub> (ℓ) | -118,910                     | ---                                 | ---                                 | ---                                  |
| O <sub>2</sub>                    | 0                            | 8696.5                              | 8682                                | 38,447                               |
| N <sub>2</sub>                    | 0                            | 8286.5                              | 8669                                | 36,777                               |
| H <sub>2</sub> O (g)              | -241,820                     | ---                                 | 9904                                | 44,380                               |
| CO <sub>2</sub>                   | -393,520                     | ---                                 | 9364                                | 53,848                               |

Substituting,

$$\begin{aligned}
 -Q_{\text{out}} &= 3(-393,520 + 53,848 - 9364) + 4(-241,820 + 44,380 - 9904) \\
 &\quad + 7.5(0 + 38,447 - 8682) + 47(0 + 36,777 - 8669) \\
 &\quad - 1(-118,910 + h_{298} - h_{298}) - 12.5(0 + 8296.5 - 8682) \\
 &\quad - 47(0 + 8186.5 - 8669) \\
 &= -185,764 \text{ kJ / kmol of C}_3\text{H}_8
 \end{aligned}$$

or

$$Q_{\text{out}} = 185,764 \text{ kJ / kmol of C}_3\text{H}_8$$

The mass flow rate of C<sub>3</sub>H<sub>8</sub> can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{1.2 \text{ kg / min}}{44 \text{ kg / kmol}} = 0.02727 \text{ kmol / min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{out}} = \dot{N} \times Q_{\text{out}} = (0.02727 \text{ kmol/min})(185,746 \text{ kJ/kmol}) = \mathbf{5066 \text{ kJ/min}}$$

The equilibrium constant for the reaction  $\frac{1}{2} \text{N}_2 + \frac{1}{2} \text{O}_2 \rightleftharpoons \text{NO}$  is  $\ln K_p = -7.569$ , which is very small. This indicates that the amount of NO formed during this process will be very small, and can be disregarded.

**16-41 EES** Problem 16-40 is reconsidered. It is to be investigated if it is realistic to disregard the presence of NO in the product gases.

**Analysis** The problem is solved using EES, and the solution is given below.

"To solve this problem, the Gibbs function of the product gases is minimized. Click on the Min/Max icon."

For this problem at 1200 K the moles of CO are 0.000 and moles of NO are 0.000, thus we can disregard both the CO and NO. However, try some product temperatures above 1286 K and observe the sign change on the Q\_out and the amount of CO and NO present as the product temperature increases."

"The reaction of C<sub>3</sub>H<sub>8</sub>(l) with excess air can be written:

The coefficients A<sub>th</sub> and EX are the theoretical oxygen and the percent excess air on a decimal basis. Coefficients a, b, c, d, e, and f are found by minimizing the Gibbs Free Energy at a total pressure of the product gases P<sub>Prod</sub> and the product temperature T<sub>Prod</sub>.

The equilibrium solution can be found by applying the Law of Mass Action or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, click on the Min/Max icon. There are six compounds present in the products subject to four specie balances, so there are two degrees of freedom. Minimize the Gibbs function of the product gases with respect to two molar quantities such as coefficients b and f. The equilibrium mole numbers a, b, c, d, e, and f will be determined and displayed in the Solution window."

$$y_{\text{N}_2} = 0.7642$$

$$y_{\text{NO}} = 7.857\text{E-}08$$

$$y_{\text{O}_2} = 0.122$$

**16-42** Oxygen is heated during a steady-flow process. The rate of heat supply needed during this process is to be determined for two cases.

**Assumptions 1** The equilibrium composition consists of  $O_2$  and  $O$ . **2** All components behave as ideal gases.

**Analysis (a)** Assuming some  $O_2$  dissociates into  $O$ , the dissociation equation can be written as

The equilibrium equation among  $O_2$  and  $O$  can be expressed as

Assuming ideal gas behavior for all components, the equilibrium constant relation can be expressed as

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}}$$

where  $N_{\text{total}} = x + 2(1-x) = 2-x$

From Table A-28,  $\ln K_p = -4.357$  at 3000 K. Thus  $K_p = 0.01282$ . Substituting,

$$0.01282 = \frac{(2-2x)^2}{x} \left( \frac{1}{2-x} \right)^{2-1}$$

Solving for  $x$  gives  $x = 0.943$

Then the dissociation equation becomes

The heat transfer for this combustion process is determined from the steady-flow energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  on the combustion chamber with  $W = 0$ ,

$$\dot{Q}_{\text{in}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the  $O_2$  and  $O$  to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{3000 \text{ K}}$<br>kJ/kmol |
|-----------|------------------------------|--------------------------------------|---------------------------------------|
| O         | 249,190                      | 6852                                 | 63,425                                |
| $O_2$     | 0                            | 8682                                 | 106,780                               |

Substituting,

$$\dot{Q}_{\text{in}} = 0.943(0 + 106,780 - 8682) + 0.114(249,190 + 63,425 - 6852) - 0 = 127,363 \text{ kJ / kmol } O_2$$

The mass flow rate of  $O_2$  can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.5 \text{ kg/min}}{32 \text{ kg/kmol}} = 0.01563 \text{ kmol/min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{in}} = \dot{N} \times \dot{Q}_{\text{in}} = (0.01563 \text{ kmol/min})(127,363 \text{ kJ/kmol}) = \mathbf{1990 \text{ kJ/min}}$$

(b) If no  $O_2$  dissociates into  $O$ , then the process involves no chemical reactions and the heat transfer can be determined from the steady-flow energy balance for nonreacting systems to be

$$\dot{Q}_{\text{in}} = \dot{m}(h_2 - h_1) = \dot{N}(\bar{h}_2 - \bar{h}_1) = (0.01563 \text{ kmol/min})(106,780 - 8682) \text{ kJ/kmol} = \mathbf{1533 \text{ kJ/min}}$$

**16-43** The equilibrium constant,  $K_p$  is to be estimated at 2500 K for the reaction  $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$ .

**Analysis** (a) The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 2500 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} + \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= 1[(-271,641) - (2500)(322.60)] + 1[(70,452) - (2500)(196.10)] \\ &\quad - 1[(-35,510) - (2500)(266.65)] - 1[(-142,891) - (2500)(276.18)] \\ &= 37,525 \text{ kJ/kmol} \end{aligned}$$

The enthalpies at 2500 K and entropies at 2500 K and 101.3 kPa (1 atm) are obtained from EES. Substituting,

$$\ln K_p = -\frac{37,525 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2500 \text{ K})} = -1.8054 \longrightarrow K_p = \mathbf{0.1644}$$

The equilibrium constant may be estimated using the integrated van't Hoff equation:

$$\begin{aligned} \ln \left( \frac{K_{p,\text{est}}}{K_{p1}} \right) &= \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_R} - \frac{1}{T} \right) \\ \ln \left( \frac{K_{p,\text{est}}}{0.2209} \right) &= \frac{-26,176 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left( \frac{1}{2000 \text{ K}} - \frac{1}{2500 \text{ K}} \right) \longrightarrow K_{p,\text{est}} = \mathbf{0.1612} \end{aligned}$$

**16-44** A constant volume tank contains a mixture of H<sub>2</sub> and O<sub>2</sub>. The contents are ignited. The final temperature and pressure in the tank are to be determined.

**Analysis** The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

$$\text{Hydrogen balance:} \quad 2 = 2a + 2b$$

$$\text{Oxygen balance:} \quad 2 = b + 2c$$

The assumed equilibrium reaction is

The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}})$$

and the Gibbs functions are given by

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2\text{O}}$$

The equilibrium constant is also given by

$$K_p = \frac{a^1 c^{0.5}}{b^1} \left( \frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{ac^{0.5}}{b} \left( \frac{P_2/101.3}{a+b+c} \right)^{0.5}$$

An energy balance on the tank under adiabatic conditions gives

$$U_R = U_P$$

where

$$\begin{aligned} U_R &= 1(\bar{h}_{\text{H}_2@25^\circ\text{C}} - R_u T_{\text{reac}}) + 1(\bar{h}_{\text{O}_2@25^\circ\text{C}} - R_u T_{\text{reac}}) \\ &= 0 - (8.314 \text{ kJ/kmol}\cdot\text{K})(298.15 \text{ K}) + 0 - (8.314 \text{ kJ/kmol}\cdot\text{K})(298.15 \text{ K}) = -4958 \text{ kJ/kmol} \end{aligned}$$

$$U_P = a(\bar{h}_{\text{H}_2@T_{\text{prod}}} - R_u T_{\text{prod}}) + b(\bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} - R_u T_{\text{prod}}) + c(\bar{h}_{\text{O}_2@T_{\text{prod}}} - R_u T_{\text{prod}})$$

The relation for the final pressure is

$$P_2 = \frac{N_{\text{tot}}}{N_1} \frac{T_{\text{prod}}}{T_{\text{reac}}} P_1 = \left( \frac{a+b+c}{2} \right) \left( \frac{T_{\text{prod}}}{298.15 \text{ K}} \right) (101.3 \text{ kPa})$$

Solving all the equations simultaneously using EES, we obtain the final temperature and pressure in the tank to be

$$\begin{aligned} T_{\text{prod}} &= \mathbf{3857 \text{ K}} \\ P_2 &= \mathbf{1043 \text{ kPa}} \end{aligned}$$

## Simultaneous Reactions

**16-45C** It can be expressed as “ $(dG)_{T,P} = 0$  for each reaction.” Or as “the  $K_p$  relation for each reaction must be satisfied.”

**16-46C** The number of  $K_p$  relations needed to determine the equilibrium composition of a reacting mixture is equal to the difference between the number of species present in the equilibrium mixture and the number of elements.

**16-47** Two chemical reactions are occurring in a mixture. The equilibrium composition at a specified temperature is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{OH}$ ,  $\text{O}_2$ , and  $\text{H}_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The reaction equation during this process can be expressed as

Mass balances for hydrogen and oxygen yield

$$\text{H balance:} \quad 2 = 2x + 2y + w \quad (1)$$

$$\text{O balance:} \quad 1 = x + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_p$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3400 K are determined from Table A-28 to be

$$\ln K_{P1} = -1.891 \longrightarrow K_{P1} = 0.15092$$

$$\ln K_{P2} = -1.576 \longrightarrow K_{P2} = 0.20680$$

The  $K_p$  relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})} \quad \text{and} \quad K_{P2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

$$\text{where} \quad N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.15092 = \frac{(y)(z)^{1/2}}{x} \left( \frac{1}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.20680 = \frac{(w)(y)^{1/2}}{x} \left( \frac{1}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 0.574 \quad y = 0.308 \quad z = 0.095 \quad w = 0.236$$

Therefore, the equilibrium composition becomes

**16-48** Two chemical reactions are occurring in a mixture. The equilibrium composition at a specified temperature is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{O}$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The reaction equation during this process can be expressed as

Mass balances for carbon and oxygen yield

$$\text{C balance:} \quad 2 = x + y \quad (1)$$

$$\text{O balance:} \quad 6 = 2x + y + 2z + w \quad (2)$$

$\text{CO}_2, \text{CO}, \text{O}_2, \text{O}$   
3200 K  
2 atm

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_P$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3200 K are determined from Table A-28 to be

$$\ln K_{P1} = -0.429 \longrightarrow K_{P1} = 0.65116$$

$$\ln K_{P2} = -3.072 \longrightarrow K_{P2} = 0.04633$$

The  $K_P$  relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

$$K_{P2} = \frac{N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{O}} - \nu_{\text{O}_2}}$$

where

$$N_{\text{total}} = N_{\text{CO}_2} + N_{\text{O}_2} + N_{\text{CO}} + N_{\text{O}} = x + y + z + w$$

Substituting,

$$0.65116 = \frac{(y)(z)^{1/2}}{x} \left( \frac{2}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.04633 = \frac{w^2}{z} \left( \frac{2}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 1.127 \quad y = 0.873 \quad z = 1.273 \quad w = 0.326$$

Thus the equilibrium composition is

**16-49** Two chemical reactions are occurring at high-temperature air. The equilibrium composition at a specified temperature is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $O_2$ ,  $N_2$ ,  $O$ , and  $NO$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The reaction equation during this process can be expressed as

Mass balances for nitrogen and oxygen yield

$$\text{N balance:} \quad 7.52 = 2x + y \quad (1)$$

$$\text{O balance:} \quad 2 = y + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_p$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3000 K are determined from Table A-28 to be

$$\ln K_{p1} = -2.114 \longrightarrow K_{p1} = 0.12075$$

$$\ln K_{p2} = -4.357 \longrightarrow K_{p2} = 0.01282$$

The  $K_p$  relations for these two simultaneous reactions are

$$K_{p1} = \frac{N_{NO}^{v_{NO}}}{N_{N_2}^{v_{N_2}} N_{O_2}^{v_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(v_{NO} - v_{N_2} - v_{O_2})}$$

$$K_{p2} = \frac{N_O^{v_O}}{N_{O_2}^{v_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{v_O - v_{O_2}}$$

$$\text{where} \quad N_{\text{total}} = N_{N_2} + N_{NO} + N_{O_2} + N_O = x + y + z + w$$

Substituting,

$$0.12075 = \frac{y}{x^{0.5} z^{0.5}} \left( \frac{2}{x + y + z + w} \right)^{1-0.5-0.5} \quad (3)$$

$$0.01282 = \frac{w^2}{z} \left( \frac{2}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 3.656 \quad y = 0.2086 \quad z = 0.8162 \quad w = 0.1591$$

Thus the equilibrium composition is

The equilibrium constant of the reaction  $N_2 \rightleftharpoons 2N$  at 3000 K is  $\ln K_p = -22.359$ , which is much smaller than the  $K_p$  values of the reactions considered. Therefore, it is reasonable to assume that no  $N$  will be present in the equilibrium mixture.

**16-50E** [Also solved by EES on enclosed CD] Two chemical reactions are occurring in air. The equilibrium composition at a specified temperature is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $O_2$ ,  $N_2$ ,  $O$ , and  $NO$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The reaction equation during this process can be expressed as

Mass balances for nitrogen and oxygen yield

$$\text{N balance:} \quad 7.52 = 2x + y \quad (1)$$

$$\text{O balance:} \quad 2 = y + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_p$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at  $T = 5400 \text{ R} = 3000 \text{ K}$  are determined from Table A-28 to be

$$\ln K_{P1} = -2.114 \longrightarrow K_{P1} = 0.12075$$

$$\ln K_{P2} = -4.357 \longrightarrow K_{P2} = 0.01282$$

The  $K_p$  relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{NO}^{v_{NO}}}{N_{N_2}^{v_{N_2}} N_{O_2}^{v_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(v_{NO} - v_{N_2} - v_{O_2})}$$

$$K_{P2} = \frac{N_O^{v_O}}{N_{O_2}^{v_{O_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{v_O - v_{O_2}}$$

$$\text{where} \quad N_{\text{total}} = N_{N_2} + N_{NO} + N_{O_2} + N_O = x + y + z + w$$

Substituting,

$$0.12075 = \frac{y}{x^{0.5} z^{0.5}} \left( \frac{1}{x + y + z + w} \right)^{1-0.5-0.5} \quad (3)$$

$$0.01282 = \frac{w^2}{z} \left( \frac{1}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 3.658 \quad y = 0.2048 \quad z = 0.7868 \quad w = 0.2216$$

Thus the equilibrium composition is

The equilibrium constant of the reaction  $N_2 \rightleftharpoons 2N$  at 5400 R is  $\ln K_p = -22.359$ , which is much smaller than the  $K_p$  values of the reactions considered. Therefore, it is reasonable to assume that no N will be present in the equilibrium mixture.

**14-51E EES** Problem 16-50E is reconsidered. Using EES (or other) software, the equilibrium solution is to be obtained by minimizing the Gibbs function by using the optimization capabilities built into EES. This solution technique is to be compared with that used in the previous problem.

**Analysis** The problem is solved using EES, and the solution is given below.

"This example illustrates how EES can be used to solve multi-reaction chemical equilibria problems by directly minimizing the Gibbs function.

Two of the four coefficients, a, b, c, and d, are found by minimizing the Gibbs function at a total pressure of 1 atm and a temperature of 5400 R. The other two are found from mass balances.

The equilibrium solution can be found by applying the Law of Mass Action to two simultaneous equilibrium reactions or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, select MinMax from the Calculate menu. There are four compounds present in the products subject to two elemental balances, so there are two degrees of freedom.

Minimize

**Discussion** The equilibrium composition in the above table are based on the reaction in which the reactants are 0.21 kmol  $O_2$  and 0.79 kmol  $N_2$ . If you multiply the equilibrium composition mole numbers above with 4.76, you will obtain equilibrium composition for the reaction in which the reactants are 1 kmol  $O_2$  and 3.76 kmol  $N_2$ . This is the case in problem 16-43E.

**16-52** Water vapor is heated during a steady-flow process. The rate of heat supply for a specified exit temperature is to be determined for two cases.

**Assumptions** **1** The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{OH}$ ,  $\text{O}_2$ , and  $\text{H}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** (a) Assuming some  $\text{H}_2\text{O}$  dissociates into  $\text{H}_2$ ,  $\text{O}_2$ , and  $\text{O}$ , the dissociation equation can be written as

Mass balances for hydrogen and oxygen yield

$$\text{H balance:} \quad 2 = 2x + 2y + w \quad (1)$$

$$\text{O balance:} \quad 1 = x + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_P$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3000 K are determined from Table A-28 to be

$$\ln K_{P1} = -3.086 \longrightarrow K_{P1} = 0.04568$$

$$\ln K_{P2} = -2.937 \longrightarrow K_{P2} = 0.05302$$

The  $K_P$  relations for these three simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

$$K_{P2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

where

$$N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.04568 = \frac{(y)(z)^{1/2}}{x} \left( \frac{1}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.05302 = \frac{(w)(y)^{1/2}}{x} \left( \frac{1}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 0.784 \quad y = 0.162 \quad z = 0.054 \quad w = 0.108$$

Thus the balanced equation for the dissociation reaction is

The heat transfer for this dissociation process is determined from the steady-flow energy balance

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \quad \text{with } W = 0,$$

$$\dot{Q}_{\text{in}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the  $\text{O}_2$  and  $\text{O}$  to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance            | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298 \text{ K}}$<br>kJ/kmol | $\bar{h}_{3000 \text{ K}}$<br>kJ/kmol |
|----------------------|------------------------------|--------------------------------------|---------------------------------------|
| $\text{H}_2\text{O}$ | -241,820                     | 9904                                 | 136,264                               |
| $\text{H}_2$         | 0                            | 8468                                 | 97,211                                |
| $\text{O}_2$         | 0                            | 8682                                 | 106,780                               |
| $\text{OH}$          | 39,460                       | 9188                                 | 98,763                                |

Substituting,

$$\begin{aligned} \dot{Q}_{\text{in}} &= 0.784(-241,820 + 136,264 - 9904) \\ &\quad + 0.162(0 + 97,211 - 8468) \\ &\quad + 0.054(0 + 106,780 - 8682) \\ &\quad + 0.108(39,460 + 98,763 - 9188) - (-241,820) \\ &= 184,909 \text{ kJ / kmol H}_2\text{O} \end{aligned}$$

The mass flow rate of  $\text{H}_2\text{O}$  can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.2 \text{ kg / min}}{18 \text{ kg / kmol}} = 0.01111 \text{ kmol / min}$$

Thus,

$$\dot{Q}_{\text{in}} = \dot{N} \times Q_{\text{in}} = (0.01111 \text{ kmol/min})(184,909 \text{ kJ/kmol}) = \mathbf{2055 \text{ kJ/min}}$$

(b) If no dissociates takes place, then the process involves no chemical reactions and the heat transfer can be determined from the steady-flow energy balance for nonreacting systems to be

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}(h_2 - h_1) = \dot{N}(\bar{h}_2 - \bar{h}_1) \\ &= (0.01111 \text{ kmol / min})(136,264 - 9904) \text{ kJ / kmol} \\ &= \mathbf{1404 \text{ kJ / min}} \end{aligned}$$

**16-53 EES** Problem 16-52 is reconsidered. The effect of the final temperature on the rate of heat supplied for the two cases is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

"This example illustrates how EES can be used to solve multi-reaction chemical equilibria problems by directly minimizing the Gibbs function.

Two of the four coefficients,  $x$ ,  $y$ ,  $z$ , and  $w$  are found by minimizing the Gibbs function at a total pressure of 1 atm and a temperature of 3000 K. The other two are found from mass balances.

The equilibrium solution can be found by applying the Law of Mass Action (Eq. 15-15) to two simultaneous equilibrium reactions or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, click on the Min/Max icon. There are four compounds present in the products subject to two elemental balances, so there are two degrees of freedom. Minimize Gibbs with respect to two molar quantities such as coefficient  $z$  and  $w$ . The equilibrium mole numbers of each specie will be determined and displayed in the Solution window.

Minimizing the Gibbs function to find the equilibrium composition requires good initial guesses."

**16-54 EES** Ethyl alcohol  $\text{C}_2\text{H}_5\text{OH}$  (gas) is burned in a steady-flow adiabatic combustion chamber with 40 percent excess air. The adiabatic flame temperature of the products is to be determined and the adiabatic flame temperature as a function of the percent excess air is to be plotted.

**Analysis** The complete combustion reaction in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. The oxygen balance gives

$$1 + (1 + Ex)a_{\text{th}} \times 2 = 2 \times 2 + 3 \times 1 + (Ex)(a_{\text{th}}) \times 2$$

The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

Carbon balance:  $2 = a + b$

Hydrogen balance:  $6 = 2d \longrightarrow d = 3$

Oxygen balance:  $1 + (1 + Ex)a_{\text{th}} \times 2 = a \times 2 + b + d + e \times 2 + g$

Nitrogen balance:  $(1 + Ex)a_{\text{th}} \times 3.76 \times 2 = f \times 2 + g$

Solving the above equations, we find the coefficients to be

$$Ex = 0.4, a_{\text{th}} = 3, a = 1.995, b = 0.004712, d = 3, e = 1.17, f = 15.76, g = 0.06428$$

Then, we write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 1.995 + 0.004712 + 3 + 1.17 + 15.76 = 21.99$$

The first assumed equilibrium reaction is

The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_{p1} = \exp\left(\frac{-\Delta G_1^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right)$$

Where  $\Delta G_1^*(T_{\text{prod}}) = \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_{\text{prod}})$

and the Gibbs functions are defined as

$$\bar{g}_{\text{CO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}_2}$$

The equilibrium constant is also given by

$$K_{p1} = \frac{be^{0.5}}{a} \left( \frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{(0.004712)(1.17)^{0.5}}{1.995} \left( \frac{1}{21.99} \right)^{0.5} = 0.0005447$$

The second assumed equilibrium reaction is

Also, for this reaction, we have

$$\bar{g}_{\text{NO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{NO}}$$

$$\bar{g}_{\text{N}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{N}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{O}_2}$$

$$\Delta G_2^*(T_{\text{prod}}) = \nu_{\text{NO}}\bar{g}_{\text{NO}}^*(T_{\text{prod}}) - \nu_{\text{N}_2}\bar{g}_{\text{N}_2}^*(T_{\text{prod}}) - \nu_{\text{O}_2}\bar{g}_{\text{O}_2}^*(T_{\text{prod}})$$

$$K_{p2} = \exp\left(\frac{-\Delta G_2^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right)$$

$$K_{p2} = \left(\frac{P}{N_{\text{tot}}}\right)^{1-0.5-0.5} \frac{g}{e^{0.5} f^{0.5}} = \left(\frac{1}{21.99}\right)^0 \frac{0.06428}{(1.17)^{0.5} (15.76)^{0.5}} = 0.01497$$

A steady flow energy balance gives

$$H_R = H_P$$

where

$$\begin{aligned} H_R &= \bar{h}_{f,\text{fuel}@25^\circ\text{C}}^\circ + 4.2\bar{h}_{\text{O}_2@25^\circ\text{C}} + 15.79\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= (-235,310 \text{ kJ/kmol}) + 4.2(0) + 15.79(0) = -235,310 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} H_P &= 1.995\bar{h}_{\text{CO}_2@T_{\text{prod}}} + 0.004712\bar{h}_{\text{CO}@T_{\text{prod}}} + 3\bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} + 1.17\bar{h}_{\text{O}_2@T_{\text{prod}}} \\ &\quad + 15.76\bar{h}_{\text{N}_2@T_{\text{prod}}} + 0.06428\bar{h}_{\text{NO}@T_{\text{prod}}} \end{aligned}$$

Solving the energy balance equation using EES, we obtain the adiabatic flame temperature

$$T_{\text{prod}} = \mathbf{1901 \text{ K}}$$

The copy of entire EES solution including parametric studies is given next:

"The reactant temperature is:"

T\_reac= 25+273 "[K]"

"For adiabatic combustion of 1 kmol of fuel: "

Q\_out = 0 "[kJ]"

PercentEx = 40 "Percent excess air"

Ex = PercentEx/100 "EX = % Excess air/100"

P\_prod = 101.3 "[kPa]"

R\_u = 8.314 "[kJ/kmol-K]"

"The complete combustion reaction equation for excess air is:"

"C2H5OH(gas)+ (1+Ex)\*A\_th (O2 + 3.76N2)=2 CO2 + 3 H2O + Ex\*A\_th O2 + f N2 "

"Oxygen Balance for complete combustion:"

1 + (1+Ex)\*A\_th\*2=2\*2+3\*1 + Ex\*A\_th\*2

"The reaction equation for excess air and products in equilibrium is:"

"C2H5OH(gas)+ (1+Ex)\*A\_th (O2 + 3.76N2)=a CO2 + b CO+ d H2O + e O2 + f N2 + g NO"

"Carbon Balance:"

$$2 = a + b$$

"Hydrogen Balance:"

$$6 = 2d$$

"Oxygen Balance:"

$$1 + (1+Ex)A_{th} = a + b + d + e + g$$

"Nitrogen Balance:"

$$(1+Ex)A_{th} \cdot 3.76 = f + g$$

$N_{tot} = a + b + d + e + f + g$  "Total kilomoles of products at equilibrium"

"The first assumed equilibrium reaction is  $CO_2 = CO + 0.5O_2$ "

"The following equations provide the specific Gibbs function ( $g = h - Ts$ ) for each component in the product gases as a function of its temperature,  $T_{prod}$ , at 1 atm pressure, 101.3 kPa"

$$g_{CO_2} = \text{Enthalpy}(CO_2, T=T_{prod}) - T_{prod} \cdot \text{Entropy}(CO_2, T=T_{prod}, P=101.3)$$

$$g_{CO} = \text{Enthalpy}(CO, T=T_{prod}) - T_{prod} \cdot \text{Entropy}(CO, T=T_{prod}, P=101.3)$$

$$g_{O_2} = \text{Enthalpy}(O_2, T=T_{prod}) - T_{prod} \cdot \text{Entropy}(O_2, T=T_{prod}, P=101.3)$$

"The standard-state Gibbs function is"

$$\Delta G_1 = 1 \cdot g_{CO} + 0.5 \cdot g_{O_2} - 1 \cdot g_{CO_2}$$

"The equilibrium constant is given by Eq. 15-14."

$$K_{P_1} = \exp(-\Delta G_1 / (R_u \cdot T_{prod}))$$

$$P = P_{prod} / 101.3 \text{ "atm"}$$

"The equilibrium constant is also given by Eq. 15-15."

$$K_{P_1} = (P/N_{tot})^{(1+0.5-1)} \cdot (b^1 \cdot e^{0.5}) / (a^1)$$

**Variations of  $K_p$  with Temperature**

**16-55C** It enables us to determine the enthalpy of reaction  $\bar{h}_R$  from a knowledge of equilibrium constant  $K_p$ .

**16-56C** At 2000 K since combustion processes are exothermic, and exothermic reactions are more complete at lower temperatures.

**16-57** The  $\bar{h}_R$  at a specified temperature is to be determined using the enthalpy and  $K_P$  data.

**Assumptions** Both the reactants and products are ideal gases.

**Analysis** (a) The complete combustion equation of CO can be expressed as

The  $\bar{h}_R$  of the combustion process of CO at 2200 K is the amount of energy released as one kmol of CO is burned in a steady-flow combustion chamber at a temperature of 2200 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO, O<sub>2</sub> and CO<sub>2</sub> to be ideal gases, we have  $h = h(T)$ . From the tables,

|                 | $\bar{h}_f^\circ$ | $\bar{h}_{298 \text{ K}}$ | $\bar{h}_{2200 \text{ K}}$ |
|-----------------|-------------------|---------------------------|----------------------------|
| Substance       | kJ/kmol           | kJ/kmol                   | kJ/kmol                    |
| CO <sub>2</sub> | -393,520          | 9364                      | 112,939                    |
| CO              | -110,530          | 8669                      | 72,688                     |
| O <sub>2</sub>  | 0                 | 8682                      | 75,484                     |

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-393,520 + 112,939 - 9364) \\ &\quad - 1(-110,530 + 72,688 - 8669) \\ &\quad - 0.5(0 + 75,484 - 8682) \\ &= \mathbf{-276,835 \text{ kJ / kmol}} \end{aligned}$$

(b) The  $\bar{h}_R$  value at 2200 K can be estimated by using  $K_P$  values at 2000 K and 2400 K (the closest two temperatures to 2200 K for which  $K_P$  data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \\ 3.860 - 6.635 &\cong \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left( \frac{1}{2000 \text{ K}} - \frac{1}{2400 \text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{-276,856 \text{ kJ/kmol}} \end{aligned}$$

**16-58E** The  $\bar{h}_R$  at a specified temperature is to be determined using the enthalpy and  $K_P$  data.

**Assumptions** Both the reactants and products are ideal gases.

**Analysis** (a) The complete combustion equation of CO can be expressed as

The  $\bar{h}_R$  of the combustion process of CO at 3960 R is the amount of energy released as one kmol of  $\text{H}_2$  is burned in a steady-flow combustion chamber at a temperature of 3960 R, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO,  $\text{O}_2$  and  $\text{CO}_2$  to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance     | $\bar{h}_f^\circ$<br>Btu/lbmol | $\bar{h}_{537\text{ R}}$<br>Btu/lbmol | $\bar{h}_{3960\text{ R}}$<br>Btu/lbmol |
|---------------|--------------------------------|---------------------------------------|----------------------------------------|
| $\text{CO}_2$ | -169,300                       | 4027.5                                | 48,647                                 |
| CO            | -47,540                        | 3725.1                                | 31,256.5                               |
| $\text{O}_2$  | 0                              | 3725.1                                | 32,440.5                               |

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-169,300 + 48,647 - 4027.5) \\ &\quad - 1(-47,540 + 31,256.5 - 3725.1) \\ &\quad - 0.5(0 + 32,440.5 - 3725.1) \\ &= \mathbf{-119,030 \text{ Btu / lbmol}} \end{aligned}$$

(b) The  $\bar{h}_R$  value at 3960 R can be estimated by using  $K_P$  values at 3600 R and 4320 R (the closest two temperatures to 3960 R for which  $K_P$  data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \\ 3.860 - 6.635 &\cong \frac{\bar{h}_R}{1.986 \text{ Btu/lbmol} \cdot \text{R}} \left( \frac{1}{3600 \text{ R}} - \frac{1}{4320 \text{ R}} \right) \\ \bar{h}_R &\cong \mathbf{-119,041 \text{ Btu/lbmol}} \end{aligned}$$

**16-59** The  $K_P$  value of the combustion process  $\text{H}_2 + 1/2\text{O}_2 \rightleftharpoons \text{H}_2\text{O}$  is to be determined at a specified temperature using  $\bar{h}_R$  data and  $K_P$  value.

**Assumptions** Both the reactants and products are ideal gases.

**Analysis** The  $\bar{h}_R$  and  $K_P$  data are related to each other by

$$\ln \frac{K_{P2}}{K_{P1}} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

The  $\bar{h}_R$  of the specified reaction at 2400 K is the amount of energy released as one kmol of  $\text{H}_2$  is burned in a steady-flow combustion chamber at a temperature of 2400 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the  $\text{H}_2\text{O}$ ,  $\text{H}_2$  and  $\text{O}_2$  to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance            | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{2400\text{ K}}$<br>kJ/kmol |
|----------------------|------------------------------|-------------------------------------|--------------------------------------|
| $\text{H}_2\text{O}$ | -241,820                     | 9904                                | 103,508                              |
| $\text{H}_2$         | 0                            | 8468                                | 75,383                               |
| $\text{O}_2$         | 0                            | 8682                                | 83,174                               |

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-241,820 + 103,508 - 9904) \\ &\quad - 1(0 + 75,383 - 8468) \\ &\quad - 0.5(0 + 83,174 - 8682) \\ &= -252,377 \text{ kJ / kmol} \end{aligned}$$

The  $K_P$  value at 2600 K can be estimated from the equation above by using this  $\bar{h}_R$  value and the  $K_P$  value at 2200 K which is  $\ln K_{P1} = 6.768$ ,

$$\ln K_{P2} - 6.768 \cong \frac{-252,377 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left( \frac{1}{2200 \text{ K}} - \frac{1}{2600 \text{ K}} \right)$$

$$\ln K_{P2} = 4.645 \quad (\text{Table A - 28: } \ln K_{P2} = 4.648)$$

or

$$K_{P2} = \mathbf{104.1}$$

**16-60** The  $\bar{h}_R$  value for the dissociation process  $\text{CO}_2 \Leftrightarrow \text{CO} + 1/2\text{O}_2$  at a specified temperature is to be determined using enthalpy and  $K_p$  data.

**Assumptions** Both the reactants and products are ideal gases.

**Analysis** (a) The dissociation equation of  $\text{CO}_2$  can be expressed as

The  $\bar{h}_R$  of the dissociation process of  $\text{CO}_2$  at 2200 K is the amount of energy absorbed or released as one kmol of  $\text{CO}_2$  dissociates in a steady-flow combustion chamber at a temperature of 2200 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the  $\text{CO}$ ,  $\text{O}_2$  and  $\text{CO}_2$  to be ideal gases, we have  $h = h(T)$ . From the tables,

|--------------|------------------------------|-------------------------------------|--------------------------------------|
| O            | 249,190                      | 6852                                | 65,520                               |
| $\text{O}_2$ | 0                            | 8682                                | 110,784                              |

Substituting,

$$\begin{aligned}\bar{h}_R &= 2(249,190 + 65,520 - 6852) - 1(0 + 110,784 - 8682) \\ &= \mathbf{513,614\text{ kJ/kmol}}\end{aligned}$$

(b) The  $\bar{h}_R$  value at 3100 K can be estimated by using  $K_P$  values at 3000 K and 3200 K (the closest two temperatures to 3100 K for which  $K_P$  data are available) from Table A-28,

$$\begin{aligned}\ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \\ -3.072 - (-4.357) &\cong \frac{\bar{h}_R}{8.314\text{ kJ/kmol} \cdot \text{K}} \left( \frac{1}{3000\text{ K}} - \frac{1}{3200\text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{512,808\text{ kJ/kmol}}\end{aligned}$$

**16-62** The enthalpy of reaction for the equilibrium reaction  $\text{CH}_4 + 2\text{O}_2 = \text{CO}_2 + 2\text{H}_2\text{O}$  at 2500 K is to be estimated using enthalpy data and equilibrium constant,  $K_p$  data.

**Analysis** The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At  $T_1 = 2500 - 10 = 2490 \text{ K}$ :

$$\begin{aligned} \Delta G_1^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_1) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_1) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T_1) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_1) \\ &= 1(-1.075 \times 10^6) + 2(-830,577) - 1(-717,973) - 2(-611,582) \\ &= -794,929 \text{ kJ/kmol} \end{aligned}$$

At  $T_2 = 2500 + 10 = 2510 \text{ K}$ :

$$\begin{aligned} \Delta G_2^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_2) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_2) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T_2) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_2) \\ &= 1(-1.081 \times 10^6) + 2(-836,100) - 1(-724,516) - 2(-617,124) \\ &= -794,801 \text{ kJ/kmol} \end{aligned}$$

The Gibbs functions are obtained from enthalpy and entropy properties using EES. Substituting,

$$K_{p1} = \exp\left(-\frac{-794,929 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2490 \text{ K})}\right) = 4.747 \times 10^{16}$$

$$K_{p2} = \exp\left(-\frac{-794,801 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2510 \text{ K})}\right) = 3.475 \times 10^{16}$$

The enthalpy of reaction is determined by using the integrated van't Hoff equation:

$$\begin{aligned} \ln\left(\frac{K_{p2}}{K_{p1}}\right) &= \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2}\right) \\ \ln\left(\frac{3.475 \times 10^{16}}{4.747 \times 10^{16}}\right) &= \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2490 \text{ K}} - \frac{1}{2510 \text{ K}}\right) \longrightarrow \bar{h}_R = -810,845 \text{ kJ/kmol} \end{aligned}$$

The enthalpy of reaction can also be determined from an energy balance to be

$$\bar{h}_R = H_P - H_R$$

where

$$\begin{aligned} H_R &= 1\bar{h}_{\text{CH}_4 @ 2500 \text{ K}} + 2\bar{h}_{\text{O}_2 @ 2500 \text{ K}} = 96,668 + 2(78,377) = 253,422 \text{ kJ/kmol} \\ H_P &= 1\bar{h}_{\text{CO}_2 @ 2500 \text{ K}} + 2\bar{h}_{\text{H}_2\text{O} @ 2500 \text{ K}} = (-271,641) + 2(-142,891) = -557,423 \text{ kJ/kmol} \end{aligned}$$

The enthalpies are obtained from EES. Substituting,

$$\bar{h}_R = H_P - H_R = (-557,423) - (253,422) = -810,845 \text{ kJ/kmol}$$

which is identical to the value obtained using  $K_p$  data.

## Phase Equilibrium

**16-63C** No. Because the specific gibbs function of each phase will not be affected by this process; i.e., we will still have  $g_f = g_g$ .

**16-64C** Yes. Because the number of independent variables for a two-phase (PH=2), two-component (C=2) mixture is, from the phase rule,

$$IV = C - PH + 2 = 2 - 2 + 2 = 2$$

Therefore, two properties can be changed independently for this mixture. In other words, we can hold the temperature constant and vary the pressure and still be in the two-phase region. Notice that if we had a single component (C=1) two phase system, we would have IV=1, which means that fixing one independent property automatically fixes all the other properties.

**11-65C** Using solubility data of a solid in a specified liquid, the mass fraction  $w$  of the solid  $A$  in the liquid at the interface at a specified temperature can be determined from

$$mf_A = \frac{m_{\text{solid}}}{m_{\text{solid}} + m_{\text{liquid}}}$$

where  $m_{\text{solid}}$  is the maximum amount of solid dissolved in the liquid of mass  $m_{\text{liquid}}$  at the specified temperature.

**11-66C** The molar concentration  $C_i$  of the gas species  $i$  in the solid at the interface  $C_{i, \text{solid side}}(0)$  is proportional to the *partial pressure* of the species  $i$  in the gas  $P_{i, \text{gas side}}(0)$  on the gas side of the interface, and is determined from

$$C_{i, \text{solid side}}(0) = S \times P_{i, \text{gas side}}(0) \quad (\text{kmol/m}^3)$$

where  $S$  is the *solubility* of the gas in that solid at the specified temperature.

**11-67C** Using Henry's constant data for a gas dissolved in a liquid, the mole fraction of the gas dissolved in the liquid at the interface at a specified temperature can be determined from Henry's law expressed as

$$y_{i, \text{liquid side}}(0) = \frac{P_{i, \text{gas side}}(0)}{H}$$

where  $H$  is *Henry's constant* and  $P_{i, \text{gas side}}(0)$  is the partial pressure of the gas  $i$  at the gas side of the interface. This relation is applicable for dilute solutions (gases that are weakly soluble in liquids).

**16-68** It is to be shown that a mixture of saturated liquid water and saturated water vapor at 100°C satisfies the criterion for phase equilibrium.

**Analysis** Using the definition of Gibbs function and enthalpy and entropy data from Table A-4,

$$g_f = h_f - Ts_f = (419.17 \text{ kJ/kg}) - (373.15 \text{ K})(1.3072 \text{ kJ/kg} \cdot \text{K}) = -68.61 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (2675.6 \text{ kJ/kg}) - (373.15 \text{ K})(7.3542 \text{ kJ/kg} \cdot \text{K}) = -68.62 \text{ kJ/kg}$$

which are practically same. Therefore, the criterion for phase equilibrium is satisfied.

**16-69** It is to be shown that a mixture of saturated liquid water and saturated water vapor at 300 kPa satisfies the criterion for phase equilibrium.

**Analysis** The saturation temperature at 300 kPa is 406.7 K. Using the definition of Gibbs function and enthalpy and entropy data from Table A-5,

$$g_f = h_f - Ts_f = (561.43 \text{ kJ/kg}) - (406.7 \text{ K})(1.6717 \text{ kJ/kg} \cdot \text{K}) = -118.5 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (2724.9 \text{ kJ/kg}) - (406.7 \text{ K})(6.9917 \text{ kJ/kg} \cdot \text{K}) = -118.6 \text{ kJ/kg}$$

which are practically same. Therefore, the criterion for phase equilibrium is satisfied.

**16-70** It is to be shown that a saturated liquid-vapor mixture of refrigerant-134a at -10°C satisfies the criterion for phase equilibrium.

**Analysis** Using the definition of Gibbs function and enthalpy and entropy data from Table A-11,

$$g_f = h_f - Ts_f = (38.55 \text{ kJ/kg}) - (263.15 \text{ K})(0.15504 \text{ kJ/kg} \cdot \text{K}) = -2.249 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (244.51 \text{ kJ/kg}) - (263.15 \text{ K})(0.93766 \text{ kJ/kg} \cdot \text{K}) = -2.235 \text{ kJ/kg}$$

which are sufficiently close. Therefore, the criterion for phase equilibrium is satisfied.

**16-71** The number of independent properties needed to fix the state of a mixture of oxygen and nitrogen in the gas phase is to be determined.

**Analysis** In this case the number of components is  $C = 2$  and the number of phases is  $PH = 1$ . Then the number of independent variables is determined from the phase rule to be

$$IV = C - PH + 2 = 2 - 1 + 2 = 3$$

Therefore, three independent properties need to be specified to fix the state. They can be temperature, the pressure, and the mole fraction of one of the gases.

**16-72** The values of the Gibbs function for saturated refrigerant-134a at 0°C as a saturated liquid, saturated vapor, and a mixture of liquid and vapor are to be calculated.

**Analysis** Obtaining properties from Table A-11, the Gibbs function for the liquid phase is,

$$g_f = h_f - Ts_f = 51.86 \text{ kJ/kg} - (273.15 \text{ K})(0.20439 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.97 \text{ kJ/kg}}$$

For the vapor phase,

$$g_g = h_g - Ts_g = 250.45 \text{ kJ/kg} - (273.15 \text{ K})(0.93139 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.96 \text{ kJ/kg}}$$

For the saturated mixture with a quality of 30%,

$$h = h_f + xh_{fg} = 51.86 \text{ kJ/kg} + (0.30)(198.60 \text{ kJ/kg}) = 111.44 \text{ kJ/kg}$$

$$s = s_f + xs_{fg} = 0.20439 \text{ kJ/kg} \cdot \text{K} + (0.30)(0.72701 \text{ kJ/kg} \cdot \text{K}) = 0.42249 \text{ kJ/kg} \cdot \text{K}$$

$$g = h - Ts = 111.44 \text{ kJ/kg} - (273.15 \text{ K})(0.42249 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.96 \text{ kJ/kg}}$$

The results agree and demonstrate that phase equilibrium exists.

R-134a  
0°C

**16-73** The values of the Gibbs function for saturated refrigerant-134a at -10°C are to be calculated.

**Analysis** Obtaining properties from Table A-11, the Gibbs function for the liquid phase is,

$$g_f = h_f - Ts_f = 38.55 \text{ kJ/kg} - (263.15 \text{ K})(0.15504 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-2.25 \text{ kJ/kg}}$$

For the vapor phase,

$$g_g = h_g - Ts_g = 244.51 \text{ kJ/kg} - (263.15 \text{ K})(0.93766 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-2.24 \text{ kJ/kg}}$$

The results agree and demonstrate that phase equilibrium exists.

R-134a  
-10°C  
 $x = 0.4$

**16-74** Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the temperature is to be determined for a specified composition of the nitrogen and the mass fraction of the oxygen at this temperature is to be determined.

**Analysis** From the equilibrium diagram (Fig. 16-21) we read  $T = \mathbf{88 \text{ K}}$ .

For the liquid phase, from the same figure,

$$y_{f,\text{O}_2} = 0.90 \quad \text{and} \quad y_{f,\text{N}_2} = 0.10$$

Then,

$$\text{mf}_{f,\text{O}_2} = \frac{m_{f,\text{O}_2}}{m_{f,\text{total}}} = \frac{y_{f,\text{O}_2} M_{\text{O}_2}}{y_{f,\text{O}_2} M_{\text{O}_2} + y_{f,\text{N}_2} M_{\text{N}_2}} = \frac{(0.90)(32)}{(0.90)(32) + (0.10)(28)} = \mathbf{0.911}$$

**16-75** A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The pressure of ammonia is to be determined for two compositions of the liquid phase.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Analysis** According to Raoult's law, when the mole fraction of the ammonia liquid is 20%,

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.20(615.3 \text{ kPa}) = \mathbf{123.1 \text{ kPa}}$$

When the mole fraction of the ammonia liquid is 80%,

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.80(615.3 \text{ kPa}) = \mathbf{492.2 \text{ kPa}}$$

**16-76** A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The composition of the liquid phase is given. The composition of the vapor phase is to be determined.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Properties** At 25°C,  $P_{\text{sat},\text{H}_2\text{O}} = 3.170 \text{ kPa}$  and  $P_{\text{sat},\text{NH}_3} = 1003.5 \text{ kPa}$ .

**Analysis** The vapor pressures are

$$P_{\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat},\text{H}_2\text{O}}(T) = 0.50(3.170 \text{ kPa}) = 1.585 \text{ kPa}$$

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.50(1003.5 \text{ kPa}) = 501.74 \text{ kPa}$$

Thus the total pressure of the mixture is

$$P_{\text{total}} = P_{\text{H}_2\text{O}} + P_{\text{NH}_3} = (1.585 + 501.74) \text{ kPa} = 503.33 \text{ kPa}$$

Then the mole fractions in the vapor phase become

$$y_{g,\text{H}_2\text{O}} = \frac{P_{\text{H}_2\text{O}}}{P_{\text{total}}} = \frac{1.585 \text{ kPa}}{503.33 \text{ kPa}} = \mathbf{0.0031} \text{ or } 0.31\%$$

$$y_{g,\text{NH}_3} = \frac{P_{\text{NH}_3}}{P_{\text{total}}} = \frac{501.74 \text{ kPa}}{503.33 \text{ kPa}} = \mathbf{0.9969} \text{ or } 99.69\%$$

**16-77** A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The composition of the vapor phase is given. The composition of the liquid phase is to be determined.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Properties** At 50°C,  $P_{\text{sat,H}_2\text{O}} = 12.352 \text{ kPa}$  and  $P_{\text{sat,NH}_3} = 2033.5 \text{ kPa}$ .

**Analysis** We have  $y_{g,\text{H}_2\text{O}} = 1\%$  and  $y_{g,\text{NH}_3} = 99\%$ . For an ideal two-phase mixture we have

$$y_{g,\text{H}_2\text{O}}P_m = y_{f,\text{H}_2\text{O}}P_{\text{sat,H}_2\text{O}}(T)$$

$$y_{g,\text{NH}_3}P_m = y_{f,\text{NH}_3}P_{\text{sat,NH}_3}(T)$$

$$y_{f,\text{H}_2\text{O}} + y_{f,\text{NH}_3} = 1$$

Solving for  $y_{f,\text{H}_2\text{O}}$ ,

$$y_{f,\text{H}_2\text{O}} = \frac{y_{g,\text{H}_2\text{O}}P_{\text{sat,NH}_3}}{y_{g,\text{NH}_3}P_{\text{sat,H}_2\text{O}}}(1 - y_{f,\text{H}_2\text{O}}) = \frac{(0.01)(2033.5 \text{ kPa})}{(0.99)(12.352 \text{ kPa})}(1 - y_{f,\text{H}_2\text{O}})$$

It yields

$$y_{f,\text{H}_2\text{O}} = \mathbf{0.624} \quad \text{and} \quad y_{f,\text{NH}_3} = \mathbf{0.376}$$

**16-78** Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture, the composition of each phase at a specified temperature and pressure is to be determined.

**Analysis** From the equilibrium diagram (Fig. 16-21) we read

Liquid: 30%  $\text{N}_2$  and 70%  $\text{O}_2$

Vapor: 66%  $\text{N}_2$  and 34%  $\text{O}_2$

**16-79** Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the temperature is to be determined for a specified composition of the vapor phase.

**Analysis** From the equilibrium diagram (Fig. 16-21) we read  $T = \mathbf{82 \text{ K}}$ .

**16-80** Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the temperature is to be determined for a specified composition of the liquid phase.

**Analysis** From the equilibrium diagram (Fig. 16-21) we read  $T = \mathbf{84 \text{ K}}$ .

**16-81** A rubber wall separates  $O_2$  and  $N_2$  gases. The molar concentrations of  $O_2$  and  $N_2$  in the wall are to be determined.

**Assumptions** The  $O_2$  and  $N_2$  gases are in phase equilibrium with the rubber wall.

**Properties** The molar mass of oxygen and nitrogen are 32.0 and 28.0 kg/kmol, respectively (Table A-1). The solubility of oxygen and nitrogen in rubber at 298 K are 0.00312 and 0.00156 kmol/m<sup>3</sup>·bar, respectively (Table 16-3).

**Analysis** Noting that 500 kPa = 5 bar, the molar densities of oxygen and nitrogen in the rubber wall are determined to be

$$\begin{aligned} C_{O_2, \text{ solid side}}(0) &= S \times P_{O_2, \text{ gas side}} \\ &= (0.00312 \text{ kmol/m}^3 \cdot \text{bar})(5 \text{ bar}) \\ &= \mathbf{0.0156 \text{ kmol/m}^3} \end{aligned}$$

$$\begin{aligned} C_{N_2, \text{ solid side}}(0) &= S \times P_{N_2, \text{ gas side}} \\ &= (0.00156 \text{ kmol/m}^3 \cdot \text{bar})(5 \text{ bar}) \\ &= \mathbf{0.0078 \text{ kmol/m}^3} \end{aligned}$$

That is, there will be 0.0156 kmol of  $O_2$  and 0.0078 kmol of  $N_2$  gas in each m<sup>3</sup> volume of the rubber wall.

**16-82** An ammonia-water absorption refrigeration unit is considered. The operating pressures in the generator and absorber, and the mole fractions of the ammonia in the strong liquid mixture being pumped from the absorber and the weak liquid solution being drained from the generator are to be determined.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Properties** At  $0^\circ\text{C}$ ,  $P_{\text{sat,H}_2\text{O}} = 0.6112 \text{ kPa}$  and at  $46^\circ\text{C}$ ,  $P_{\text{sat,H}_2\text{O}} = 10.10 \text{ kPa}$  (Table A-4). The saturation pressures of ammonia at the same temperatures are given to be  $430.6 \text{ kPa}$  and  $1830.2 \text{ kPa}$ , respectively.

**Analysis** According to Raoult's law, the partial pressures of ammonia and water are given by

$$P_{\text{g,NH}_3} = y_{f,\text{NH}_3} P_{\text{sat,NH}_3}$$

$$P_{\text{g,H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

Using Dalton's partial pressure model for ideal gas mixtures, the mole fraction of the ammonia in the vapor mixture is

$$y_{g,\text{NH}_3} = \frac{y_{f,\text{NH}_3} P_{\text{sat,NH}_3}}{y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}}$$

$$0.96 = \frac{430.6 y_{f,\text{NH}_3}}{430.6 y_{f,\text{NH}_3} + 0.6112(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.03294}$$

Then,

$$P = y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

$$= (0.03294)(430.6) + (1 - 0.03294)(0.6112) = \mathbf{14.78 \text{ kPa}}$$

Performing the similar calculations for the regenerator,

$$0.96 = \frac{1830.2 y_{f,\text{NH}_3}}{1830.2 y_{f,\text{NH}_3} + 10.10(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.1170}$$

$$P = (0.1170)(1830.2) + (1 - 0.1170)(10.10) = \mathbf{223.1 \text{ kPa}}$$

**16-83** An ammonia-water absorption refrigeration unit is considered. The operating pressures in the generator and absorber, and the mole fractions of the ammonia in the strong liquid mixture being pumped from the absorber and the weak liquid solution being drained from the generator are to be determined.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Properties** At 6°C,  $P_{\text{sat,H}_2\text{O}} = 0.9353 \text{ kPa}$  and at 40°C,  $P_{\text{sat,H}_2\text{O}} = 7.3851 \text{ kPa}$  (Table A-4 or EES). The saturation pressures of ammonia at the same temperatures are given to be 534.8 kPa and 1556.7 kPa, respectively.

**Analysis** According to Raoult's law, the partial pressures of ammonia and water are given by

$$P_{\text{g,NH}_3} = y_{f,\text{NH}_3} P_{\text{sat,NH}_3}$$

$$P_{\text{g,H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

Using Dalton's partial pressure model for ideal gas mixtures, the mole fraction of the ammonia in the vapor mixture is

$$y_{\text{g,NH}_3} = \frac{y_{f,\text{NH}_3} P_{\text{sat,NH}_3}}{y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}}$$

$$0.96 = \frac{534.8 y_{f,\text{NH}_3}}{534.8 y_{f,\text{NH}_3} + 0.9353(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.04028}$$

Then,

$$P = y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

$$= (0.04028)(534.8) + (1 - 0.04028)(0.9353) = \mathbf{22.44 \text{ kPa}}$$

Performing the similar calculations for the regenerator,

$$0.96 = \frac{1556.7 y_{f,\text{NH}_3}}{1556.7 y_{f,\text{NH}_3} + 7.3851(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.1022}$$

$$P = (0.1022)(1556.7) + (1 - 0.1022)(7.3851) = \mathbf{165.7 \text{ kPa}}$$

**16-84** A liquid mixture of water and R-134a is considered. The mole fraction of the water and R-134a vapor are to be determined.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Properties** At 20°C,  $P_{\text{sat,H}_2\text{O}} = 2.3392 \text{ kPa}$  and  $P_{\text{sat,R}} = 572.07 \text{ kPa}$  (Tables A-4, A-11). The molar masses of water and R-134a are 18.015 and 102.03 kg/kmol, respectively (Table A-1).

**Analysis** The mole fraction of the water in the liquid mixture is

$$y_{f,\text{H}_2\text{O}} = \frac{N_{f,\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{\text{mf}_{f,\text{H}_2\text{O}} / M_{\text{H}_2\text{O}}}{(\text{mf}_{f,\text{H}_2\text{O}} / M_{\text{H}_2\text{O}}) + (\text{mf}_{f,\text{R}} / M_{\text{R}})}$$

$$= \frac{0.9 / 18.015}{(0.9 / 18.015) + (0.1 / 102.03)} = 0.9808$$

|                                         |
|-----------------------------------------|
| <p>H<sub>2</sub>O + R-134a<br/>20°C</p> |
|-----------------------------------------|

According to Raoult's law, the partial pressures of R-134a and water in the vapor mixture are

$$P_{g,\text{R}} = y_{f,\text{R}} P_{\text{sat,R}} = (1 - 0.9808)(572.07 \text{ kPa}) = 10.98 \text{ kPa}$$

$$P_{g,\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (0.9808)(2.3392 \text{ kPa}) = 2.294 \text{ kPa}$$

The total pressure of the vapor mixture is then

$$P_{\text{total}} = P_{g,\text{R}} + P_{g,\text{H}_2\text{O}} = 10.98 + 2.294 = 13.274 \text{ kPa}$$

Based on Dalton's partial pressure model for ideal gases, the mole fractions in the vapor phase are

$$y_{g,\text{H}_2\text{O}} = \frac{P_{g,\text{H}_2\text{O}}}{P_{\text{total}}} = \frac{2.294 \text{ kPa}}{13.274 \text{ kPa}} = \mathbf{0.1728}$$

$$y_{g,\text{R}} = \frac{P_{g,\text{R}}}{P_{\text{total}}} = \frac{10.98 \text{ kPa}}{13.274 \text{ kPa}} = \mathbf{0.8272}$$

**16-85E** A mixture of water and R-134a is considered. The mole fractions of the R-134a in the liquid and vapor phases are to be determined.

**Assumptions** The mixture is ideal and thus Raoult's law is applicable.

**Properties** At 77°F,  $P_{\text{sat,H}_2\text{O}} = 0.4597$  psia and  $P_{\text{sat,R}} = 96.56$  psia (Tables A-4E, A-11E or EES).

**Analysis** According to Raoult's law, the partial pressures of R-134a and water in the vapor phase are given by

$$P_{g,R} = y_{f,R} P_{\text{sat,R}} = \frac{N_{f,R}}{N_{f,R} + N_{f,\text{H}_2\text{O}}} (96.56 \text{ psia})$$

$$P_{g,\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = \frac{N_{f,\text{H}_2\text{O}}}{N_{f,\text{H}_2\text{O}} + N_{f,R}} (0.4597 \text{ psia})$$

H<sub>2</sub>O + R-134a  
14.7 psia, 77°F

The sum of these two partial pressures must equal the total pressure of the vapor mixture. In terms of

$x = \frac{N_{f,\text{H}_2\text{O}}}{N_{f,R}}$ , this sum is

$$\frac{96.56}{x+1} + \frac{0.4597x}{x+1} = 14.7$$

Solving this expression for  $x$  gives

$$x = 5.748 \text{ kmol H}_2\text{O/kmol R-134a}$$

In the vapor phase, the partial pressure of the R-134a vapor is

$$P_{g,R} = \frac{96.56}{x+1} = \frac{96.56}{5.748+1} = 14.31 \text{ psia}$$

The mole fraction of R-134a in the vapor phase is then

$$y_{g,R} = \frac{P_{g,R}}{P} = \frac{14.31 \text{ psia}}{14.7 \text{ psia}} = \mathbf{0.9735}$$

According to Raoult's law,

$$y_{f,R} = \frac{P_{g,R}}{P_{\text{sat,R}}} = \frac{14.31 \text{ psia}}{96.56 \text{ psia}} = \mathbf{0.1482}$$

**16-86** A glass of water is left in a room. The mole fraction of the water vapor in the air and the mole fraction of air in the water are to be determined when the water and the air are in thermal and phase equilibrium.

**Assumptions** **1** Both the air and water vapor are ideal gases. **2** Air is saturated since the humidity is 100 percent. **3** Air is weakly soluble in water and thus Henry's law is applicable.

**Properties** The saturation pressure of water at 27°C is 3.568 kPa (Table A-4). Henry's constant for air dissolved in water at 27°C (300 K) is given in Table 16-2 to be  $H = 74,000$  bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

**Analysis** (a) Noting that air is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{\text{sat @ 27°C}} = 3.600 \text{ kPa} \quad (\text{Table A-4})$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air is determined to be

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.600 \text{ kPa}}{97 \text{ kPa}} = \mathbf{0.0371}$$

(b) Noting that the total pressure is 97 kPa, the partial pressure of dry air is

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 97 - 3.600 = 93.4 \text{ kPa} = 0.934 \text{ bar}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gas side}}}{H} = \frac{0.934 \text{ bar}}{74,000 \text{ bar}} = \mathbf{1.26 \times 10^{-5}}$$

**Discussion** The amount of air dissolved in water is very small, as expected.

**16-87** A carbonated drink in a bottle is considered. Assuming the gas space above the liquid consists of a saturated mixture of CO<sub>2</sub> and water vapor and treating the drink as a water, determine the mole fraction of the water vapor in the CO<sub>2</sub> gas and the mass of dissolved CO<sub>2</sub> in a 300 ml drink are to be determined when the water and the CO<sub>2</sub> gas are in thermal and phase equilibrium.

**Assumptions** **1** The liquid drink can be treated as water. **2** Both the CO<sub>2</sub> and the water vapor are ideal gases. **3** The CO<sub>2</sub> gas and water vapor in the bottle form a saturated mixture. **4** The CO<sub>2</sub> is weakly soluble in water and thus Henry's law is applicable.

**Properties** The saturation pressure of water at 27°C is 3.568 kPa (Table A-4). Henry's constant for CO<sub>2</sub> dissolved in water at 27°C (300 K) is given in Table 16-2 to be  $H = 1710$  bar. Molar masses of CO<sub>2</sub> and water are 44 and 18 kg/kmol, respectively (Table A-1).

**Analysis** (a) Noting that the CO<sub>2</sub> gas in the bottle is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{\text{sat}@27^\circ\text{C}} = 3.568 \text{ kPa} \quad (\text{more accurate EES value compared to interpolation value from Table A-4})$$

Assuming both CO<sub>2</sub> and vapor to be ideal gases, the mole fraction of water vapor in the CO<sub>2</sub> gas becomes

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.568 \text{ kPa}}{130 \text{ kPa}} = \mathbf{0.0274}$$

(b) Noting that the total pressure is 130 kPa, the partial pressure of CO<sub>2</sub> is

$$P_{\text{CO}_2 \text{ gas}} = P - P_{\text{vapor}} = 130 - 3.568 = 126.4 \text{ kPa} = 1.264 \text{ bar}$$

From Henry's law, the mole fraction of CO<sub>2</sub> in the drink is determined to be

$$y_{\text{CO}_2, \text{liquid side}} = \frac{P_{\text{CO}_2, \text{gas side}}}{H} = \frac{1.264 \text{ bar}}{1710 \text{ bar}} = \mathbf{7.39 \times 10^{-4}}$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{\text{CO}_2, \text{liquid side}} = 1 - 7.39 \times 10^{-4} = 0.9993$$

The mass and mole fractions of a mixture are related to each other by

$$\text{mf}_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO<sub>2</sub> mixture) is

$$M_m = \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{CO}_2} M_{\text{CO}_2} = 0.9993 \times 18.0 + (7.39 \times 10^{-4}) \times 44 = 18.02 \text{ kg / kmol}$$

Then the mass fraction of dissolved CO<sub>2</sub> gas in liquid water becomes

$$\text{mf}_{\text{CO}_2, \text{liquid side}} = y_{\text{CO}_2, \text{liquid side}} (0) \frac{M_{\text{CO}_2}}{M_m} = 7.39 \times 10^{-4} \frac{44}{18.02} = 0.00180$$

Therefore, the mass of dissolved CO<sub>2</sub> in a 300 ml  $\approx$  300 g drink is

$$m_{\text{CO}_2} = \text{mf}_{\text{CO}_2} m_m = (0.00180)(300 \text{ g}) = \mathbf{0.54 \text{ g}}$$

## Review Problems

**16-88** The equilibrium constant of the dissociation process  $\text{O}_2 \leftrightarrow 2\text{O}$  is given in Table A-28 at different temperatures. The value at a given temperature is to be verified using Gibbs function data.

**Analysis** The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{O}} \bar{g}_{\text{O}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{O}} (\bar{h} - T\bar{s})_{\text{O}} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= \nu_{\text{O}} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{O}} - \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &= 2 \times (249,190 + 42,564 - 6852 - 2000 \times 201.135) \\ &\quad - 1 \times (0 + 67,881 - 8682 - 2000 \times 268.655) \\ &= 243,375 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(243,375 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})] = -14.636$$

or

$$K_p = 4.4 \times 10^{-7} \quad (\text{Table A-28: } \ln K_p = -14.622)$$

**16-89** A mixture of  $\text{H}_2$  and Ar is heated until 15% of  $\text{H}_2$  is dissociated. The final temperature of mixture is to be determined.

**Assumptions** 1 The constituents of the mixture are ideal gases. 2 Ar in the mixture remains an inert gas.

**Analysis** The stoichiometric and actual reactions can be written as

Stoichiometric:  $\text{H}_2 \leftrightarrow 2\text{H}$  (thus  $\nu_{\text{H}_2} = 1$  and  $\nu_{\text{H}} = 2$ )

Actual:  $\text{H}_2 + \text{Ar} \longrightarrow \underbrace{0.3\text{H}}_{\text{prod}} + \underbrace{0.85\text{H}_2}_{\text{react.}} + \underbrace{\text{Ar}}_{\text{inert}}$

The equilibrium constant  $K_p$  can be determined from

$$K_p = \frac{N_{\text{H}}^{\nu_{\text{H}}}}{N_{\text{H}_2}^{\nu_{\text{H}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{H}} - \nu_{\text{H}_2}} = \frac{0.3^2}{0.85} \left( \frac{1}{0.85 + 0.3 + 1} \right)^{2-1} = 0.0492$$

From Table A-28, the temperature corresponding to this  $K_p$  value is  $T = 3117 \text{ K}$ .

**16-90** A mixture of  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{N}_2$  is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{O}_2$ ,  $\text{N}_2$  and  $\text{H}_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{H}_2\text{O} \Leftrightarrow \text{H}_2 + \frac{1}{2}\text{O}_2$  (thus  $\nu_{\text{H}_2\text{O}} = 1$ ,  $\nu_{\text{H}_2} = 1$ , and  $\nu_{\text{O}_2} = \frac{1}{2}$ )

Actual:  $\text{H}_2\text{O} + 2\text{O}_2 + 5\text{N}_2 \longrightarrow \underbrace{x\text{H}_2\text{O}}_{\text{react.}} + \underbrace{y\text{H}_2 + z\text{O}_2}_{\text{products}} + \underbrace{5\text{N}_2}_{\text{inert}}$

H balance:  $2 = 2x + 2y \longrightarrow y = 1 - x$

O balance:  $5 = x + 2z \longrightarrow z = 2.5 - 0.5x$

Total number of moles:  $N_{\text{total}} = x + y + z + 5 = 8.5 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} - \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})} = \frac{y}{x} \frac{z^{0.5}}{N_{\text{total}}} \left( \frac{P}{N_{\text{total}}} \right)^{1+0.5-1}$$

From Table A-28,  $\ln K_p = -6.768$  at 2200 K. Thus  $K_p = 0.00115$ . Substituting,

$$0.00115 = \frac{(1-x)(1.5-0.5x)^{0.5}}{x} \left( \frac{5}{8.5-0.5x} \right)^{0.5}$$

Solving for  $x$ ,

$$x = 0.9981$$

Then,

$$y = 1 - x = 0.0019$$

$$z = 2.5 - 0.5x = 2.00095$$

Therefore, the equilibrium composition of the mixture at 2200 K and 5 atm is

The equilibrium constant for the reaction  $\text{H}_2\text{O} \Leftrightarrow \text{OH} + \frac{1}{2}\text{H}_2$  is  $\ln K_p = -7.148$ , which is very close to the  $K_p$  value of the reaction considered. Therefore, it is not realistic to assume that no OH will be present in equilibrium mixture.

|                        |
|------------------------|
| 1 $\text{H}_2\text{O}$ |
| 2 $\text{O}_2$         |
| 5 $\text{N}_2$         |
| 2200 K                 |
| 5 atm                  |

**16-91 [Also solved by EES on enclosed CD]** Methane gas is burned with stoichiometric amount of air during a combustion process. The equilibrium composition and the exit temperature are to be determined.

**Assumptions** 1 The product gases consist of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}$ ,  $\text{N}_2$ , and  $\text{O}_2$ . 2 The constituents of the mixture are ideal gases. 3 This is an adiabatic and steady-flow combustion process.

**Analysis** (a) The combustion equation of  $\text{CH}_4$  with stoichiometric amount of  $\text{O}_2$  can be written as

After combustion, there will be no  $\text{CH}_4$  present in the combustion chamber, and  $\text{H}_2\text{O}$  will act like an inert gas. The equilibrium equation among  $\text{CO}_2$ ,  $\text{CO}$ , and  $\text{O}_2$  can be expressed as

and

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

where

$$N_{\text{total}} = x + (1-x) + (1.5-0.5x) + 2 + 7.52 = 12.02 - 0.5x$$

Substituting,

$$K_p = \frac{(1-x)(0.5-0.5x)^{0.5}}{x} \left( \frac{1}{12.02-0.5x} \right)^{1.5-1}$$

The value of  $K_p$  depends on temperature of the products, which is yet to be determined. A second relation to determine  $K_p$  and  $x$  is obtained from the steady-flow energy balance expressed as

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow 0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since the combustion is adiabatic and the reactants enter the combustion chamber at  $25^\circ\text{C}$ . Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance               | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol |
|-------------------------|------------------------------|-------------------------------------|
| $\text{CH}_4(g)$        | -74,850                      | --                                  |
| $\text{N}_2$            | 0                            | 8669                                |
| $\text{O}_2$            | 0                            | 8682                                |
| $\text{H}_2\text{O}(g)$ | -241,820                     | 9904                                |
| $\text{CO}$             | -110,530                     | 8669                                |
| $\text{CO}_2$           | -393,520                     | 9364                                |

Substituting,

$$\begin{aligned} 0 = & x(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1-x)(-110,530 + \bar{h}_{\text{CO}} - 8669) \\ & + 2(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.5-0.5x)(0 + \bar{h}_{\text{O}_2} - 8682) \\ & + 7.52(0 + \bar{h}_{\text{N}_2} - 8669) - 1(-74,850 + h_{298} - h_{298}) - 0 - 0 \end{aligned}$$

which yields

$$x\bar{h}_{\text{CO}_2} + (1-x)\bar{h}_{\text{CO}} + 2\bar{h}_{\text{H}_2\text{O}} + (0.5-0.5x)\bar{h}_{\text{O}_2} + 7.52\bar{h}_{\text{N}_2} - 279,344x = 617,329$$

Now we have two equations with two unknowns,  $T_p$  and  $x$ . The solution is obtained by trial and error by assuming a temperature  $T_p$ , calculating the equilibrium composition from the first equation, and then checking to see if the second equation is satisfied. A first guess is obtained by assuming there is no CO in the products, i.e.,  $x = 1$ . It yields  $T_p = 2328$  K. The adiabatic combustion temperature with incomplete combustion will be less.

$$\text{Take } T_p = 2300 \text{ K} \longrightarrow \ln K_p = -4.49 \longrightarrow x = 0.870 \longrightarrow RHS = 641,093$$

$$\text{Take } T_p = 2250 \text{ K} \longrightarrow \ln K_p = -4.805 \longrightarrow x = 0.893 \longrightarrow RHS = 612,755$$

By interpolation,

$$T_p = \mathbf{2258 \text{ K}} \text{ and } x = 0.889$$

Thus the composition of the equilibrium mixture is

**16-92 EES Problem 16-91** is reconsidered. The effect of excess air on the equilibrium composition and the exit temperature by varying the percent excess air from 0 to 200 percent is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

"Often, for nonlinear problems such as this one, good gusses are required to start the solution. First, run the program with zero percent excess air to determine the net heat transfer as a function of  $T_{\text{prod}}$ . Just press F3 or click on the Solve Table icon. From Plot Window 1, where  $Q_{\text{net}}$  is plotted vs  $T_{\text{prod}}$ , determine the value of  $T_{\text{prod}}$  for  $Q_{\text{net}}=0$  by holding down the Shift key and move the cross hairs by moving the mouse.  $Q_{\text{net}}$  is approximately zero at  $T_{\text{prod}} = 2269$  K. From Plot Window 2 at  $T_{\text{prod}} = 2269$  K, a, b, and c are approximately 0.89, 0.10, and 0.056, respectively." "For EES to calculate a, b, c, and  $T_{\text{prod}}$  directly for the adiabatic case, remove the '{ }' in the last line of this window to set  $Q_{\text{net}} = 0.0$ . Then from the Options menu select Variable Info and set the Guess Values of a, b, c, and  $T_{\text{prod}}$  to the guess values selected from the Plot Windows. Then press F2 or click on the Calculator icon."

**16-93** The equilibrium constant for the reaction  $\text{CH}_4 + 2\text{O}_2 \Leftrightarrow \text{CO}_2 + 2\text{H}_2\text{O}$  at 100 kPa and 2000 K is to be determined.

**Assumptions 1** The constituents of the mixture are ideal gases.

**Analysis** This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction (Table A-28),

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

$$\ln K_P = \mathbf{32.282}$$

**16-94** The equilibrium mole fraction of the water vapor for the reaction  $\text{CH}_4 + 2\text{O}_2 \rightleftharpoons \text{CO}_2 + 2\text{H}_2\text{O}$  at 100 kPa and 2000 K is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CH}_4$ ,  $\text{O}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$ . 2 The constituents of the mixture are ideal gases.

**Analysis** This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction,

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

$$\ln K_P = 32.282$$

C balance:  $1 = x + z \longrightarrow z = 1 - x$

H balance:  $4 = 4x + 2m \longrightarrow m = 2 - 2x$

O balance:  $4 = 2y + 2z + m \longrightarrow y = 2x$

Total number of moles:  $N_{\text{total}} = x + y + z + m = 3$

The equilibrium constant relation can be expressed as

$$K_P = \frac{N_{\text{CO}_2}^{V_{\text{CO}_2}} N_{\text{H}_2\text{O}}^{V_{\text{H}_2\text{O}}}}{N_{\text{CH}_4}^{V_{\text{CH}_4}} N_{\text{O}_2}^{V_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{V_{\text{CO}_2} + V_{\text{H}_2\text{O}} - V_{\text{CH}_4} - V_{\text{O}_2}}$$

Substituting,

$$e^{32.282} = \frac{(1-x)(2-2x)^2}{x(2x)^2} \left( \frac{100/101.325}{3} \right)^{1+2-1-2}$$

Solving for  $x$ ,

$$x = 0.00002122$$

Then,

$$y = 2x = 0.00004244$$

$$z = 1 - x = 0.99997878$$

$$m = 2 - 2x = 1.99995756$$

Therefore, the equilibrium composition of the mixture at 2000 K and 100 kPa is

$$0.00002122 \text{ CH}_4 + 0.00004244 \text{ O}_2 + 0.99997878 \text{ CO}_2 + 1.99995756 \text{ H}_2\text{O}$$

The mole fraction of water vapor is then

$$y_{\text{H}_2\text{O}} = \frac{1.99995756}{3} = \mathbf{0.6667}$$

**16-95** The equilibrium partial pressure of the carbon dioxide for the reaction  $\text{CH}_4 + 2\text{O}_2 \rightleftharpoons \text{CO}_2 + 2\text{H}_2\text{O}$  at 700 kPa and 3000 K is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CH}_4$ ,  $\text{O}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$ . 2 The constituents of the mixture are ideal gases.

**Analysis** This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction,

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

$$\ln K_p = 12.356$$

C balance:  $1 = x + z \longrightarrow z = 1 - x$

H balance:  $4 = 4x + 2m \longrightarrow m = 2 - 2x$

O balance:  $4 = 2y + 2z + m \longrightarrow y = 2x$

Total number of moles:  $N_{\text{total}} = x + y + z + m = 3$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{v_{\text{CO}_2}} N_{\text{H}_2\text{O}}^{v_{\text{H}_2\text{O}}}}{N_{\text{CH}_4}^{v_{\text{CH}_4}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{v_{\text{CO}_2} + v_{\text{H}_2\text{O}} - v_{\text{CH}_4} - v_{\text{O}_2}}$$

Substituting,

$$e^{12.356} = \frac{(1-x)(2-2x)^2}{x(2x)^2} \left( \frac{700/101.325}{3} \right)^{1+2-1-2}$$

Solving for  $x$ ,

$$x = 0.01601$$

Then,

$$y = 2x = 0.03202$$

$$z = 1 - x = 0.98399$$

$$m = 2 - 2x = 1.96798$$

Therefore, the equilibrium composition of the mixture at 3000 K and 700 kPa is

The mole fraction of carbon dioxide is

$$y_{\text{CO}_2} = \frac{0.98399}{3} = 0.3280$$

and the partial pressure of the carbon dioxide in the product mixture is

$$P_{\text{CO}_2} = y_{\text{CO}_2} P = (0.3280)(700 \text{ kPa}) = \mathbf{230 \text{ kPa}}$$

**16-96** Methane is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

**Properties** The molar mass and gas constant of methane are 16.043 kg/kmol and 0.5182 kJ/kg·K (Table A-1).

**Assumptions** 1 The equilibrium composition consists of O<sub>2</sub> and O. 2 The constituents of the mixture are ideal gases.

**Analysis** (a) An energy balance for the process gives

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$Q_{\text{in}} = N(\bar{u}_2 - \bar{u}_1)$$

$$= N[\bar{h}_2 - \bar{h}_1 - R_u(T_2 - T_1)]$$

Using the empirical coefficients of Table A-2c,

$$\begin{aligned}\bar{h}_2 - \bar{h}_1 &= \int_1^2 c_p dT = a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 19.89(1000 - 298) + \frac{0.05024}{2}(1000^2 - 298^2) + \frac{1.269 \times 10^{-5}}{3}(1000^3 - 298^3) \\ &\quad + \frac{-11.01 \times 10^{-9}}{4}(1000^4 - 298^4) \\ &= 38,239 \text{ kJ/kmol}\end{aligned}$$

Substituting,

$$Q_{\text{in}} = (10 \text{ kmol})[38,239 \text{ kJ/kmol} - (8.314 \text{ kJ/kmol} \cdot \text{K})(1000 - 298)\text{K}] = \mathbf{324,000 \text{ kJ}}$$

(b) The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{CH}_4 \Leftrightarrow \text{C} + 2\text{H}_2$  (thus  $\nu_{\text{CH}_4} = 1$ ,  $\nu_{\text{C}} = 1$  and  $\nu_{\text{H}_2} = 2$ )

Actual:  $\text{CH}_4 \longrightarrow \underbrace{x\text{CH}_4}_{\text{react.}} + \underbrace{y\text{C} + z\text{H}_2}_{\text{products}}$

C balance:  $1 = x + y \longrightarrow y = 1 - x$

H balance:  $4 = 4x + 2z \longrightarrow z = 2 - 2x$

Total number of moles:  $N_{\text{total}} = x + y + z = 3 - 2x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{H}_2}^{\nu_{\text{H}_2}}}{N_{\text{CH}_4}^{\nu_{\text{CH}_4}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{C}} + \nu_{\text{H}_2} - \nu_{\text{CH}_4}}$$

From the problem statement, at 1000 K,  $\ln K_p = -2.328$ . Then,

$$K_p = e^{-2.328} = 0.09749$$

Substituting,

$$0.09749 = \frac{(1-x)(2-2x)^2}{x} \left( \frac{1}{3-2x} \right)^{1+2-1}$$

Solving for  $x$ ,

$$x = 0.6414$$

Then,

$$y = 1 - x = 0.3586$$

$$z = 2 - 2x = 0.7172$$

Therefore, the equilibrium composition of the mixture at 1000 K and 1 atm is

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_{\text{total}}} = \frac{0.6414}{0.6414 + 0.3586 + 0.7172} = \frac{0.6414}{1.7172} = 0.3735$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_{\text{total}}} = \frac{0.3586}{1.7172} = 0.2088$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{0.7172}{1.7172} = 0.4177$$

The heat transfer can be determined from

$$\begin{aligned} Q_{\text{in}} &= N(y_{\text{CH}_4}c_{\nu,\text{CH}_4}T_2 + y_{\text{H}_2}c_{\nu,\text{H}_2}T_2 + y_{\text{C}}c_{\nu,\text{C}}T_2) - Nc_{\nu,\text{CH}_4}T_1 \\ &= (10)[(0.3735)(63.3)(1000) + (0.4177)(21.7)(1000) + (0.2088)(0.711)(1000)] - (10)(27.8)(298) \\ &= \mathbf{245,700 \text{ kJ}} \end{aligned}$$

**16-97** Solid carbon is burned with a stoichiometric amount of air. The number of moles of  $\text{CO}_2$  formed per mole of carbon is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{N}_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** Inspection of Table A-28 reveals that the dissociation equilibrium constants of  $\text{CO}_2$ ,  $\text{O}_2$ , and  $\text{N}_2$  are quite small and therefore may be neglected. (We learned from another source that the equilibrium constant for  $\text{CO}$  is also small). The combustion is then complete and the reaction is described by

Carbon + Air  
25°C

The number of moles of  $\text{CO}_2$  in the products is then

$$\frac{N_{\text{CO}_2}}{N_{\text{C}}} = 1$$

**16-98** Solid carbon is burned with a stoichiometric amount of air. The amount of heat released per kilogram of carbon is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{N}_2$ . 2 The constituents of the mixture are ideal gases.

**Analysis** Inspection of Table A-28 reveals that the dissociation equilibrium constants of  $\text{CO}_2$ ,  $\text{O}_2$ , and  $\text{N}_2$  are quite small and therefore may be neglected. (We learned from another source that the equilibrium constant for  $\text{CO}$  is also small). The combustion is then complete and the reaction is described by

Carbon + Air  
25°C

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance     | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{1000\text{K}}$<br>kJ/kmol |
|---------------|------------------------------|------------------------------------|-------------------------------------|
| $\text{N}_2$  | 0                            | 8669                               | 30,129                              |
| $\text{CO}_2$ | -393,520                     | 9364                               | 42,769                              |

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 42,769 - 9364) + (3.76)(0 + 30,129 - 8669) \\ &= -279,400 \text{ kJ/kmol C} \end{aligned}$$

or 
$$Q_{\text{out}} = \frac{279,400 \text{ kJ/kmol}}{12 \text{ kg/kmol}} = \mathbf{23,280 \text{ kJ/kg C}}$$

**16-99** Methane gas is burned with 30 percent excess air. The equilibrium composition of the products of combustion and the amount of heat released by this combustion are to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ ,  $\text{NO}$ , and  $\text{N}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** Inspection of the equilibrium constants of the possible reactions indicate that only the formation of  $\text{NO}$  need to be considered in addition to other complete combustion products. Then, the stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$  (thus  $\nu_{\text{N}_2} = 1$ ,  $\nu_{\text{O}_2} = 1$ , and  $\nu_{\text{NO}} = 2$ )

Actual:  $\text{CH}_4 + 2.6(\text{O}_2 + 3.76\text{N}_2) \longrightarrow \text{CO}_2 + 2\text{H}_2\text{O} + x\text{NO} + y\text{O}_2 + z\text{N}_2$

N balance:  $9.776 = x + 2z \longrightarrow z = 4.888 - 0.5x$

O balance:  $5.2 = 2 + 2 + x + 2y \longrightarrow y = 0.6 - 0.5x$

Total number of moles:  $N_{\text{total}} = 1 + 2 + x + y + z = 8.488$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 1600 K,  $\ln K_p = -5.294$ .

Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 5.294) = 2.522 \times 10^{-5}$$

Substituting,

$$2.522 \times 10^{-5} = \frac{x^2}{(0.6 - 0.5x)(4.888 - 0.5x)} \left( \frac{1}{8.488} \right)^{2-1-1}$$

Solving for  $x$ ,

$$x = 0.008566$$

Then,

$$y = 0.6 - 0.5x = 0.5957$$

$$z = 4.888 - 0.5x = 4.884$$

Therefore, the equilibrium composition of the products mixture at 1600 K and 1 atm is

The heat transfer for this combustion process is determined from the energy balance  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance            | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{1600\text{K}}$<br>kJ/kmol |
|----------------------|------------------------------|------------------------------------|-------------------------------------|
| $\text{CH}_4$        | -74,850                      | ---                                | ---                                 |
| $\text{O}_2$         | 0                            | 8682                               | 52,961                              |
| $\text{N}_2$         | 0                            | 8669                               | 50,571                              |
| $\text{H}_2\text{O}$ | -241,820                     | 9904                               | 62,748                              |
| $\text{CO}_2$        | -393,520                     | 9364                               | 76,944                              |

Neglecting the effect of  $\text{NO}$  in the energy balance and substituting,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 76,944 - 9364) + (2)(-241,820 + 62,748 - 9904) + 0.5957(52,961 - 8682) \\ &\quad + (4.884)(50,571 - 8669) - (-74,850) \\ &= -472,900 \text{ kJ/kmol CH}_4 \end{aligned}$$

or  $Q_{\text{out}} = 472,900 \text{ kJ/kmol CH}_4$

**16-100** Propane gas is burned with 30% excess air. The equilibrium composition of the products of combustion and the amount of heat released by this combustion are to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ ,  $\text{NO}$ , and  $\text{N}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis (a)** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$  (thus  $\nu_{\text{N}_2} = 1$ ,  $\nu_{\text{O}_2} = 1$ , and  $\nu_{\text{NO}} = 2$ )

Actual:  $\text{C}_3\text{H}_8 + 1.3 \times 5(\text{O}_2 + 3.76\text{N}_2) \longrightarrow 3\text{CO}_2 + 4\text{H}_2\text{O} + x\text{NO} + y\text{O}_2 + z\text{N}_2$

N balance:  $48.88 = x + 2z \longrightarrow z = 24.44 - 0.5x$

O balance:  $13 = 6 + 4 + x + 2y \longrightarrow y = 1.5 - 0.5x$

Total number of moles:  $N_{\text{total}} = 3 + 4 + x + y + z = 32.94$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 1600 K,  $\ln K_p = -5.294$ .

Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 5.294) = 2.522 \times 10^{-5}$$

Substituting,

$$2.522 \times 10^{-5} = \frac{x^2}{(1.5 - 0.5x)(24.44 - 0.5x)} \left( \frac{1}{32.94} \right)^{2-1-1}$$

Solving for  $x$ ,

$$x = 0.03024$$

Then,

$$y = 1.5 - 0.5x = 1.485$$

$$z = 24.44 - 0.5x = 24.19$$

Therefore, the equilibrium composition of the products mixture at 1600 K and 1 atm is

(b) The heat transfer for this combustion process is determined from the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  applied on the combustion chamber with  $W = 0$ . It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance              | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{K}}$<br>kJ/kmol | $\bar{h}_{1600\text{K}}$<br>kJ/kmol |
|------------------------|------------------------------|------------------------------------|-------------------------------------|
| $\text{C}_3\text{H}_8$ | -103,850                     | ---                                | ---                                 |
| $\text{O}_2$           | 0                            | 8682                               | 52,961                              |
| $\text{N}_2$           | 0                            | 8669                               | 50,571                              |
| $\text{H}_2\text{O}$   | -241,820                     | 9904                               | 62,748                              |
| $\text{CO}_2$          | -393,520                     | 9364                               | 76,944                              |

Neglecting the effect of NO in the energy balance and substituting,

$$\begin{aligned} -Q_{\text{out}} &= (3)(-393,520 + 76,944 - 9364) + (4)(-241,820 + 62,748 - 9904) + 1.485(52,961 - 8682) \\ &\quad + (24.19)(50,571 - 8669) - (-103,850) \\ &= -654,360 \text{ kJ/kmol C}_3\text{H}_8 \end{aligned}$$

$$\text{or } Q_{\text{out}} = \frac{654,360 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = \mathbf{14,870 \text{ kJ/kg C}_3\text{H}_8}$$

**16-101E** Gaseous octane gas is burned with 40% excess air. The equilibrium composition of the products of combustion is to be determined.

**Assumptions 1** The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ ,  $\text{NO}$ , and  $\text{N}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** The stoichiometric and actual reactions in this case are

Stoichiometric:  $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$  (thus  $\nu_{\text{N}_2} = 1$ ,  $\nu_{\text{O}_2} = 1$ , and  $\nu_{\text{NO}} = 2$ )

Actual:  $\text{C}_8\text{H}_{18} + 1.4 \times 12.5(\text{O}_2 + 3.76\text{N}_2) \longrightarrow 8\text{CO}_2 + 9\text{H}_2\text{O} + x\text{NO} + y\text{O}_2 + z\text{N}_2$

N balance:  $131.6 = x + 2z \longrightarrow z = 65.8 - 0.5x$

O balance:  $35 = 16 + 9 + x + 2y \longrightarrow y = 5 - 0.5x$

Total number of moles:  $N_{\text{total}} = 8 + 9 + x + y + z = 87.8$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 2000 K (3600 R),  $\ln K_p = -3.931$ . Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 3.931) = 3.851 \times 10^{-4}$$

Substituting,

$$3.851 \times 10^{-4} = \frac{x^2}{(5 - 0.5x)(65.8 - 0.5x)} \left( \frac{600/14.7}{87.8} \right)^{2-1-1}$$

Solving for  $x$ ,

$$x = 0.1119$$

Then,

$$y = 5 - 0.5x = 4.944$$

$$z = 65.8 - 0.5x = 65.74$$

Therefore, the equilibrium composition of the products mixture at 3600 R and 600 psia is

**16-102** A mixture of  $\text{H}_2\text{O}$  and  $\text{O}_2$  is heated to a high temperature. The equilibrium composition is to be determined.

**Assumptions** **1** The equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{OH}$ ,  $\text{O}_2$ , and  $\text{H}_2$ . **2** The constituents of the mixture are ideal gases.

**Analysis** The reaction equation during this process can be expressed as

$\text{H}_2\text{O}$ ,  $\text{OH}$ ,  $\text{H}_2$ ,  $\text{O}_2$   
3600 K  
8 atm

Mass balances for hydrogen and oxygen yield

H balance:  $4 = 2x + 2y + w$  (1)

O balance:  $8 = x + 2z + w$  (2)

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_P$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3600 K are determined from Table A-28 to be

$$\ln K_{P1} = -1.392 \longrightarrow K_{P1} = 0.24858$$

$$\ln K_{P2} = -1.088 \longrightarrow K_{P2} = 0.33689$$

The  $K_P$  relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

$$K_{P2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

where

$$N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.24858 = \frac{(y)(z)^{1/2}}{x} \left( \frac{8}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.33689 = \frac{(w)(y)^{1/2}}{x} \left( \frac{8}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 1.371 \quad y = 0.1646 \quad z = 2.85 \quad w = 0.928$$

Therefore, the equilibrium composition becomes

**16-103** A mixture of  $\text{CO}_2$  and  $\text{O}_2$  is heated to a high temperature. The equilibrium composition is to be determined.

**Assumptions** 1 The equilibrium composition consists of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{O}_2$ , and  $\text{O}$ . 2 The constituents of the mixture are ideal gases.

**Analysis** The reaction equation during this process can be expressed as

$\text{CO}_2, \text{CO}, \text{O}_2, \text{O}$   
3400 K  
2 atm

Mass balances for carbon and oxygen yield

C balance:  $3 = x + y$  (1)

O balance:  $12 = 2x + y + 2z + w$  (2)

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the  $K_P$  relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3400 K are determined from Table A-28 to be

$$\ln K_{P1} = 0.169 \longrightarrow K_{P1} = 1.1841$$

$$\ln K_{P2} = -1.935 \longrightarrow K_{P2} = 0.1444$$

The  $K_P$  relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

$$K_{P2} = \frac{N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left( \frac{P}{N_{\text{total}}} \right)^{\nu_{\text{O}} - \nu_{\text{O}_2}}$$

where

$$N_{\text{total}} = N_{\text{CO}_2} + N_{\text{O}_2} + N_{\text{CO}} + N_{\text{O}} = x + y + z + w$$

Substituting,

$$1.1841 = \frac{(y)(z)^{1/2}}{x} \left( \frac{2}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.1444 = \frac{w^2}{z} \left( \frac{2}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns  $x$ ,  $y$ ,  $z$ , and  $w$  yields

$$x = 1.313 \quad y = 1.687 \quad z = 3.187 \quad w = 1.314$$

Thus the equilibrium composition is

**16-104 EES** Problem 16-103 is reconsidered. The effect of pressure on the equilibrium composition by varying pressure from 1 atm to 10 atm is to be studied.

**Analysis** The problem is solved using EES, and the solution is given below.

"For EES to calculate a, b, c, and d at T<sub>prod</sub> and P<sub>prod</sub> press F2 or click on the Calculator icon. The EES results using the built in function data is not the same as the answers provided with the problem. However, if we supply the K<sub>P</sub>'s from Table A-28 to EES, the results are equal to the answer provided. The plot of moles CO vs. P<sub>atm</sub> was done with the EES property data."

"Input Data"

P<sub>atm</sub> = 2 [atm]  
 P<sub>prod</sub> = P<sub>atm</sub> \* 101.3  
 R<sub>u</sub> = 8.314 [kJ/kmol-K]  
 T<sub>prod</sub> = 3400 [K]  
 P = P<sub>atm</sub>

**16-105** The  $\bar{h}_R$  at a specified temperature is to be determined using enthalpy and  $K_p$  data.

**Assumptions** Both the reactants and products are ideal gases.

**Analysis** (a) The complete combustion equation of  $H_2$  can be expressed as

The  $\bar{h}_R$  of the combustion process of  $H_2$  at 2400 K is the amount of energy released as one kmol of  $H_2$  is burned in a steady-flow combustion chamber at a temperature of 2400 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the  $H_2O$ ,  $H_2$ , and  $O_2$  to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{2400\text{ K}}$<br>kJ/kmol |
|-----------|------------------------------|-------------------------------------|--------------------------------------|
| $H_2O$    | -241,820                     | 9904                                | 103,508                              |
| $H_2$     | 0                            | 8468                                | 75,383                               |
| $O_2$     | 0                            | 8682                                | 83,174                               |

Substituting,

$$\begin{aligned}\bar{h}_R &= 1(-241,820 + 103,508 - 9904) \\ &\quad - 1(0 + 75,383 - 8468) \\ &\quad - 0.5(0 + 83,174 - 8682) \\ &= \mathbf{-252,377\text{ kJ/kmol}}\end{aligned}$$

(b) The  $\bar{h}_R$  value at 2400 K can be estimated by using  $K_p$  values at 2200 K and 2600 K (the closest two temperatures to 2400 K for which  $K_p$  data are available) from Table A-28,

$$\begin{aligned}\ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \\ 4.648 - 6.768 &\cong \frac{\bar{h}_R}{8.314\text{ kJ/kmol} \cdot \text{K}} \left( \frac{1}{2200\text{ K}} - \frac{1}{2600\text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{-252,047\text{ kJ/kmol}}\end{aligned}$$

**16-106 EES** Problem 16-105 is reconsidered. The effect of temperature on the enthalpy of reaction using both methods by varying the temperature from 2000 to 3000 K is to be investigated.

**Analysis** The problem is solved using EES, and the solution is given below.

**"Input Data"**

```
T_prod=2400 [K]
DELTA_T_prod =25 [K]
R_u=8.314 [kJ/kmol-K]
T_prod_1 = T_prod - DELTA_T_prod
T_prod_2 = T_prod + DELTA_T_prod
```

| 0.0000405         | 3000                  | -253142                          | -253142                    |

**16-107** The  $K_P$  value of the dissociation process  $\text{O}_2 \rightleftharpoons 2\text{O}$  at a specified temperature is to be determined using the  $\bar{h}_R$  data and  $K_P$  value at a specified temperature.

**Assumptions** Both the reactants and products are ideal gases.

**Analysis** The  $\bar{h}_R$  and  $K_P$  data are related to each other by

$$\ln \frac{K_{P2}}{K_{P1}} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

The  $\bar{h}_R$  of the specified reaction at 2800 K is the amount of energy released as one kmol of  $\text{O}_2$  dissociates in a steady-flow combustion chamber at a temperature of 2800 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the  $\text{O}_2$  and  $\text{O}$  to be ideal gases, we have  $h = h(T)$ . From the tables,

| Substance    | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{2800\text{ K}}$<br>kJ/kmol |
|--------------|------------------------------|-------------------------------------|--------------------------------------|
| O            | 249,190                      | 6852                                | 59,241                               |
| $\text{O}_2$ | 0                            | 8682                                | 98,826                               |

Substituting,

$$\begin{aligned} \bar{h}_R &= 2(249,190 + 59,241 - 6852) - 1(0 + 98,826 - 8682) \\ &= 513,014 \text{ kJ / kmol} \end{aligned}$$

The  $K_P$  value at 3000 K can be estimated from the equation above by using this  $\bar{h}_R$  value and the  $K_P$  value at 2600 K which is  $\ln K_{P1} = -7.521$ ,

$$\ln K_{P2} - (-7.521) = \frac{513,014 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left( \frac{1}{2600 \text{ K}} - \frac{1}{3000 \text{ K}} \right)$$

$$\ln K_{P2} = -4.357 \quad (\text{Table A - 28: } \ln K_{P2} = -4.357)$$

or

$$K_{P2} = \mathbf{0.0128}$$

**16-108** It is to be shown that when the three phases of a pure substance are in equilibrium, the specific Gibbs function of each phase is the same.

**Analysis** The total Gibbs function of the three phase mixture of a pure substance can be expressed as

$$G = m_s g_s + m_\ell g_\ell + m_g g_g$$

where the subscripts  $s$ ,  $\ell$ , and  $g$  indicate solid, liquid and gaseous phases. Differentiating by holding the temperature and pressure (thus the Gibbs functions,  $g$ ) constant yields

$$dG = g_s dm_s + g_\ell dm_\ell + g_g dm_g$$

From conservation of mass,

$$dm_s + dm_\ell + dm_g = 0 \quad \longrightarrow \quad dm_s = -dm_\ell - dm_g$$

Substituting,

$$dG = -g_s(dm_\ell + dm_g) + g_\ell dm_\ell + g_g dm_g$$

Rearranging,

$$dG = (g_\ell - g_s)dm_\ell + (g_g - g_s)dm_g$$

For equilibrium,  $dG = 0$ . Also  $dm_\ell$  and  $dm_g$  can be varied independently. Thus each term on the right hand side must be zero to satisfy the equilibrium criteria. It yields

$$g_\ell = g_s \quad \text{and} \quad g_g = g_s$$

Combining these two conditions gives the desired result,

$$g_\ell = g_s = g_g$$

**16-109** It is to be shown that when the two phases of a two-component system are in equilibrium, the specific Gibbs function of each phase of each component is the same.

**Analysis** The total Gibbs function of the two phase mixture can be expressed as

$$G = (m_{\ell 1}g_{\ell 1} + m_{g1}g_{g1}) + (m_{\ell 2}g_{\ell 2} + m_{g2}g_{g2})$$

where the subscripts  $\ell$  and  $g$  indicate liquid and gaseous phases. Differentiating by holding the temperature and pressure (thus the Gibbs functions) constant yields

$$dG = g_{\ell 1}dm_{\ell 1} + g_{g1}dm_{g1} + g_{\ell 2}dm_{\ell 2} + g_{g2}dm_{g2}$$

From conservation of mass,

$$dm_{g1} = -dm_{\ell 1} \quad \text{and} \quad dm_{g2} = -dm_{\ell 2}$$

Substituting,

$$dG = (g_{\ell 1} - g_{g1})dm_{\ell 1} + (g_{\ell 2} - g_{g2})dm_{\ell 2}$$

For equilibrium,  $dG = 0$ . Also  $dm_{\ell 1}$  and  $dm_{\ell 2}$  can be varied independently. Thus each term on the right hand side must be zero to satisfy the equilibrium criteria. Then we have

$$g_{\ell 1} = g_{g1} \quad \text{and} \quad g_{\ell 2} = g_{g2}$$

which is the desired result.

**16-110** A mixture of CO and O<sub>2</sub> contained in a tank is ignited. The final pressure in the tank and the amount of heat transfer are to be determined.

**Assumptions** 1 The equilibrium composition consists of CO<sub>2</sub> and O<sub>2</sub>. 2 Both the reactants and the products are ideal gases.

**Analysis** The combustion equation can be written as

CO<sub>2</sub>, CO, O<sub>2</sub>  
25°C  
2 atm

The heat transfer can be determined from

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Both the reactants and the products are assumed to be ideal gases, and thus all the internal energy and enthalpies depend on temperature only, and the  $P\bar{v}$  terms in this equation can be replaced by  $R_u T$ . It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{500\text{ K}} - \bar{h}_{298\text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since reactants are at the standard reference temperature of 25°C. From the tables,

| Substance       | $\bar{h}_f^\circ$<br>kJ/kmol | $\bar{h}_{298\text{ K}}$<br>kJ/kmol | $\bar{h}_{500\text{ K}}$<br>kJ/kmol |
|-----------------|------------------------------|-------------------------------------|-------------------------------------|
| CO              | -110,530                     | 8669                                | 14,600                              |
| O <sub>2</sub>  | 0                            | 8682                                | 14,770                              |
| CO <sub>2</sub> | -393,520                     | 9364                                | 17,678                              |

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= 1(-393,520 + 17,678 - 9364 - 8.314 \times 500) \\ &\quad + 2.5(0 + 14,770 - 8682 - 8.314 \times 500) \\ &\quad - 3(0 - 8.314 \times 298) \\ &\quad - 1(-110,530 - 8.314 \times 298) \\ &= -264,095 \text{ kJ/kmol CO} \end{aligned}$$

or

$$Q_{\text{out}} = 264,095 \text{ kJ/kmol CO}$$

The final pressure in the tank is determined from

$$\frac{P_1 V}{P_2 V} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{3.5}{4} \times \frac{500\text{ K}}{298\text{ K}} (2\text{ atm}) = 2.94\text{ atm}$$

The equilibrium constant for the reaction  $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$  is  $\ln K_P = 57.62$ , which is much greater than 7. Therefore, it is not realistic to assume that no CO will be present in equilibrium mixture.

**16-111** Using Henry's law, it is to be shown that the dissolved gases in a liquid can be driven off by heating the liquid.

**Analysis** Henry's law is expressed as

$$y_{i, \text{ liquid side}}(0) = \frac{P_{i, \text{ gas side}}(0)}{H}$$

Henry's constant  $H$  increases with temperature, and thus the fraction of gas  $i$  in the liquid  $y_{i, \text{ liquid side}}$  decreases. Therefore, heating a liquid will drive off the dissolved gases in a liquid.

**16-112** A 2-L bottle is filled with carbonated drink that is fully charged (saturated) with CO<sub>2</sub> gas. The volume that the CO<sub>2</sub> gas would occupy if it is released and stored in a container at room conditions is to be determined.

**Assumptions** 1 The liquid drink can be treated as water. 2 Both the CO<sub>2</sub> gas and the water vapor are ideal gases. 3 The CO<sub>2</sub> gas is weakly soluble in water and thus Henry's law is applicable.

**Properties** The saturation pressure of water at 17°C is 1.938 kPa (Table A-4). Henry's constant for CO<sub>2</sub> dissolved in water at 17°C (290 K) is  $H = 1280$  bar (Table 16-2). Molar masses of CO<sub>2</sub> and water are 44.01 and 18.015 kg/kmol, respectively (Table A-1). The gas constant of CO<sub>2</sub> is 0.1889 kPa·m<sup>3</sup>/kg·K. Also, 1 bar = 100 kPa.

**Analysis** In the charging station, the CO<sub>2</sub> gas and water vapor mixture above the liquid will form a saturated mixture. Noting that the saturation pressure of water at 17°C is 1.938 kPa, the partial pressure of the CO<sub>2</sub> gas is

$$P_{\text{CO}_2, \text{gas side}} = P - P_{\text{vapor}} = P - P_{\text{sat @ 17°C}} = 600 - 1.938 = 598.06 \text{ kPa} = 5.9806 \text{ bar}$$

From Henry's law, the mole fraction of CO<sub>2</sub> in the liquid drink is determined to be

$$y_{\text{CO}_2, \text{liquid side}} = \frac{P_{\text{CO}_2, \text{gas side}}}{H} = \frac{5.9806 \text{ bar}}{1280 \text{ bar}} = 0.00467$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{\text{CO}_2, \text{liquid side}} = 1 - 0.00467 = 0.99533$$

The mass and mole fractions of a mixture are related to each other by

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO<sub>2</sub> mixture) is

$$\begin{aligned} M_m &= \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{CO}_2} M_{\text{CO}_2} \\ &= 0.99533 \times 18.015 + 0.00467 \times 44.01 = 18.14 \text{ kg/kmol} \end{aligned}$$

Then the mass fraction of dissolved CO<sub>2</sub> in liquid drink becomes

$$w_{\text{CO}_2, \text{liquid side}} = y_{\text{CO}_2, \text{liquid side}} \frac{M_{\text{CO}_2}}{M_m} = 0.00467 \frac{44.01}{18.14} = 0.0113$$

Therefore, the mass of dissolved CO<sub>2</sub> in a 2 L ≈ 2 kg drink is

$$m_{\text{CO}_2} = w_{\text{CO}_2} m_m = 0.0113(2 \text{ kg}) = 0.0226 \text{ kg}$$

Then the volume occupied by this CO<sub>2</sub> at the room conditions of 20°C and 100 kPa becomes

$$\nu = \frac{mRT}{P} = \frac{(0.0226 \text{ kg})(0.1889 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{100 \text{ kPa}} = \mathbf{0.0125 \text{ m}^3 = 12.5 \text{ L}}$$

**Discussion** Note that the amount of dissolved CO<sub>2</sub> in a 2-L pressurized drink is large enough to fill 6 such bottles at room temperature and pressure. Also, we could simplify the calculations by assuming the molar mass of carbonated drink to be the same as that of water, and take it to be 18 kg/kmol because of the very low mole fraction of CO<sub>2</sub> in the drink.

**16-113 EES** Ethyl alcohol  $\text{C}_2\text{H}_5\text{OH}$  (gas) is burned in a steady-flow adiabatic combustion chamber with 40 percent excess air. The adiabatic flame temperature of the products is to be determined and the adiabatic flame temperature as a function of the percent excess air is to be plotted.

**Analysis** The complete combustion reaction in this case can be written as

where  $a_{\text{th}}$  is the stoichiometric coefficient for air. The oxygen balance gives

$$1 + (1 + Ex)a_{\text{th}} \times 2 = 2 \times 2 + 3 \times 1 + (Ex)(a_{\text{th}}) \times 2$$

The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

Carbon balance:  $2 = a + b$

Hydrogen balance:  $6 = 2d \longrightarrow d = 3$

Oxygen balance:  $1 + (1 + Ex)a_{\text{th}} \times 2 = a \times 2 + b + d + e \times 2$

Nitrogen balance:  $(1 + Ex)a_{\text{th}} \times 3.76 = f$

Solving the above equations, we find the coefficients to be

$$Ex = 0.4, a_{\text{th}} = 3, a = 1.995, b = 0.004938, d = 3, e = 1.202, f = 15.79$$

Then, we write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 1.995 + 0.004938 + 3 + 1.202 + 15.79 = 21.99$$

The assumed equilibrium reaction is

The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{\text{CO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}_2}$$

The equilibrium constant is also given by

$$K_p = \frac{b e^{0.5}}{a} \left( \frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{(0.004938)(1.202)^{0.5}}{1.995} \left( \frac{1}{21.99} \right)^{0.5} = 0.0005787$$

A steady flow energy balance gives

$$H_R = H_P$$

where

$$\begin{aligned} H_R &= \bar{h}_{f_{\text{fuel}@25^\circ\text{C}}}^\circ + 4.2\bar{h}_{\text{O}_2@25^\circ\text{C}} + 15.79\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= (-235,310 \text{ kJ/kmol}) + 4.2(0) + 15.79(0) = -235,310 \text{ kJ/kmol} \end{aligned}$$

$$H_P = 1.995\bar{h}_{\text{CO}_2@T_{\text{prod}}} + 0.004938\bar{h}_{\text{CO}@T_{\text{prod}}} + 3\bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} + 1.202\bar{h}_{\text{O}_2@T_{\text{prod}}} + 15.79\bar{h}_{\text{N}_2@T_{\text{prod}}}$$

Solving the energy balance equation using EES, we obtain the adiabatic flame temperature to be

$$T_{\text{prod}} = \mathbf{1907 \text{ K}}$$

**16-114 EES** The percent theoretical air required for the combustion of octane such that the volume fraction of CO in the products is less than 0.1% and the heat transfer are to be determined. Also, the percent theoretical air required for 0.1% CO in the products as a function of product pressure is to be plotted.

**Analysis** The complete combustion reaction equation for excess air is

The oxygen balance is

$$P_{\text{th}} a_{\text{th}} \times 2 = 8 \times 2 + 9 \times 1 + (P_{\text{th}} - 1)a_{\text{th}} \times 2$$

The reaction equation for excess air and products in equilibrium is

The coefficients are to be determined from the mass balances

Carbon balance:  $8 = a + b$

Hydrogen balance:  $18 = 2d \longrightarrow d = 9$

Oxygen balance:  $P_{\text{th}} a_{\text{th}} \times 2 = a \times 2 + b + d + e \times 2$

Nitrogen balance:  $P_{\text{th}} a_{\text{th}} \times 3.76 = f$

Volume fraction of CO must be less than 0.1%. That is,

$$y_{\text{CO}} = \frac{b}{N_{\text{tot}}} = \frac{b}{a + b + d + e + f} = 0.001$$

The assumed equilibrium reaction is

The  $K_p$  value of a reaction at a specified temperature can be determined from the Gibbs function data:

$$\bar{g}_{\text{CO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}} = (-53,826) - (2000)(258.48) = -570,781 \text{ kJ/kmol}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2} = (59,193) - (2000)(268.53) = -477,876 \text{ kJ/kmol}$$

$$\bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}_2} = (-302,128) - (2000)(309.00) = -920,121 \text{ kJ/kmol}$$

The enthalpies at 2000 K and entropies at 2000 K and 101.3 kPa are obtained from EES. Substituting,

$$\begin{aligned} \Delta G^*(T_{\text{prod}}) &= \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) \\ &= 1(-570,781) + 0.5(-477,876) - (-920,121) = 110,402 \text{ kJ/kmol} \end{aligned}$$

$$K_p = \exp\left(\frac{-\Delta G^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right) = \exp\left(\frac{-110,402}{(8.314)(2000)}\right) = 0.001308$$

The equilibrium constant is also given by

$$K_p = \frac{b e^{0.5}}{a} \left(\frac{P}{N_{\text{tot}}}\right)^{1+0.5-1} = \frac{b e^{0.5}}{a} \left(\frac{P_{\text{prod}}/101.3}{a + b + d + e + f}\right)^{1+0.5-1}$$

The steady flow energy balance gives

$$H_R = Q_{\text{out}} + H_P$$

where

$$\begin{aligned}
 H_R &= 1\bar{h}_{\text{C}_8\text{H}_{18}@298\text{ K}} + P_{\text{th}}a_{\text{th}}\bar{h}_{\text{O}_2@298\text{ K}} + (P_{\text{th}}a_{\text{th}} \times 3.76)\bar{h}_{\text{N}_2@298\text{ K}} \\
 &= (-208,459) + P_{\text{th}}a_{\text{th}}(0) + (P_{\text{th}}a_{\text{th}} \times 3.76)(0) = -208,459 \text{ kJ/kmol} \\
 H_P &= a\bar{h}_{\text{CO}_2@2000\text{ K}} + b\bar{h}_{\text{CO}@2000\text{ K}} + d\bar{h}_{\text{H}_2\text{O}@2000\text{ K}} + e\bar{h}_{\text{O}_2@2000\text{ K}} + f\bar{h}_{\text{N}_2@2000\text{ K}} \\
 &= a(-302,128) + b(-53,826) + d(-169,171) + e(59,193) + f(56,115)
 \end{aligned}$$

The enthalpies are obtained from EES. Solving all the equations simultaneously using EES, we obtain

$$\begin{aligned}
 P_{\text{th}} &= 1.024, \quad a_{\text{th}} = 12.5, \quad a = 7.935, \quad b = 0.06544, \quad d = 9, \quad e = 0.3289, \quad f = 48.11 \\
 \text{PercentTh} &= P_{\text{th}} \times 100 = 1.024 \times 100 = \mathbf{102.4\%} \\
 Q_{\text{out}} &= \mathbf{995,500 \text{ kJ/kmol C}_8\text{H}_{18}}
 \end{aligned}$$

The copy of entire EES solution including parametric studies is given next:

### Fundamentals of Engineering (FE) Exam Problems

**16-115** If the equilibrium constant for the reaction  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$  is  $K$ , the equilibrium constant for the reaction  $2\text{H}_2\text{O} \rightarrow 2\text{H}_2 + \text{O}_2$  at the same temperature is

- (a)  $1/K$                       (b)  $1/(2K)$                       (c)  $2K$                       (d)  $K^2$                       (e)  $1/K^2$

*Answer* (e)  $1/K^2$

**16-116** If the equilibrium constant for the reaction  $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$  is  $K$ , the equilibrium constant for the reaction  $\text{CO}_2 + 3\text{N}_2 \rightarrow \text{CO} + \frac{1}{2}\text{O}_2 + 3\text{N}_2$  at the same temperature is

- (a)  $1/K$                       (b)  $1/(K + 3)$                       (c)  $4K$                       (d)  $K$                       (e)  $1/K^2$

*Answer* (a)  $1/K$

**16-117** The equilibrium constant for the reaction  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$  at 1 atm and  $1500^\circ\text{C}$  is given to be  $K$ . Of the reactions given below, all at  $1500^\circ\text{C}$ , the reaction that has a different equilibrium constant is

- (a)  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$  at 5 atm,  
 (b)  $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$  at 1 atm,  
 (c)  $\text{H}_2 + \text{O}_2 \rightarrow \text{H}_2\text{O} + \frac{1}{2}\text{O}_2$  at 2 atm,  
 (d)  $\text{H}_2 + \frac{1}{2}\text{O}_2 + 3\text{N}_2 \rightarrow \text{H}_2\text{O} + 3\text{N}_2$  at 5 atm,  
 (e)  $\text{H}_2 + \frac{1}{2}\text{O}_2 + 3\text{N}_2 \rightarrow \text{H}_2\text{O} + 3\text{N}_2$  at 1 atm,

*Answer* (b)  $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$  at 1 atm,

**16-118** Of the reactions given below, the reaction whose equilibrium composition at a specified temperature is not affected by pressure is

- (a)  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$   
 (b)  $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$   
 (c)  $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$   
 (d)  $\text{N}_2 \rightarrow 2\text{N}$   
 (e) all of the above.

*Answer* (c)  $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$

**16-119** Of the reactions given below, the reaction whose number of moles of products increases by the addition of inert gases into the reaction chamber at constant pressure and temperature is

- (a)  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$
- (b)  $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$
- (c)  $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$
- (d)  $\text{N}_2 \rightarrow 2\text{N}$
- (e) none of the above.

*Answer* (d)  $\text{N}_2 \rightarrow 2\text{N}$

**16-120** Moist air is heated to a very high temperature. If the equilibrium composition consists of  $\text{H}_2\text{O}$ ,  $\text{O}_2$ ,  $\text{N}_2$ ,  $\text{OH}$ ,  $\text{H}_2$ , and  $\text{NO}$ , the number of equilibrium constant relations needed to determine the equilibrium composition of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

*Answer* (c) 3

**16-121** Propane  $\text{C}_3\text{H}_8$  is burned with air, and the combustion products consist of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{O}_2$ ,  $\text{N}_2$ ,  $\text{OH}$ ,  $\text{H}_2$ , and  $\text{NO}$ . The number of equilibrium constant relations needed to determine the equilibrium composition of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

*Answer* (d) 4

**16-122** Consider a gas mixture that consists of three components. The number of independent variables that need to be specified to fix the state of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

*Answer* (d) 4

**16-123** The value of Henry's constant for CO<sub>2</sub> gas dissolved in water at 290 K is 12.8 MPa. Consider water exposed to air at 100 kPa that contains 3 percent CO<sub>2</sub> by volume. Under phase equilibrium conditions, the mole fraction of CO<sub>2</sub> gas dissolved in water at 290 K is

- (a)  $2.3 \times 10^{-4}$       (b)  $3.0 \times 10^{-4}$       (c)  $0.80 \times 10^{-4}$       (d)  $2.2 \times 10^{-4}$       (e)  $5.6 \times 10^{-4}$

*Answer* (a)  $2.3 \times 10^{-4}$

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

## 16-125 ... 16-128 Design and Essay Problems

# Chapter 17

## COMPRESSIBLE FLOW

### Stagnation Properties

**17-1C** The temperature of the air will rise as it approaches the nozzle because of the stagnation process.

**17-2C** Stagnation enthalpy combines the ordinary enthalpy and the kinetic energy of a fluid, and offers convenience when analyzing high-speed flows. It differs from the ordinary enthalpy by the kinetic energy term.

**17-3C** Dynamic temperature is the temperature rise of a fluid during a stagnation process.

**17-4C** No. Because the velocities encountered in air-conditioning applications are very low, and thus the static and the stagnation temperatures are practically identical.

**17-5** The state of air and its velocity are specified. The stagnation temperature and stagnation pressure of air are to be determined.

**Assumptions** 1 The stagnation process is isentropic. 2 Air is an ideal gas.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The stagnation temperature of air is determined from

$$T_0 = T + \frac{V^2}{2c_p} = 245.9 \text{ K} + \frac{(470 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{355.8 \text{ K}}$$

Other stagnation properties at the specified state are determined by considering an isentropic process between the specified state and the stagnation state,

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (44 \text{ kPa}) \left( \frac{355.8 \text{ K}}{245.9 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{160.3 \text{ kPa}}$$

**Discussion** Note that the stagnation properties can be significantly different than thermodynamic properties.

**17-6** Air at 300 K is flowing in a duct. The temperature that a stationary probe inserted into the duct will read is to be determined for different air velocities.

**Assumptions** The stagnation process is isentropic.

**Properties** The specific heat of air at room temperature is  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The air which strikes the probe will be brought to a complete stop, and thus it will undergo a stagnation process. The thermometer will sense the temperature of this stagnated air, which is the stagnation temperature,  $T_0$ . It is determined from

$$T_0 = T + \frac{V^2}{2c_p}$$

$$(a) \quad T_0 = 300 \text{ K} + \frac{(1 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{300.0 \text{ K}}$$

$$(b) \quad T_0 = 300 \text{ K} + \frac{(10 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{300.1 \text{ K}}$$

$$(c) \quad T_0 = 300 \text{ K} + \frac{(100 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{305.0 \text{ K}}$$

$$(d) \quad T_0 = 300 \text{ K} + \frac{(1000 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{797.5 \text{ K}}$$

**Discussion** Note that the stagnation temperature is nearly identical to the thermodynamic temperature at low velocities, but the difference between the two is very significant at high velocities,

**17-7** The states of different substances and their velocities are specified. The stagnation temperature and stagnation pressures are to be determined.

**Assumptions** 1 The stagnation process is isentropic. 2 Helium and nitrogen are ideal gases.

**Analysis** (a) Helium can be treated as an ideal gas with  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.667$  (Table A-2a). Then the stagnation temperature and pressure of helium are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 50^\circ\text{C} + \frac{(240 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 55.5^\circ\text{C}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (0.25 \text{ MPa}) \left( \frac{328.7 \text{ K}}{323.2 \text{ K}} \right)^{1.667/(1.667-1)} = 0.261 \text{ MPa}$$

(b) Nitrogen can be treated as an ideal gas with  $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.400$ . Then the stagnation temperature and pressure of nitrogen are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 50^\circ\text{C} + \frac{(300 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 93.3^\circ\text{C}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (0.15 \text{ MPa}) \left( \frac{366.5 \text{ K}}{323.2 \text{ K}} \right)^{1.4/(1.4-1)} = 0.233 \text{ MPa}$$

(c) Steam can be treated as an ideal gas with  $c_p = 1.865 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.329$ . Then the stagnation temperature and pressure of steam are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 350^\circ\text{C} + \frac{(480 \text{ m/s})^2}{2 \times 1.865 \text{ kJ/kg}\cdot^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 411.8^\circ\text{C} = 685 \text{ K}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (0.1 \text{ MPa}) \left( \frac{685 \text{ K}}{623.2 \text{ K}} \right)^{1.329/(1.329-1)} = 0.147 \text{ MPa}$$

**Discussion** Note that the stagnation properties can be significantly different than thermodynamic properties.

**17-8** The inlet stagnation temperature and pressure and the exit stagnation pressure of air flowing through a compressor are specified. The power input to the compressor is to be determined.

**Assumptions** 1 The compressor is isentropic. 2 Air is an ideal gas.

**Properties** The properties of air at room temperature are  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The exit stagnation temperature of air  $T_{02}$  is determined from

$$T_{02} = T_{01} \left( \frac{P_{02}}{P_{01}} \right)^{(k-1)/k} = (300.2 \text{ K}) \left( \frac{900}{100} \right)^{(1.4-1)/1.4} = 562.4 \text{ K}$$

From the energy balance on the compressor,

$$\dot{W}_{\text{in}} = \dot{m}(h_{20} - h_{01})$$

or,

$$\dot{W}_{\text{in}} = \dot{m} c_p (T_{02} - T_{01}) = (0.02 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(562.4 - 300.2) \text{ K} = \mathbf{5.27 \text{ kW}}$$

**Discussion** Note that the stagnation properties can be used conveniently in the energy equation.

**17-9E** Steam flows through a device. The stagnation temperature and pressure of steam and its velocity are specified. The static pressure and temperature of the steam are to be determined.

**Assumptions** 1 The stagnation process is isentropic. 2 Steam is an ideal gas.

**Properties** Steam can be treated as an ideal gas with  $c_p = 0.445 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.329$  (Table A-2Ea).

**Analysis** The static temperature and pressure of steam are determined from

$$T = T_0 - \frac{V^2}{2c_p} = 700^\circ\text{F} - \frac{(900 \text{ ft/s})^2}{2 \times 0.445 \text{ Btu/lbm}\cdot^\circ\text{F}} \left( \frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = \mathbf{663.6^\circ\text{F}}$$

$$P = P_0 \left( \frac{T}{T_0} \right)^{k/(k-1)} = (120 \text{ psia}) \left( \frac{1123.6 \text{ R}}{1160 \text{ R}} \right)^{1.329/(1.329-1)} = \mathbf{105.5 \text{ psia}}$$

**Discussion** Note that the stagnation properties can be significantly different than thermodynamic properties.

**17-10** The inlet stagnation temperature and pressure and the exit stagnation pressure of products of combustion flowing through a gas turbine are specified. The power output of the turbine is to be determined.

**Assumptions** 1 The expansion process is isentropic. 2 Products of combustion are ideal gases.

**Properties** The properties of products of combustion are given to be  $c_p = 1.157 \text{ kJ/kg}\cdot\text{K}$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.33$ .

**Analysis** The exit stagnation temperature  $T_{02}$  is determined to be

$$T_{02} = T_{01} \left( \frac{P_{02}}{P_{01}} \right)^{(k-1)/k} = (1023.2 \text{ K}) \left( \frac{0.1}{1} \right)^{(1.33-1)/1.33} = 577.9 \text{ K}$$

Also,

$$c_p = k c_v = k(c_p - R) \longrightarrow c_p = \frac{kR}{k-1} = \frac{1.33(0.287 \text{ kJ/kg}\cdot\text{K})}{1.33-1} = 1.157 \text{ kJ/kg}\cdot\text{K}$$

From the energy balance on the turbine,

$$-w_{\text{out}} = (h_{20} - h_{01})$$

or,

$$w_{\text{out}} = c_p(T_{01} - T_{02}) = (1.157 \text{ kJ/kg}\cdot\text{K})(1023.2 - 577.9) \text{ K} = \mathbf{515.2 \text{ kJ/kg}}$$

**Discussion** Note that the stagnation properties can be used conveniently in the energy equation.

**17-11** Air flows through a device. The stagnation temperature and pressure of air and its velocity are specified. The static pressure and temperature of air are to be determined.

**Assumptions** 1 The stagnation process is isentropic. 2 Air is an ideal gas.

**Properties** The properties of air at an anticipated average temperature of 600 K are  $c_p = 1.051 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.376$  (Table A-2b).

**Analysis** The static temperature and pressure of air are determined from

$$T = T_0 - \frac{V^2}{2c_p} = 673.2 - \frac{(570 \text{ m/s})^2}{2 \times 1.051 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{518.6 \text{ K}}$$

and

$$P_2 = P_{02} \left( \frac{T_2}{T_{02}} \right)^{k/(k-1)} = (0.6 \text{ MPa}) \left( \frac{518.6 \text{ K}}{673.2 \text{ K}} \right)^{1.376/(1.376-1)} = \mathbf{0.23 \text{ MPa}}$$

**Discussion** Note that the stagnation properties can be significantly different than thermodynamic properties.

## Speed of sound and Mach Number

**17-12C** Sound is an infinitesimally small pressure wave. It is generated by a small disturbance in a medium. It travels by wave propagation. Sound waves cannot travel in a vacuum.

**17-13C** Yes, it is. Because the amplitude of an ordinary sound wave is very small, and it does not cause any significant change in temperature and pressure.

**17-14C** The sonic speed in a medium depends on the properties of the medium, and it changes as the properties of the medium change.

**17-15C** In warm (higher temperature) air since  $c = \sqrt{kRT}$

**17-16C** Helium, since  $c = \sqrt{kRT}$  and helium has the highest  $kR$  value. It is about 0.40 for air, 0.35 for argon and 3.46 for helium.

**17-17C** Air at specified conditions will behave like an ideal gas, and the speed of sound in an ideal gas depends on temperature only. Therefore, the speed of sound will be the same in both mediums.

**17-18C** In general, no. Because the Mach number also depends on the speed of sound in gas, which depends on the temperature of the gas. The Mach number will remain constant if the temperature is maintained constant.

**17-19** The Mach number of scramjet and the air temperature are given. The speed of the engine is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$ . Its specific heat ratio at room temperature is  $k = 1.4$  (Table A-2a).

**Analysis** The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(253 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 318.8 \text{ m/s}$$

and

$$V = cMa = (318.83 \text{ m/s})(7) \left( \frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right) = \mathbf{8035 \text{ km/h}}$$

**17-20E** The Mach number of scramjet and the air temperature are given. The speed of the engine is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of air is  $R = 0.06855 \text{ Btu/lbm} \cdot \text{R}$ . Its specific heat ratio at room temperature is  $k = 1.4$  (Table A-2Ea).

**Analysis** The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(460 \text{ R}) \left( \frac{25,037 \text{ ft}^2 / \text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1051.3 \text{ ft/s}$$

and

$$V = cMa = (1051.3 \text{ ft/s})(7) \left( \frac{1 \text{ mi/h}}{1.46667 \text{ ft/s}} \right) = \mathbf{5018 \text{ mi/h}}$$

**17-21** The speed of an airplane and the air temperature are given. It is to be determined if the speed of this airplane is subsonic or supersonic.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$ . Its specific heat ratio at room temperature is  $k = 1.4$  (Table A-2a).

**Analysis** The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(223 \text{ K}) \left( \frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right) \left( \frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right)} = 1077.6 \text{ km/h}$$

and

$$Ma = \frac{V}{c} = \frac{920 \text{ km/h}}{1077.6 \text{ km/h}} = \mathbf{0.854}$$

The speed of the airplane is subsonic since the Mach number is less than 1.

**17-22** The Mach number of an aircraft and the velocity of sound in air are to be determined at two specified temperatures.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Analysis** (a) At 300 K air can be treated as an ideal gas with  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a). Thus

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = \mathbf{347.2 \text{ m/s}}$$

and

$$\text{Ma} = \frac{V}{c} = \frac{280 \text{ m/s}}{347.2 \text{ m/s}} = \mathbf{0.81}$$

(b) At 1000 K,

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(1000 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = \mathbf{634 \text{ m/s}}$$

and

$$\text{Ma} = \frac{V}{c} = \frac{280 \text{ m/s}}{634 \text{ m/s}} = \mathbf{0.442}$$

**Discussion** Note that a constant Mach number does not necessarily indicate constant speed. The Mach number of a rocket, for example, will be increasing even when it ascends at constant speed. Also, the specific heat ratio  $k$  changes with temperature, and the accuracy of the result at 1000 K can be improved by using the  $k$  value at that temperature (it would give  $k = 1.336$ ,  $c = 619 \text{ m/s}$ , and  $\text{Ma} = 0.452$ ).

**17-23** Carbon dioxide flows through a nozzle. The inlet temperature and velocity and the exit temperature of CO<sub>2</sub> are specified. The Mach number is to be determined at the inlet and exit of the nozzle.

**Assumptions** 1 CO<sub>2</sub> is an ideal gas with constant specific heats at room temperature. 2 This is a steady-flow process.

**Properties** The gas constant of carbon dioxide is  $R = 0.1889$  kJ/kg·K. Its constant pressure specific heat and specific heat ratio at room temperature are  $c_p = 0.8439$  kJ/kg·K and  $k = 1.288$  (Table A-2a).

**Analysis** (a) At the inlet

$$c_1 = \sqrt{k_1 R T_1} = \sqrt{(1.288)(0.1889 \text{ kJ/kg} \cdot \text{K})(1200 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 540.4 \text{ m/s}$$

Thus,

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{50 \text{ m/s}}{540.4 \text{ m/s}} = \mathbf{0.0925}$$

(b) At the exit,

$$c_2 = \sqrt{k_2 R T_2} = \sqrt{(1.288)(0.1889 \text{ kJ/kg} \cdot \text{K})(400 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 312 \text{ m/s}$$

The nozzle exit velocity is determined from the steady-flow energy balance relation,

$$0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \rightarrow 0 = c_p (T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$0 = (0.8439 \text{ kJ/kg} \cdot \text{K})(1200 - 400 \text{ K}) + \frac{V_2^2 - (50 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \rightarrow V_2 = 1163 \text{ m/s}$$

Thus,

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1163 \text{ m/s}}{312 \text{ m/s}} = \mathbf{3.73}$$

**Discussion** The specific heats and their ratio  $k$  change with temperature, and the accuracy of the results can be improved by accounting for this variation. Using EES (or another property database):

$$\text{At } 1200 \text{ K: } c_p = 1.278 \text{ kJ/kg} \cdot \text{K}, k = 1.173 \rightarrow c_1 = 516 \text{ m/s}, V_1 = 50 \text{ m/s}, \text{Ma}_1 = 0.0969$$

$$\text{At } 400 \text{ K: } c_p = 0.9383 \text{ kJ/kg} \cdot \text{K}, k = 1.252 \rightarrow c_2 = 308 \text{ m/s}, V_2 = 1356 \text{ m/s}, \text{Ma}_2 = 4.41$$

Therefore, the constant specific heat assumption results in an error of **4.5%** at the inlet and **15.5%** at the exit in the Mach number, which are significant.

**17-24** Nitrogen flows through a heat exchanger. The inlet temperature, pressure, and velocity and the exit pressure and velocity are specified. The Mach number is to be determined at the inlet and exit of the heat exchanger.

**Assumptions** 1  $N_2$  is an ideal gas. 2 This is a steady-flow process. 3 The potential energy change is negligible.

**Properties** The gas constant of  $N_2$  is  $R = 0.2968 \text{ kJ/kg} \cdot \text{K}$ . Its constant pressure specific heat and specific heat ratio at room temperature are  $c_p = 1.040 \text{ kJ/kg} \cdot \text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** At the inlet, the speed of sound is

$$c_1 = \sqrt{k_1 R T_1} = \sqrt{(1.400)(0.2968 \text{ kJ/kg} \cdot \text{K})(283 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 342.9 \text{ m/s}$$

Thus,

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{100 \text{ m/s}}{342.9 \text{ m/s}} = \mathbf{0.292}$$

From the energy balance on the heat exchanger,

$$q_{\text{in}} = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$120 \text{ kJ/kg} = (1.040 \text{ kJ/kg} \cdot \text{K})(T_2 - 10^\circ\text{C}) + \frac{(200 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

It yields

$$T_2 = 111^\circ\text{C} = 384 \text{ K}$$

$$c_2 = \sqrt{k_2 R T_2} = \sqrt{(1.4)(0.2968 \text{ kJ/kg} \cdot \text{K})(384 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 399 \text{ m/s}$$

Thus,

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{200 \text{ m/s}}{399 \text{ m/s}} = \mathbf{0.501}$$

**Discussion** The specific heats and their ratio  $k$  change with temperature, and the accuracy of the results can be improved by accounting for this variation. Using EES (or another property database):

$$\text{At } 10^\circ\text{C} : c_p = 1.038 \text{ kJ/kg} \cdot \text{K}, k = 1.400 \rightarrow c_1 = 343 \text{ m/s}, V_1 = 100 \text{ m/s}, \text{Ma}_1 = 0.292$$

$$\text{At } 111^\circ\text{C} : c_p = 1.041 \text{ kJ/kg} \cdot \text{K}, k = 1.399 \rightarrow c_2 = 399 \text{ m/s}, V_2 = 200 \text{ m/s}, \text{Ma}_2 = 0.501$$

Therefore, the constant specific heat assumption results in no error at the inlet and at the exit in the Mach number.

**17-25** The speed of sound in refrigerant-134a at a specified state is to be determined.

**Assumptions** R-134a is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of R-134a is  $R = 0.08149 \text{ kJ/kg} \cdot \text{K}$ . Its specific heat ratio at room temperature is  $k = 1.108$ .

**Analysis** From the ideal-gas speed of sound relation,

$$c = \sqrt{kRT} = \sqrt{(1.108)(0.08149 \text{ kJ/kg} \cdot \text{K})(60 + 273 \text{ K}) \left( \frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{173 \text{ m/s}}$$

**Discussion** Note that the speed of sound is independent of pressure for ideal gases.

**17-26** The Mach number of a passenger plane for specified limiting operating conditions is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The gas constant of air is  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$ . Its specific heat ratio at room temperature is  $k = 1.4$  (Table A-2a).

**Analysis** From the speed of sound relation

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(-60 + 273 \text{ K}) \left( \frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 293 \text{ m/s}$$

Thus, the Mach number corresponding to the maximum cruising speed of the plane is

$$\text{Ma} = \frac{V_{\max}}{c} = \frac{(945 / 3.6) \text{ m/s}}{293 \text{ m/s}} = \mathbf{0.897}$$

**Discussion** Note that this is a subsonic flight since  $\text{Ma} < 1$ . Also, using a  $k$  value at  $-60^\circ\text{C}$  would give practically the same result.

**17-27E** Steam flows through a device at a specified state and velocity. The Mach number of steam is to be determined assuming ideal gas behavior.

**Assumptions** Steam is an ideal gas with constant specific heats.

**Properties** The gas constant of steam is  $R = 0.1102 \text{ Btu/lbm} \cdot \text{R}$ . Its specific heat ratio is given to be  $k = 1.3$ .

**Analysis** From the ideal-gas speed of sound relation,

$$c = \sqrt{kRT} = \sqrt{(1.3)(0.1102 \text{ Btu/lbm} \cdot \text{R})(1160 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 2040.8 \text{ ft/s}$$

Thus,

$$\text{Ma} = \frac{V}{c} = \frac{900 \text{ ft/s}}{2040 \text{ ft/s}} = \mathbf{0.441}$$

**Discussion** Using property data from steam tables and not assuming ideal gas behavior, it can be shown that the Mach number in steam at the specified state is 0.446, which is sufficiently close to the ideal-gas value of 0.441. Therefore, the ideal gas approximation is a reasonable one in this case.

**17-28E EES** Problem 17-27E is reconsidered. The variation of Mach number with temperature as the temperature changes between 350 and 700°F is to be investigated, and the results are to be plotted.

**Analysis** Using EES, this problem can be solved as follows:

```
T=Temperature+460
R=0.1102
V=900
k=1.3
c=SQRT(k*R*T*25037)
Ma=V/c
```

| Temperature,<br>$T, ^\circ\text{F}$ | Mach number<br>Ma |
|-------------------------------------|-------------------|
| 350                                 | 0.528             |
| 375                                 | 0.520             |
| 400                                 | 0.512             |
| 425                                 | 0.505             |
| 450                                 | 0.498             |
| 475                                 | 0.491             |
| 500                                 | 0.485             |
| 525                                 | 0.479             |
| 550                                 | 0.473             |
| 575                                 | 0.467             |
| 600                                 | 0.462             |
| 625                                 | 0.456             |
| 650                                 | 0.451             |
| 675                                 | 0.446             |
| 700                                 | 0.441             |

**Discussion** Note that for a specified flow speed, the Mach number decreases with increasing temperature, as expected.

**17-29** The expression for the speed of sound for an ideal gas is to be obtained using the isentropic process equation and the definition of the speed of sound.

**Analysis** The isentropic relation  $P\nu^k = A$  where  $A$  is a constant can also be expressed as

$$P = A \left( \frac{1}{\nu} \right)^k = A \rho^k$$

Substituting it into the relation for the speed of sound,

$$c^2 = \left( \frac{\partial P}{\partial \rho} \right)_s = \left( \frac{\partial (A \rho^k)}{\partial \rho} \right)_s = k A \rho^{k-1} = k (A \rho^k) / \rho = k (P / \rho) = k R T$$

since for an ideal gas  $P = \rho R T$  or  $R T = P / \rho$ . Therefore,

$$c = \sqrt{k R T}$$

which is the desired relation.

**17-30** The inlet state and the exit pressure of air are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The properties of air are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a). The specific heat ratio  $k$  varies with temperature, but in our case this change is very small and can be disregarded.

**Analysis** The final temperature of air is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (333.2 \text{ K}) \left( \frac{0.4 \text{ MPa}}{1.5 \text{ MPa}} \right)^{(1.4-1)/1.4} = 228.4 \text{ K}$$

Treating  $k$  as a constant, the ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{333.2}}{\sqrt{228.4}} = 1.21$$

**Discussion** Note that the speed of sound is proportional to the square root of thermodynamic temperature.

**17-31** The inlet state and the exit pressure of helium are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

**Assumptions** Helium is an ideal gas with constant specific heats at room temperature.

**Properties** The properties of helium are  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.667$  (Table A-2a).

**Analysis** The final temperature of helium is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (333.2 \text{ K}) \left( \frac{0.4}{1.5} \right)^{(1.667-1)/1.667} = 196.3 \text{ K}$$

The ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{333.2}}{\sqrt{196.3}} = \mathbf{1.30}$$

**Discussion** Note that the speed of sound is proportional to the square root of thermodynamic temperature.

**17-32E** The inlet state and the exit pressure of air are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The properties of air are  $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$  and  $k = 1.4$  (Table A-2Ea). The specific heat ratio  $k$  varies with temperature, but in our case this change is very small and can be disregarded.

**Analysis** The final temperature of air is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left( \frac{P_2}{P_1} \right)^{(k-1)/k} = (659.7 \text{ R}) \left( \frac{60}{170} \right)^{(1.4-1)/1.4} = 489.9 \text{ R}$$

Treating  $k$  as a constant, the ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{659.7}}{\sqrt{489.9}} = \mathbf{1.16}$$

**Discussion** Note that the speed of sound is proportional to the square root of thermodynamic temperature.

### One Dimensional Isentropic Flow

**17-33C** (a) The exit velocity remain constant at sonic speed, (b) the mass flow rate through the nozzle decreases because of the reduced flow area.

**17-34C** (a) The velocity will decrease, (b), (c), (d) the temperature, the pressure, and the density of the fluid will increase.

**17-35C** (a) The velocity will increase, (b), (c), (d) the temperature, the pressure, and the density of the fluid will decrease.

**17-36C** (a) The velocity will increase, (b), (c), (d) the temperature, the pressure, and the density of the fluid will decrease.

**17-37C** (a) The velocity will decrease, (b), (c), (d) the temperature, the pressure and the density of the fluid will increase.

**17-38C** They will be identical.

**17-39C** No, it is not possible.

**17-40** Air enters a converging-diverging nozzle at specified conditions. The lowest pressure that can be obtained at the throat of the nozzle is to be determined.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The specific heat ratio of air at room temperature is  $k = 1.4$  (Table A-2a).

**Analysis** The lowest pressure that can be obtained at the throat is the critical pressure  $P^*$ , which is determined from

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (1.2 \text{ MPa}) \left( \frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{0.634 \text{ MPa}}$$

**Discussion** This is the pressure that occurs at the throat when the flow past the throat is supersonic.

**17-41** Helium enters a converging-diverging nozzle at specified conditions. The lowest temperature and pressure that can be obtained at the throat of the nozzle are to be determined.

**Assumptions** 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of helium are  $k = 1.667$  and  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The lowest temperature and pressure that can be obtained at the throat are the critical temperature  $T^*$  and critical pressure  $P^*$ . First we determine the stagnation temperature  $T_0$  and stagnation pressure  $P_0$ ,

$$T_0 = T + \frac{V^2}{2c_p} = 800 \text{ K} + \frac{(100 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 801 \text{ K}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (0.7 \text{ MPa}) \left( \frac{801 \text{ K}}{800 \text{ K}} \right)^{1.667/(1.667-1)} = 0.702 \text{ MPa}$$

Thus,

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (801 \text{ K}) \left( \frac{2}{1.667+1} \right) = \mathbf{601 \text{ K}}$$

and

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (0.702 \text{ MPa}) \left( \frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = \mathbf{0.342 \text{ MPa}}$$

**Discussion** These are the temperature and pressure that will occur at the throat when the flow past the throat is supersonic.

**17-42** The critical temperature, pressure, and density of air and helium are to be determined at specified conditions.

**Assumptions** Air and Helium are ideal gases with constant specific heats at room temperature.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 1.4$ , and  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ . The properties of helium at room temperature are  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 1.667$ , and  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** (a) Before we calculate the critical temperature  $T^*$ , pressure  $P^*$ , and density  $\rho^*$ , we need to determine the stagnation temperature  $T_0$ , pressure  $P_0$ , and density  $\rho_0$ .

$$T_0 = 100^\circ\text{C} + \frac{V^2}{2c_p} = 100 + \frac{(250 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 131.1^\circ\text{C}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left( \frac{404.3 \text{ K}}{373.2 \text{ K}} \right)^{1.4/(1.4-1)} = 264.7 \text{ kPa}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{264.7 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(404.3 \text{ K})} = 2.281 \text{ kg/m}^3$$

Thus,

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (404.3 \text{ K}) \left( \frac{2}{1.4+1} \right) = 337 \text{ K}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (264.7 \text{ kPa}) \left( \frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = 140 \text{ kPa}$$

$$\rho^* = \rho_0 \left( \frac{2}{k+1} \right)^{1/(k-1)} = (2.281 \text{ kg/m}^3) \left( \frac{2}{1.4+1} \right)^{1/(1.4-1)} = 1.45 \text{ kg/m}^3$$

(b) For helium,

$$T_0 = T + \frac{V^2}{2c_p} = 40 + \frac{(300 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 48.7^\circ\text{C}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left( \frac{321.9 \text{ K}}{313.2 \text{ K}} \right)^{1.667/(1.667-1)} = 214.2 \text{ kPa}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{214.2 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(321.9 \text{ K})} = 0.320 \text{ kg/m}^3$$

Thus,

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (321.9 \text{ K}) \left( \frac{2}{1.667+1} \right) = 241 \text{ K}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (214.2 \text{ kPa}) \left( \frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 104.3 \text{ kPa}$$

$$\rho^* = \rho_0 \left( \frac{2}{k+1} \right)^{1/(k-1)} = (0.320 \text{ kg/m}^3) \left( \frac{2}{1.667+1} \right)^{1/(1.667-1)} = 0.208 \text{ kg/m}^3$$

**Discussion** These are the temperature, pressure, and density values that will occur at the throat when the flow past the throat is supersonic.

**17-43** Stationary carbon dioxide at a given state is accelerated isentropically to a specified Mach number. The temperature and pressure of the carbon dioxide after acceleration are to be determined.

**Assumptions** Carbon dioxide is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of the carbon dioxide at 400 K is  $k = 1.252$  (Table A-2b).

**Analysis** The inlet temperature and pressure in this case is equivalent to the stagnation temperature and pressure since the inlet velocity of the carbon dioxide said to be negligible. That is,  $T_0 = T_i = 400$  K and  $P_0 = P_i = 600$  kPa. Then,

$$T = T_0 \left( \frac{2}{2 + (k-1)M^2} \right) = (400 \text{ K}) \left( \frac{2}{2 + (1.252-1)(0.5)^2} \right) = \mathbf{387.8 \text{ K}}$$

and

$$P = P_0 \left( \frac{T}{T_0} \right)^{k/(k-1)} = (600 \text{ kPa}) \left( \frac{387.8 \text{ K}}{400 \text{ K}} \right)^{1.252/(1.252-1)} = \mathbf{514.3 \text{ kPa}}$$

**Discussion** Note that both the pressure and temperature drop as the gas is accelerated as part of the internal energy of the gas is converted to kinetic energy.

**17-44** Air flows through a duct. The state of the air and its Mach number are specified. The velocity and the stagnation pressure, temperature, and density of the air are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(373.2 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 387.2 \text{ m/s}$$

Thus,

$$V = \text{Ma} \times c = (0.8)(387.2 \text{ m/s}) = \mathbf{310 \text{ m/s}}$$

Also,

$$\rho = \frac{P}{RT} = \frac{200 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(373.2 \text{ K})} = 1.867 \text{ kg/m}^3$$

Then the stagnation properties are determined from

$$T_0 = T \left( 1 + \frac{(k-1)\text{Ma}^2}{2} \right) = (373.2 \text{ K}) \left( 1 + \frac{(1.4-1)(0.8)^2}{2} \right) = \mathbf{421 \text{ K}}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left( \frac{421.0 \text{ K}}{373.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{305 \text{ kPa}}$$

$$\rho_0 = \rho \left( \frac{T_0}{T} \right)^{1/(k-1)} = (1.867 \text{ kg/m}^3) \left( \frac{421.0 \text{ K}}{373.2 \text{ K}} \right)^{1/(1.4-1)} = \mathbf{2.52 \text{ kg/m}^3}$$

**Discussion** Note that both the pressure and temperature drop as the gas is accelerated as part of the internal energy of the gas is converted to kinetic energy.

**17-45 EES** Problem 17-44 is reconsidered. The effect of Mach number on the velocity and stagnation properties as the Ma is varied from 0.1 to 2 are to be investigated, and the results are to be plotted.

**Analysis** Using EES, the problem is solved as follows:

P=200  
 T=100+273.15  
 R=0.287  
 k=1.4  
 c=SQRT(k\*R\*T\*1000)  
 Ma=V/c  
 rho=P/(R\*T)

"Stagnation properties"

$T_0 = T \cdot (1 + (k-1) \cdot Ma^2 / 2)$   
 $P_0 = P \cdot (T_0 / T)^{k / (k-1)}$   
 $\rho_0 = \rho \cdot (T_0 / T)^{1 / (k-1)}$

| 1.8             | 697.0               | 615.0                             | 1149.2                               | 6.511                                                |
| 1.9             | 735.7               | 642.6                             | 1340.1                               | 7.267                                                |
| 2.0             | 774.4               | 671.7                             | 1564.9                               | 8.118                                                |

**Discussion** Note that as Mach number increases, so does the flow velocity and stagnation temperature, pressure, and density.

**17-46E** Air flows through a duct at a specified state and Mach number. The velocity and the stagnation pressure, temperature, and density of the air are to be determined.

**Assumptions** Air is an ideal gas with constant specific heats at room temperature.

**Properties** The properties of air are  $R = 0.06855 \text{ Btu/lbm} \cdot \text{R} = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  and  $k = 1.4$  (Table A-2Ea).

**Analysis** The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(671.7 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1270.4 \text{ ft/s}$$

Thus,

$$V = \text{Ma} \times c = (0.8)(1270.4 \text{ ft/s}) = \mathbf{1016 \text{ ft/s}}$$

Also,

$$\rho = \frac{P}{RT} = \frac{30 \text{ psia}}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(671.7 \text{ R})} = 0.1206 \text{ lbm/ft}^3$$

Then the stagnation properties are determined from

$$T_0 = T \left( 1 + \frac{(k-1)\text{Ma}^2}{2} \right) = (671.7 \text{ R}) \left( 1 + \frac{(1.4-1)(0.8)^2}{2} \right) = \mathbf{758 \text{ R}}$$

$$P_0 = P \left( \frac{T_0}{T} \right)^{k/(k-1)} = (30 \text{ psia}) \left( \frac{757.7 \text{ R}}{671.7 \text{ R}} \right)^{1.4/(1.4-1)} = \mathbf{45.7 \text{ psia}}$$

$$\rho_0 = \rho \left( \frac{T_0}{T} \right)^{1/(k-1)} = (0.1206 \text{ lbm/ft}^3) \left( \frac{757.7 \text{ R}}{671.7 \text{ R}} \right)^{1/(1.4-1)} = \mathbf{0.163 \text{ lbm/ft}^3}$$

**Discussion** Note that the temperature, pressure, and density of a gas increases during a stagnation process.

**17-47** An aircraft is designed to cruise at a given Mach number, elevation, and the atmospheric temperature. The stagnation temperature on the leading edge of the wing is to be determined.

**Assumptions** Air is an ideal gas.

**Properties** The properties of air are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(236.15 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 308.0 \text{ m/s}$$

Thus,

$$V = \text{Ma} \times c = (1.2)(308.0 \text{ m/s}) = 369.6 \text{ m/s}$$

Then,

$$T_0 = T + \frac{V^2}{2c_p} = 236.15 + \frac{(369.6 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}}\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) = \mathbf{304.1 \text{ K}}$$

**Discussion** Note that the temperature of a gas increases during a stagnation process as the kinetic energy is converted to enthalpy.

**Isentropic Flow Through Nozzles**

**17-48C** (a) The exit velocity will reach the sonic speed, (b) the exit pressure will equal the critical pressure, and (c) the mass flow rate will reach the maximum value.

**17-49C** (a) None, (b) None, and (c) None.

**17-50C** They will be the same.

**17-51C** Maximum flow rate through a nozzle is achieved when  $Ma = 1$  at the exit of a subsonic nozzle. For all other  $Ma$  values the mass flow rate decreases. Therefore, the mass flow rate would decrease if hypersonic velocities were achieved at the throat of a converging nozzle.

**17-52C**  $Ma^*$  is the local velocity non-dimensionalized with respect to the sonic speed at the throat, whereas  $Ma$  is the local velocity non-dimensionalized with respect to the local sonic speed.

**17-53C** The fluid would accelerate even further instead of decelerating.

**17-54C** The fluid would decelerate instead of accelerating.

**17-55C** (a) The velocity will decrease, (b) the pressure will increase, and (c) the mass flow rate will remain the same.

**17-56C** No. If the velocity at the throat is subsonic, the diverging section will act like a diffuser and decelerate the flow.

**17-57** It is to be explained why the maximum flow rate per unit area for a given ideal gas depends only on  $P_0 / \sqrt{T_0}$ . Also for an ideal gas, a relation is to be obtained for the constant  $a$  in  $\dot{m}_{\max} / A^* = a(P_0 / \sqrt{T_0})$ .

**Properties** The properties of the ideal gas considered are  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The maximum flow rate is given by

$$\dot{m}_{\max} = A^* P_0 \sqrt{k / RT_0} \left( \frac{2}{k+1} \right)^{(k+1)/2(k-1)}$$

or

$$\dot{m}_{\max} / A^* = (P_0 / \sqrt{T_0}) \sqrt{k / R} \left( \frac{2}{k+1} \right)^{(k+1)/2(k-1)}$$

For a given gas,  $k$  and  $R$  are fixed, and thus the mass flow rate depends on the parameter  $P_0 / \sqrt{T_0}$ .

$\dot{m}_{\max} / A^*$  can be expressed as  $\dot{m}_{\max} / A^* = a(P_0 / \sqrt{T_0})$  where

$$a = \sqrt{k / R} \left( \frac{2}{k+1} \right)^{(k+1)/2(k-1)} = \sqrt{\frac{1.4}{(0.287 \text{ kJ/kg}\cdot\text{K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}} \left( \frac{2}{1.4+1} \right)^{2.4/0.8} = 0.0404 (\text{m/s})\sqrt{\text{K}}$$

**Discussion** Note that when sonic conditions exist at a throat of known cross-sectional area, the mass flow rate is fixed by the stagnation conditions.

**17-58** For an ideal gas, an expression is to be obtained for the ratio of the speed of sound where  $\text{Ma} = 1$  to the speed of sound based on the stagnation temperature,  $c^*/c_0$ .

**Analysis** For an ideal gas the speed of sound is expressed as  $c = \sqrt{kRT}$ . Thus,

$$\frac{c^*}{c_0} = \frac{\sqrt{kRT^*}}{\sqrt{kRT_0}} = \left( \frac{T^*}{T_0} \right)^{1/2} = \left( \frac{2}{k+1} \right)^{1/2}$$

**Discussion** Note that a speed of sound changes the flow as the temperature changes.

**17-59** For subsonic flow at the inlet, the variation of pressure, velocity, and Mach number along the length of the nozzle are to be sketched for an ideal gas under specified conditions.

**Analysis** Using EES and CO<sub>2</sub> as the gas, we calculate and plot flow area  $A$ , velocity  $V$ , and Mach number  $Ma$  as the pressure drops from a stagnation value of 1400 kPa to 200 kPa. Note that the curve for  $A$  represents the shape of the nozzle, with horizontal axis serving as the centerline.

**Discussion** Note that this problem is identical to the preceding one, except the flow direction is reversed.

**17-61** Air enters a nozzle at specified temperature, pressure, and velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of  $Ma = 1$  at the exit.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of air are  $k = 1.4$  and  $c_p = 1.005$  kJ/kg·K (Table A-2a).

**Analysis** The properties of the fluid at the location where  $Ma = 1$  are the critical properties, denoted by superscript \*. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 350 \text{ K} + \frac{(150 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg} \cdot \text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 361.2 \text{ K}$$

and

$$P_0 = P_i \left( \frac{T_0}{T_i} \right)^{k/(k-1)} = (0.2 \text{ MPa}) \left( \frac{361.2 \text{ K}}{350 \text{ K}} \right)^{1.4/(1.4-1)} = 0.223 \text{ MPa}$$

From Table A-32 (or from Eqs. 17-18 and 17-19) at  $Ma = 1$ , we read  $T/T_0 = 0.8333$ ,  $P/P_0 = 0.5283$ . Thus,

$$T = 0.8333 T_0 = 0.8333(361.2 \text{ K}) = \mathbf{301 \text{ K}}$$

and

$$P = 0.5283 P_0 = 0.5283(0.223 \text{ MPa}) = \mathbf{0.118 \text{ MPa}}$$

Also,

$$c_i = \sqrt{kRT_i} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(350 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 375 \text{ m/s}$$

and

$$Ma_i = \frac{V_i}{c_i} = \frac{150 \text{ m/s}}{375 \text{ m/s}} = 0.40$$

From Table A-32 at this Mach number we read  $A_i/A^* = 1.5901$ . Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{1.5901} = \mathbf{0.629}$$

**Discussion** We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

**17-62** Air enters a nozzle at specified temperature and pressure with low velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of  $Ma = 1$  at the exit.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** The properties of the fluid at the location where  $Ma = 1$  are the critical properties, denoted by superscript \*. The stagnation temperature and pressure in this case are identical to the inlet temperature and pressure since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i = 350 \text{ K}$$

$$P_0 = P_i = 0.2 \text{ MPa}$$

From Table A-32 (or from Eqs. 17-18 and 17-19) at  $Ma = 1$ , we read  $T/T_0 = 0.8333$ ,  $P/P_0 = 0.5283$ . Thus,

$$T = 0.8333T_0 = 0.8333(350 \text{ K}) = \mathbf{292 \text{ K}}$$

and

$$P = 0.5283P_0 = 0.5283(0.2 \text{ MPa}) = \mathbf{0.106 \text{ MPa}}$$

The Mach number at the nozzle inlet is  $Ma = 0$  since  $V_i \approx 0$ . From Table A-32 at this Mach number we read  $A_i/A^* = \infty$ . Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{\infty} = \mathbf{0}$$

**Discussion** We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

**17-63E** Air enters a nozzle at specified temperature, pressure, and velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of  $Ma = 1$  at the exit.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of air are  $k = 1.4$  and  $c_p = 0.240$  Btu/lbm·R (Table A-2Ea).

**Analysis** The properties of the fluid at the location where  $Ma = 1$  are the critical properties, denoted by superscript \*. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T + \frac{V_i^2}{2c_p} = 630 \text{ R} + \frac{(450 \text{ ft/s})^2}{2 \times 0.240 \text{ Btu/lbm} \cdot \text{R}} \left( \frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 646.9 \text{ R}$$

and

$$P_0 = P_i \left( \frac{T_0}{T_i} \right)^{k/(k-1)} = (30 \text{ psia}) \left( \frac{646.9 \text{ K}}{630 \text{ K}} \right)^{1.4/(1.4-1)} = 32.9 \text{ psia}$$

From Table A-32 (or from Eqs. 17-18 and 17-19) at  $Ma = 1$ , we read  $T/T_0 = 0.8333$ ,  $P/P_0 = 0.5283$ . Thus,

$$T = 0.8333T_0 = 0.8333(646.9 \text{ R}) = \mathbf{539 \text{ R}}$$

and

$$P = 0.5283P_0 = 0.5283(32.9 \text{ psia}) = \mathbf{17.4 \text{ psia}}$$

Also,

$$c_i = \sqrt{kRT_i} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(630 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1230 \text{ ft/s}$$

and

$$Ma_i = \frac{V_i}{c_i} = \frac{450 \text{ ft/s}}{1230 \text{ ft/s}} = 0.3657$$

From Table A-32 at this Mach number we read  $A_i/A^* = 1.7426$ . Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{1.7426} = \mathbf{0.574}$$

**Discussion** We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

**17-64** Air enters a converging-diverging nozzle at a specified pressure. The back pressure that will result in a specified exit Mach number is to be determined.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** The stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. It remains constant throughout the nozzle since the flow is isentropic,

$$P_0 = P_i = 0.5 \text{ MPa}$$

From Table A-32 at  $\text{Ma}_e = 1.8$ , we read  $P_e/P_0 = 0.1740$ .

Thus,

$$P = 0.1740P_0 = 0.1740(0.5 \text{ MPa}) = \mathbf{0.087 \text{ MPa}}$$

**Discussion** We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

**17-65** Nitrogen enters a converging-diverging nozzle at a given pressure. The critical velocity, pressure, temperature, and density in the nozzle are to be determined.

**Assumptions** 1 Nitrogen is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of nitrogen are  $k = 1.4$  and  $R = 0.2968 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle,

$$P_0 = P_i = 700 \text{ kPa}$$

$$T_0 = T_i = 450 \text{ K}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{700 \text{ kPa}}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(450 \text{ K})} = 5.241 \text{ kg/m}^3$$

Critical properties are those at a location where the Mach number is  $\text{Ma} = 1$ . From Table A-32 at  $\text{Ma} = 1$ , we read  $T/T_0 = 0.8333$ ,  $P/P_0 = 0.5283$ , and  $\rho/\rho_0 = 0.6339$ . Then the critical properties become

$$T^* = 0.8333T_0 = 0.8333(450 \text{ K}) = \mathbf{375 \text{ K}}$$

$$P^* = 0.52828P_0 = 0.5283(700 \text{ kPa}) = \mathbf{370 \text{ MPa}}$$

$$\rho^* = 0.63394\rho_0 = 0.6339(5.241 \text{ kg/m}^3) = \mathbf{3.32 \text{ kg/m}^3}$$

Also,

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.4)(0.2968 \text{ kJ/kg} \cdot \text{K})(375.0 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{395 \text{ m/s}}$$

**Discussion** We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

**17-66** An ideal gas is flowing through a nozzle. The flow area at a location where  $Ma = 2.4$  is specified. The flow area where  $Ma = 1.2$  is to be determined.

**Assumptions** Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The specific heat ratio is given to be  $k = 1.4$ .

**Analysis** The flow is assumed to be isentropic, and thus the stagnation and critical properties remain constant throughout the nozzle. The flow area at a location where  $Ma_2 = 1.2$  is determined using  $A/A^*$  data from Table A-32 to be

$$Ma_1 = 2.4 : \frac{A_1}{A^*} = 2.4031 \longrightarrow A^* = \frac{A_1}{2.4031} = \frac{25 \text{ cm}^2}{2.4031} = 10.40 \text{ cm}^2$$

$$Ma_2 = 1.2 : \frac{A_2}{A^*} = 1.0304 \longrightarrow A_2 = (1.0304)A^* = (1.0304)(10.40 \text{ cm}^2) = \mathbf{10.7 \text{ cm}^2}$$

**Discussion** We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

**17-67** An ideal gas is flowing through a nozzle. The flow area at a location where  $Ma = 2.4$  is specified. The flow area where  $Ma = 1.2$  is to be determined.

**Assumptions** Flow through the nozzle is steady, one-dimensional, and isentropic.

**Analysis** The flow is assumed to be isentropic, and thus the stagnation and critical properties remain constant throughout the nozzle. The flow area at a location where  $Ma_2 = 1.2$  is determined using the  $A/A^*$  relation,

$$\frac{A}{A^*} = \frac{1}{Ma} \left\{ \left( \frac{2}{k+1} \right) \left( 1 + \frac{k-1}{2} Ma^2 \right) \right\}^{(k+1)/2(k-1)}$$

For  $k = 1.33$  and  $Ma_1 = 2.4$ :

$$\frac{A_1}{A^*} = \frac{1}{2.4} \left\{ \left( \frac{2}{1.33+1} \right) \left( 1 + \frac{1.33-1}{2} 2.4^2 \right) \right\}^{2.33/2 \times 0.33} = 2.570$$

and,

$$A^* = \frac{A_1}{2.570} = \frac{25 \text{ cm}^2}{2.570} = 9.729 \text{ cm}^2$$

For  $k = 1.33$  and  $Ma_2 = 1.2$ :

$$\frac{A_2}{A^*} = \frac{1}{1.2} \left\{ \left( \frac{2}{1.33+1} \right) \left( 1 + \frac{1.33-1}{2} 1.2^2 \right) \right\}^{2.33/2 \times 0.33} = 1.0316$$

and

$$A_2 = (1.0316)A^* = (1.0316)(9.729 \text{ cm}^2) = \mathbf{10.0 \text{ cm}^2}$$

**Discussion** Note that the compressible flow functions in Table A-32 are prepared for  $k = 1.4$ , and thus they cannot be used to solve this problem.

**17-68 [Also solved by EES on enclosed CD]** Air enters a converging nozzle at a specified temperature and pressure with low velocity. The exit pressure, the exit velocity, and the mass flow rate versus the back pressure are to be calculated and plotted.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of air are  $k = 1.4$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$P_0 = P_i = 900 \text{ kPa}$$

$$T_0 = T_i = 400 \text{ K}$$

The critical pressure is determined to be

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (900 \text{ kPa}) \left( \frac{2}{1.4+1} \right)^{1.4/0.4} = 475.5 \text{ kPa}$$

Then the pressure at the exit plane (throat) will be

$$P_e = P_b \quad \text{for} \quad P_b \geq 475.5 \text{ kPa}$$

$$P_e = P^* = 475.5 \text{ kPa} \quad \text{for} \quad P_b < 475.5 \text{ kPa} \quad (\text{choked flow})$$

Thus the back pressure will not affect the flow when  $100 < P_b < 475.5 \text{ kPa}$ . For a specified exit pressure  $P_e$ , the temperature, the velocity and the mass flow rate can be determined from

$$\text{Temperature} \quad T_e = T_0 \left( \frac{P_e}{P_0} \right)^{(k-1)/k} = (400 \text{ K}) \left( \frac{P_e}{900} \right)^{0.4/1.4}$$

$$\text{Velocity } V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.005 \text{ kJ/kg}\cdot\text{K})(400 - T_e) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.001 \text{ m}^2)$$

The results of the calculations can be tabulated as

| $P_b, \text{ kPa}$ | $P_e, \text{ kPa}$ | $T_e, \text{ K}$ | $V_e, \text{ m/s}$ | $\rho_e, \text{ kg/m}^3$ | $\dot{m}, \text{ kg/s}$ |

**17-69 EES** Problem 17-68 is reconsidered. Using EES (or other) software, The problem is to be solved for the inlet conditions of 1 MPa and 1000 K.

**Analysis** Using EES, the problem is solved as follows:

```

Procedure ExitPress(P_back,P_crit : P_exit, Condition$)
If (P_back>=P_crit) then
    P_exit:=P_back          "Unchoked Flow Condition"
    Condition$='unchoked'
else
    P_exit:=P_crit          "Choked Flow Condition"
    Condition$='choked'
Endif
End

**17-70E** Air enters a converging-diverging nozzle at a specified temperature and pressure with low velocity. The pressure, temperature, velocity, and mass flow rate are to be calculated in the specified test section.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of air are  $k = 1.4$  and  $R = 0.06855 \text{ Btu/lbm}\cdot\text{R} = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$  (Table A-2Ea).

**Analysis** The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$P_0 = P_i = 150 \text{ psia}$$

$$T_0 = T_i = 100^\circ\text{F} = 560 \text{ R}$$

Then,

$$T_e = T_0 \left( \frac{2}{2 + (k-1)\text{Ma}^2} \right) = (560 \text{ R}) \left( \frac{2}{2 + (1.4-1)2^2} \right) = 311 \text{ R}$$

and

$$P_e = P_0 \left( \frac{T}{T_0} \right)^{k/(k-1)} = (150 \text{ psia}) \left( \frac{311}{560} \right)^{1.4/0.4} = 19.1 \text{ psia}$$

Also,

$$\rho_e = \frac{P_e}{RT_e} = \frac{19.1 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(311 \text{ R})} = 0.166 \text{ lbm/ft}^3$$

The nozzle exit velocity can be determined from  $V_e = \text{Ma}_e c_e$ , where  $c_e$  is the speed of sound at the exit conditions,

$$V_e = \text{Ma}_e c_e = \text{Ma}_e \sqrt{kRT_e} = (2) \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(311 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1729 \text{ ft/s}$$

Finally,

$$\dot{m} = \rho_e A_e V_e = (0.166 \text{ lbm/ft}^3)(5 \text{ ft}^2)(1729 \text{ ft/s}) = 1435 \text{ lbm/s}$$

**Discussion** Air must be very dry in this application because the exit temperature of air is extremely low, and any moisture in the air will turn to ice particles.

## Shock Waves and Expansion Waves

**17-71C** No, because the flow must be supersonic before a shock wave can occur. The flow in the converging section of a nozzle is always subsonic.

**17-72C** The Fanno line represents the states which satisfy the conservation of mass and energy equations. The Rayleigh line represents the states which satisfy the conservation of mass and momentum equations. The intersections points of these lines represents the states which satisfy the conservation of mass, energy, and momentum equations.

**17-73C** No, the second law of thermodynamics requires the flow after the shock to be subsonic..

**17-74C** (a) decreases, (b) increases, (c) remains the same, (d) increases, and (e) decreases.

**17-75C** Oblique shocks occur when a gas flowing at supersonic speeds strikes a flat or inclined surface. Normal shock waves are perpendicular to flow whereas inclined shock waves, as the name implies, are typically inclined relative to the flow direction. Also, normal shocks form a straight line whereas oblique shocks can be straight or curved, depending on the surface geometry.

**17-76C** Yes, the upstream flow have to be supersonic for an oblique shock to occur. No, the flow downstream of an oblique shock can be subsonic, sonic, and even supersonic.

**17-77C** Yes. Conversely, normal shocks can be thought of as special oblique shocks in which the shock angle is  $\beta = \pi/2$ , or  $90^\circ$ .

**17-78C** When the wedge half-angle  $\delta$  is greater than the maximum deflection angle  $\theta_{\max}$ , the shock becomes curved and detaches from the nose of the wedge, forming what is called a *detached oblique shock* or a *bow wave*. The numerical value of the shock angle at the nose is  $\beta = 90^\circ$ .

**17-79C** When supersonic flow impinges on a blunt body like the rounded nose of an aircraft, the wedge half-angle  $\delta$  at the nose is  $90^\circ$ , and an attached oblique shock cannot exist, regardless of Mach number. Therefore, a detached oblique shock must occur in front of *all* such blunt-nosed bodies, whether two-dimensional, axisymmetric, or fully three-dimensional.

**17-80C** Isentropic relations of ideal gases are *not* applicable for flows across (a) normal shock waves and (b) oblique shock waves, but they *are* applicable for flows across (c) Prandtl-Meyer expansion waves.

**17-81** For an ideal gas flowing through a normal shock, a relation for  $V_2/V_1$  in terms of  $k$ ,  $Ma_1$ , and  $Ma_2$  is to be developed.

**Analysis** The conservation of mass relation across the shock is  $\rho_1 V_1 = \rho_2 V_2$  and it can be expressed as

$$\frac{V_2}{V_1} = \frac{\rho_1}{\rho_2} = \frac{P_1 / RT_1}{P_2 / RT_2} = \left( \frac{P_1}{P_2} \right) \left( \frac{T_2}{T_1} \right)$$

From Eqs. 17-35 and 17-38,

$$\frac{V_2}{V_1} = \left( \frac{1 + kMa_2^2}{1 + kMa_1^2} \right) \left( \frac{1 + Ma_1^2(k-1)/2}{1 + Ma_2^2(k-1)/2} \right)$$

**Discussion** This is an important relation as it enables us to determine the velocity ratio across a normal shock when the Mach numbers before and after the shock are known.

**17-82** Air flowing through a converging-diverging nozzle experiences a normal shock at the exit. The effect of the shock wave on various properties is to be determined.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs. 3 The shock wave occurs at the exit plane.

**Properties** The properties of air are  $k = 1.4$  and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Then,

$$P_{01} = P_i = 1.5 \text{ MPa}$$

$$T_{01} = T_i = 350 \text{ K}$$

Then,

$$T_1 = T_{01} \left( \frac{2}{2 + (k-1)\text{Ma}_1^2} \right) = (350 \text{ K}) \left( \frac{2}{2 + (1.4-1)2^2} \right) = 194.4 \text{ K}$$

and

$$P_1 = P_{01} \left( \frac{T_1}{T_0} \right)^{k/(k-1)} = (1.5 \text{ MPa}) \left( \frac{194.4}{300} \right)^{1.4/0.4} = 0.1917 \text{ MPa}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For  $\text{Ma}_1 = 2.0$  we read

$$\text{Ma}_2 = \mathbf{0.5774}, \quad \frac{P_{02}}{P_{01}} = 0.7209, \quad \frac{P_2}{P_1} = 4.5000, \quad \text{and} \quad \frac{T_2}{T_1} = 1.6875$$

Then the stagnation pressure  $P_{02}$ , static pressure  $P_2$ , and static temperature  $T_2$ , are determined to be

$$P_{02} = 0.7209P_{01} = (0.7209)(1.5 \text{ MPa}) = \mathbf{1.081 \text{ MPa}}$$

$$P_2 = 4.5000P_1 = (4.5000)(0.1917 \text{ MPa}) = \mathbf{0.863 \text{ MPa}}$$

$$T_2 = 1.6875T_1 = (1.6875)(194.4 \text{ K}) = \mathbf{328.1 \text{ K}}$$

The air velocity after the shock can be determined from  $V_2 = \text{Ma}_2 c_2$ , where  $c_2$  is the velocity of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.5774) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(328.1 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{209.6 \text{ m/s}}$$

**Discussion** We can also solve this problem using the relations for normal shock functions. The results would be identical.

**17-83** Air enters a converging-diverging nozzle at a specified state. The required back pressure that produces a normal shock at the exit plane is to be determined for the specified nozzle geometry.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs. 3 The shock wave occurs at the exit plane.

**Analysis** The inlet stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. Since the flow before the shock to be isentropic,

$$P_{01} = P_i = 2 \text{ MPa}$$

It is specified that  $A/A^* = 3.5$ . From Table A-32, Mach number and the pressure ratio which corresponds to this area ratio are the  $Ma_1 = 2.80$  and  $P_1/P_{01} = 0.0368$ . The pressure ratio across the shock for this  $Ma_1$  value is, from Table A-33,  $P_2/P_1 = 8.98$ . Thus the back pressure, which is equal to the static pressure at the nozzle exit, must be

$$P_2 = 8.98P_1 = 8.98 \times 0.0368P_{01} = 8.98 \times 0.0368 \times (2 \text{ MPa}) = \mathbf{0.661 \text{ MPa}}$$

**Discussion** We can also solve this problem using the relations for compressible flow and normal shock functions. The results would be identical.

**17-84** Air enters a converging-diverging nozzle at a specified state. The required back pressure that produces a normal shock at the exit plane is to be determined for the specified nozzle geometry.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Analysis** The inlet stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. Since the flow before the shock to be isentropic,

$$P_{01} = P_i = 2 \text{ MPa}$$

It is specified that  $A/A^* = 2$ . From Table A-32, the Mach number and the pressure ratio which corresponds to this area ratio are the  $Ma_1 = 2.20$  and  $P_1/P_{01} = 0.0935$ . The pressure ratio across the shock for this  $Ma_1$  value is, from Table A-33,  $P_2/P_1 = 5.48$ . Thus the back pressure, which is equal to the static pressure at the nozzle exit, must be

$$P_2 = 5.48P_1 = 5.48 \times 0.0935P_{01} = 5.48 \times 0.0935 \times (2 \text{ MPa}) = \mathbf{1.02 \text{ MPa}}$$

**Discussion** We can also solve this problem using the relations for compressible flow and normal shock functions. The results would be identical.

**17-85** Air flowing through a nozzle experiences a normal shock. The effect of the shock wave on various properties is to be determined. Analysis is to be repeated for helium under the same conditions.

**Assumptions** 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Properties** The properties of air are  $k = 1.4$  and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and the properties of helium are  $k = 1.667$  and  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The air properties upstream the shock are

$$\text{Ma}_1 = 2.5, P_1 = 61.64 \text{ kPa}, \text{ and } T_1 = 262.15 \text{ K}$$

Fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions in Table A-33. For  $\text{Ma}_1 = 2.5$ ,

$$\text{Ma}_2 = \mathbf{0.513}, \frac{P_{02}}{P_1} = 8.5262, \frac{P_2}{P_1} = 7.125, \text{ and } \frac{T_2}{T_1} = 2.1375$$

Then the stagnation pressure  $P_{02}$ , static pressure  $P_2$ , and static temperature  $T_2$ , are determined to be

$$P_{02} = 8.5261P_1 = (8.5261)(61.64 \text{ kPa}) = \mathbf{526 \text{ kPa}}$$

$$P_2 = 7.125P_1 = (7.125)(61.64 \text{ kPa}) = \mathbf{439 \text{ kPa}}$$

$$T_2 = 2.1375T_1 = (2.1375)(262.15 \text{ K}) = \mathbf{560 \text{ K}}$$

The air velocity after the shock can be determined from  $V_2 = \text{Ma}_2 c_2$ , where  $c_2$  is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.513) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(560.3 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{243 \text{ m/s}}$$

We now repeat the analysis for helium. This time we cannot use the tabulated values in Table A-33 since  $k$  is not 1.4. Therefore, we have to calculate the desired quantities using the analytical relations,

$$\text{Ma}_2 = \left( \frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k/(k-1) - 1} \right)^{1/2} = \left( \frac{2.5^2 + 2/(1.667-1)}{2 \times 2.5^2 \times 1.667/(1.667-1) - 1} \right)^{1/2} = \mathbf{0.553}$$

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} = \frac{1 + 1.667 \times 2.5^2}{1 + 1.667 \times 0.553^2} = 7.5632$$

$$\frac{T_2}{T_1} = \frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2} = \frac{1 + 2.5^2(1.667-1)/2}{1 + 0.553^2(1.667-1)/2} = 2.7989$$

$$\begin{aligned} \frac{P_{02}}{P_1} &= \left( \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right) \left( 1 + (k-1)\text{Ma}_2^2/2 \right)^{k/(k-1)} \\ &= \left( \frac{1 + 1.667 \times 2.5^2}{1 + 1.667 \times 0.553^2} \right) \left( 1 + (1.667-1) \times 0.553^2/2 \right)^{1.667/0.667} = 9.641 \end{aligned}$$

Thus,  $P_{02} = 11.546P_1 = (9.641)(61.64 \text{ kPa}) = \mathbf{594 \text{ kPa}}$

$$P_2 = 7.5632P_1 = (7.5632)(61.64 \text{ kPa}) = \mathbf{466 \text{ kPa}}$$

$$T_2 = 2.7989T_1 = (2.7989)(262.15 \text{ K}) = \mathbf{734 \text{ K}}$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.553) \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(733.7 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{881 \text{ m/s}}$$

**17-86** Air flowing through a nozzle experiences a normal shock. The entropy change of air across the normal shock wave is to be determined.

**Assumptions** 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Properties** The properties of air are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and the properties of helium are  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$  and  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (1.005 \text{ kJ/kg}\cdot\text{K}) \ln(2.1375) - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(7.125) = \mathbf{0.200 \text{ kJ/kg}\cdot\text{K}}$$

For helium, the entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (5.1926 \text{ kJ/kg}\cdot\text{K}) \ln(2.7989) - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln(7.5632) = \mathbf{1.14 \text{ kJ/kg}\cdot\text{K}}$$

**Discussion** Note that shock wave is a highly dissipative process, and the entropy generation is large during shock waves.

**17-87E [Also solved by EES on enclosed CD]** Air flowing through a nozzle experiences a normal shock. Effect of the shock wave on various properties is to be determined. Analysis is to be repeated for helium.

**Assumptions** 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Properties** The properties of air are  $k = 1.4$  and  $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$ , and the properties of helium are  $k = 1.667$  and  $R = 0.4961 \text{ Btu/lbm}\cdot\text{R}$ .

**Analysis** The air properties upstream the shock are

$$\text{Ma}_1 = 2.5, P_1 = 10 \text{ psia}, \text{ and } T_1 = 440.5 \text{ R}$$

Fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For  $\text{Ma}_1 = 2.5$ ,

$$\text{Ma}_2 = \mathbf{0.513}, \frac{P_{02}}{P_1} = 8.5262, \frac{P_2}{P_1} = 7.125, \text{ and } \frac{T_2}{T_1} = 2.1375$$

Then the stagnation pressure  $P_{02}$ , static pressure  $P_2$ , and static temperature  $T_2$ , are determined to be

$$P_{02} = 8.5262P_1 = (8.5262)(10 \text{ psia}) = \mathbf{85.3 \text{ psia}}$$

$$P_2 = 7.125P_1 = (7.125)(10 \text{ psia}) = \mathbf{71.3 \text{ psia}}$$

$$T_2 = 2.1375T_1 = (2.1375)(440.5 \text{ R}) = \mathbf{942 \text{ R}}$$

The air velocity after the shock can be determined from  $V_2 = \text{Ma}_2 c_2$ , where  $c_2$  is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.513) \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(941.6 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{772 \text{ ft/s}}$$

We now repeat the analysis for helium. This time we cannot use the tabulated values in Table A-33 since  $k$  is not 1.4. Therefore, we have to calculate the desired quantities using the analytical relations,

$$\text{Ma}_2 = \left( \frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k/(k-1) - 1} \right)^{1/2} = \left( \frac{2.5^2 + 2/(1.667-1)}{2 \times 2.5^2 \times 1.667/(1.667-1) - 1} \right)^{1/2} = \mathbf{0.553}$$

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} = \frac{1 + 1.667 \times 2.5^2}{1 + 1.667 \times 0.553^2} = 7.5632$$

$$\frac{T_2}{T_1} = \frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2} = \frac{1 + 2.5^2(1.667-1)/2}{1 + 0.553^2(1.667-1)/2} = 2.7989$$

$$\begin{aligned} \frac{P_{02}}{P_1} &= \left( \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right) \left( 1 + (k-1)\text{Ma}_2^2/2 \right)^{k/(k-1)} \\ &= \left( \frac{1 + 1.667 \times 2.5^2}{1 + 1.667 \times 0.553^2} \right) \left( 1 + (1.667-1) \times 0.553^2/2 \right)^{1.667/0.667} = 9.641 \end{aligned}$$

$$\text{Thus, } P_{02} = 11.546P_1 = (9.641)(10 \text{ psia}) = \mathbf{594 \text{ psia}}$$

$$P_2 = 7.5632P_1 = (7.5632)(10 \text{ psia}) = \mathbf{75.6 \text{ psia}}$$

$$T_2 = 2.7989T_1 = (2.7989)(440.5 \text{ R}) = \mathbf{1233 \text{ R}}$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.553) \sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(1232.9 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{2794 \text{ ft/s}}$$

**Discussion** This problem could also be solved using the relations for compressible flow and normal shock functions. The results would be identical.

**17-88E EES** Problem 17-87E is reconsidered. The effects of both air and helium flowing steadily in a nozzle when there is a normal shock at a Mach number in the range  $2 < Ma_1 < 3.5$  are to be studied. Also, the entropy change of the air and helium across the normal shock is to be calculated and the results are to be tabulated.

**Analysis** Using EES, the problem is solved as follows:

```

Procedure NormalShock(M_x,k:M_y,PyOPx, TyOTx,RhoyORhox, PoyOPox, PoyOPx)
  If M_x < 1 Then
    M_y = -1000;PyOPx=-1000;TyOTx=-1000;RhoyORhox=-1000
    PoyOPox=-1000;PoyOPx=-1000
  else
    M_y=sqrt( (M_x^2+2/(k-1)) / (2*M_x^2*k/(k-1)-1) )
    PyOPx=(1+k*M_x^2)/(1+k*M_y^2)
    TyOTx=( 1+M_x^2*(k-1)/2 )/(1+M_y^2*(k-1)/2 )
    RhoyORhox=PyOPx/TyOTx
    PoyOPox=M_x/M_y*( (1+M_y^2*(k-1)/2)/(1+M_x^2*(k-1)/2) )^((k+1)/(2*(k-1)))
    PoyOPx=(1+k*M_x^2)*(1+M_y^2*(k-1)/2)^(k/(k-1))/(1+k*M_y^2)
  Endif
End

```

```

Function ExitPress(P_back,P_crit)
  If P_back>=P_crit then ExitPress:=P_back    "Unchoked Flow Condition"
  If P_back<P_crit then ExitPress:=P_crit    "Choked Flow Condition"
End

```

```

Procedure GetProp(Gas$:Cp,k,R) "Cp and k data are from Text Table A.2E"

| 3              | 136.7                        | 120.6                         | 0.5223            | 0.4752             | 0.4223                          | 0.08                             |
| 3.5            | 184.5                        | 162.4                         | 0.5032            | 0.4512             | 0.5711                          | 0.1136                           |

**17-89** Air flowing through a nozzle experiences a normal shock. Various properties are to be calculated before and after the shock.

**Assumptions** 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Properties** The properties of air at room temperature are  $k = 1.4$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The stagnation temperature and pressure before the shock are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 217 + \frac{(680 \text{ m/s})^2}{2(1.005 \text{ kJ/kg}\cdot\text{K}) \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)} = 447.0 \text{ K}$$

$$P_{01} = P_1 \left( \frac{T_{01}}{T_1} \right)^{k/(k-1)} = (22.6 \text{ kPa}) \left( \frac{447.0 \text{ K}}{217 \text{ K}} \right)^{1.4/(1.4-1)} = 283.6 \text{ kPa}$$

The velocity and the Mach number before the shock are determined from

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(217.0 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 295.3 \text{ m/s}$$

and

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{680 \text{ m/s}}{295.3 \text{ m/s}} = 2.30$$

The fluid properties after the shock (denoted by subscript y) are related to those before the shock through the functions listed in Table A-33. For  $\text{Ma}_1 = 2.30$  we read

$$\text{Ma}_2 = 0.5344, \quad \frac{P_{02}}{P_1} = 7.2937, \quad \frac{P_2}{P_1} = 6.005, \quad \text{and} \quad \frac{T_2}{T_1} = 1.9468$$

Then the stagnation pressure  $P_{02}$ , static pressure  $P_2$ , and static temperature  $T_2$ , are determined to be

$$P_{02} = 7.2937P_1 = (7.2937)(22.6 \text{ kPa}) = 165 \text{ kPa}$$

$$P_2 = 6.005P_1 = (6.005)(22.6 \text{ kPa}) = 136 \text{ kPa}$$

$$T_2 = 1.9468T_1 = (1.9468)(217 \text{ K}) = 423 \text{ K}$$

The air velocity after the shock can be determined from  $V_2 = \text{Ma}_2 c_2$ , where  $c_2$  is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.5344) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(422.5 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 220 \text{ m/s}$$

**Discussion** This problem could also be solved using the relations for compressible flow and normal shock functions. The results would be identical.

**17-90** Air flowing through a nozzle experiences a normal shock. The entropy change of air across the normal shock wave is to be determined.

**Assumptions** **1** Air is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Properties** The properties of air at room temperature:  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (1.005 \text{ kJ/kg}\cdot\text{K}) \ln(1.9468) - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(6.005) = \mathbf{0.155 \text{ kJ/kg}\cdot\text{K}}$$

**Discussion** Note that shock wave is a highly dissipative process, and the entropy generation is large during shock waves.

**17-91 EES** The entropy change of air across the shock for upstream Mach numbers between 0.5 and 1.5 is to be determined and plotted.

**Assumptions** 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

**Properties** The properties of air are  $k = 1.4$ ,  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ , and  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$$

where

$$\text{Ma}_2 = \left( \frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k/(k-1) - 1} \right)^{1/2}$$

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2}$$

and

$$\frac{T_2}{T_1} = \frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2}$$

The results of the calculations can be tabulated as

| $\text{Ma}_1$ | $\text{Ma}_2$ | $T_2/T_1$ | $P_2/P_1$ | $s_2 - s_1$ |
|---------------|---------------|-----------|-----------|-------------|
| 0.5           | 2.6458        | 0.1250    | 0.4375    | -1.853      |
| 0.6           | 1.8778        | 0.2533    | 0.6287    | -1.247      |
| 0.7           | 1.5031        | 0.4050    | 0.7563    | -0.828      |
| 0.8           | 1.2731        | 0.5800    | 0.8519    | -0.501      |
| 0.9           | 1.1154        | 0.7783    | 0.9305    | -0.231      |
| 1.0           | 1.0000        | 1.0000    | 1.0000    | 0.0         |
| 1.1           | 0.9118        | 1.0649    | 1.2450    | 0.0003      |
| 1.2           | 0.8422        | 1.1280    | 1.5133    | 0.0021      |
| 1.3           | 0.7860        | 1.1909    | 1.8050    | 0.0061      |
| 1.4           | 0.7397        | 1.2547    | 2.1200    | 0.0124      |
| 1.5           | 0.7011        | 1.3202    | 2.4583    | 0.0210      |

**Discussion** The total entropy change is negative for upstream Mach numbers  $\text{Ma}_1$  less than unity. Therefore, normal shocks cannot occur when  $\text{Ma}_1 < 1$ .

**17-92** Supersonic airflow approaches the nose of a two-dimensional wedge and undergoes a straight oblique shock. For a specified Mach number, the minimum shock angle and the maximum deflection angle are to be determined.

**Assumptions** Air is an ideal gas with a constant specific heat ratio of  $k = 1.4$  (so that Fig. 17-41 is applicable).

**Analysis** For  $Ma = 5$ , we read from Fig. 17-41

Minimum shock (or wave) angle:  $\beta_{\min} = 12^\circ$

Maximum deflection (or turning) angle:  $\theta_{\max} = 41.5^\circ$

**Discussion** Note that the minimum shock angle decreases and the maximum deflection angle increases with increasing Mach number  $Ma_1$ .

**17-93** Air flowing at a specified supersonic Mach number impinges on a two-dimensional wedge, The shock angle, Mach number, and pressure downstream of the weak and strong oblique shock formed by a wedge are to be determined.

**Assumptions** 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e.,  $\theta \approx \delta = 12^\circ$ . Then the two values of oblique shock angle  $\beta$  are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 12^\circ = \frac{2(3.4^2 \sin^2 \beta - 1) / \tan \beta}{3.4^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in  $\beta$ . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives  $\beta_{\text{weak}} = 26.8^\circ$  and  $\beta_{\text{strong}} = 86.1^\circ$ . Then the upstream “normal” Mach number  $\text{Ma}_{1,n}$  becomes

$$\text{Weak shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 3.4 \sin 26.8^\circ = 1.531$$

$$\text{Strong shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 3.4 \sin 86.1^\circ = 3.392$$

Also, the downstream normal Mach numbers  $\text{Ma}_{2,n}$  become

$$\text{Weak shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.267)^2 + 2}{2(1.4)(1.267)^2 - 1.4 + 1}} = 0.6905$$

$$\text{Strong shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(3.392)^2 + 2}{2(1.4)(3.392)^2 - 1.4 + 1}} = 0.4555$$

The downstream pressure for each case is determined to be

$$\text{Weak shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (60 \text{ kPa}) \frac{2(1.4)(1.267)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{154 \text{ kPa}}$$

$$\text{Strong shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (60 \text{ kPa}) \frac{2(1.4)(3.392)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{796 \text{ kPa}}$$

The downstream Mach number is determined to be

$$\text{Weak shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.6905}{\sin(26.75^\circ - 12^\circ)} = \mathbf{2.71}$$

$$\text{Strong shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.4555}{\sin(86.11^\circ - 12^\circ)} = \mathbf{0.474}$$

**Discussion** Note that the change in Mach number and pressure across the *strong shock* are much greater than the changes across the *weak shock*, as expected. For both the weak and strong oblique shock cases,  $\text{Ma}_{1,n}$  is supersonic and  $\text{Ma}_{2,n}$  is subsonic. However,  $\text{Ma}_2$  is *supersonic* across the weak oblique shock, but *subsonic* across the strong oblique shock.

**17-94** Air flowing at a specified supersonic Mach number undergoes an expansion turn over a tilted wedge. The Mach number, pressure, and temperature downstream of the sudden expansion above the wedge are to be determined.

**Assumptions** 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** On the basis of Assumption #2, the deflection angle is determined to be  $\theta \approx \delta = 25^\circ - 10^\circ = 15^\circ$ . Then the upstream and downstream Prandtl-Meyer functions are determined to be

$$\nu(\text{Ma}) = \sqrt{\frac{k+1}{k-1}} \tan^{-1} \left( \sqrt{\frac{k-1}{k+1} (\text{Ma}^2 - 1)} \right) - \tan^{-1} \left( \sqrt{\text{Ma}^2 - 1} \right)$$

Upstream:

$$\nu(\text{Ma}_1) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left( \sqrt{\frac{1.4-1}{1.4+1} (2.4^2 - 1)} \right) - \tan^{-1} \left( \sqrt{2.4^2 - 1} \right) = 36.75^\circ$$

Then the downstream Prandtl-Meyer function becomes

$$\nu(\text{Ma}_2) = \theta + \nu(\text{Ma}_1) = 15^\circ + 36.75^\circ = 51.75^\circ$$

Now  $\text{Ma}_2$  is found from the Prandtl-Meyer relation, which is now implicit:

Downstream:

$$\nu(\text{Ma}_2) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left( \sqrt{\frac{1.4-1}{1.4+1} \text{Ma}_2^2 - 1} \right) - \tan^{-1} \left( \sqrt{\text{Ma}_2^2 - 1} \right) = 51.75^\circ$$

It gives  $\text{Ma}_2 = 3.105$ . Then the downstream pressure and temperature are determined from the isentropic flow relations

$$P_2 = \frac{P_2 / P_0}{P_1 / P_0} P_1 = \frac{[1 + \text{Ma}_2^2 (k-1)/2]^{-k/(k-1)}}{[1 + \text{Ma}_1^2 (k-1)/2]^{-k/(k-1)}} P_1 = \frac{[1 + 3.105^2 (1.4-1)/2]^{-1.4/0.4}}{[1 + 2.4^2 (1.4-1)/2]^{-1.4/0.4}} (70 \text{ kPa}) = \mathbf{23.8 \text{ kPa}}$$

$$T_2 = \frac{T_2 / T_0}{T_1 / T_0} T_1 = \frac{[1 + \text{Ma}_2^2 (k-1)/2]^{-1}}{[1 + \text{Ma}_1^2 (k-1)/2]^{-1}} T_1 = \frac{[1 + 3.105^2 (1.4-1)/2]^{-1}}{[1 + 2.4^2 (1.4-1)/2]^{-1}} (260 \text{ K}) = \mathbf{191 \text{ K}}$$

Note that this is an expansion, and Mach number increases while pressure and temperature decrease, as expected.

**Discussion** There are compressible flow calculators on the Internet that solve these implicit equations that arise in the analysis of compressible flow, along with both normal and oblique shock equations; e.g., see [www.aoe.vt.edu/~devenpor/aoe3114/calc.html](http://www.aoe.vt.edu/~devenpor/aoe3114/calc.html).

**17-95** Air flowing at a specified supersonic Mach number undergoes a compression turn (an oblique shock) over a tilted wedge. The Mach number, pressure, and temperature downstream of the shock below the wedge are to be determined.

**Assumptions** 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** On the basis of Assumption #2, the deflection angle is determined to be  $\theta \approx \delta = 25^\circ + 10^\circ = 35^\circ$ . Then the two values of oblique shock angle  $\beta$  are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 12^\circ = \frac{2(3.4^2 \sin^2 \beta - 1) / \tan \beta}{3.4^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in  $\beta$ . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives  $\beta_{\text{weak}} = 49.86^\circ$  and  $\beta_{\text{strong}} = 77.66^\circ$ . Then for the case of strong oblique shock, the upstream “normal” Mach number  $\text{Ma}_{1,n}$  becomes

$$\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 5 \sin 77.66^\circ = 4.884$$

Also, the downstream normal Mach numbers  $\text{Ma}_{2,n}$  become

$$\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(4.884)^2 + 2}{2(1.4)(4.884)^2 - 1.4 + 1}} = 0.4169$$

The downstream pressure and temperature are determined to be

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (70 \text{ kPa}) \frac{2(1.4)(4.884)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{1940 \text{ kPa}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (260 \text{ K}) \frac{1660 \text{ kPa}}{70 \text{ kPa}} \frac{2 + (1.4-1)(4.884)^2}{(1.4+1)(4.884)^2} = \mathbf{1450 \text{ K}}$$

The downstream Mach number is determined to be

$$\text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.4169}{\sin(77.66^\circ - 35^\circ)} = \mathbf{0.615}$$

**Discussion** Note that  $\text{Ma}_{1,n}$  is supersonic and  $\text{Ma}_{2,n}$  and  $\text{Ma}_2$  are subsonic. Also note the huge rise in temperature and pressure across the strong oblique shock, and the challenges they present for spacecraft during reentering the earth’s atmosphere.

**17-96E** Air flowing at a specified supersonic Mach number is forced to turn upward by a ramp, and weak oblique shock forms. The wave angle, Mach number, pressure, and temperature after the shock are to be determined.

**Assumptions** 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** On the basis of Assumption #2, we take the deflection angle as equal to the ramp, i.e.,  $\theta \approx \delta = 8^\circ$ . Then the two values of oblique shock angle  $\beta$  are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 8^\circ = \frac{2(2^2 \sin^2 \beta - 1) / \tan \beta}{2^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in  $\beta$ . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives  $\beta_{\text{weak}} = 37.21^\circ$  and  $\beta_{\text{strong}} = 85.05^\circ$ . Then for the case of weak oblique shock, the upstream “normal” Mach number  $\text{Ma}_{1,n}$  becomes

$$\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 37.21^\circ = 1.209$$

Also, the downstream normal Mach numbers  $\text{Ma}_{2,n}$  become

$$\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.209)^2 + 2}{2(1.4)(1.209)^2 - 1.4 + 1}} = 0.8363$$

The downstream pressure and temperature are determined to be

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (8 \text{ psia}) \frac{2(1.4)(1.209)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{12.3 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (480 \text{ R}) \frac{12.3 \text{ psia}}{8 \text{ psia}} \frac{2 + (1.4-1)(1.209)^2}{(1.4+1)(1.209)^2} = \mathbf{544 \text{ R}}$$

The downstream Mach number is determined to be

$$\text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.8363}{\sin(37.21^\circ - 8^\circ)} = \mathbf{1.71}$$

**Discussion** Note that  $\text{Ma}_{1,n}$  is supersonic and  $\text{Ma}_{2,n}$  is subsonic. However,  $\text{Ma}_2$  is *supersonic* across the weak oblique shock (it is *subsonic* across the strong oblique shock).

**17-97** Air flowing at a specified supersonic Mach number undergoes an expansion turn. The Mach number, pressure, and temperature downstream of the sudden expansion along a wall are to be determined.

**Assumptions** 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e.,  $\theta \approx \delta = 15^\circ$ . Then the upstream and downstream Prandtl-Meyer functions are determined to be

$$\nu(\text{Ma}) = \sqrt{\frac{k+1}{k-1}} \tan^{-1} \left( \sqrt{\frac{k-1}{k+1} (\text{Ma}^2 - 1)} \right) - \tan^{-1} \left( \sqrt{\text{Ma}^2 - 1} \right)$$

Upstream:

$$\nu(\text{Ma}_1) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left( \sqrt{\frac{1.4-1}{1.4+1} (3.6^2 - 1)} \right) - \tan^{-1} \left( \sqrt{3.6^2 - 1} \right) = 60.09^\circ$$

Then the downstream Prandtl-Meyer function becomes

$$\nu(\text{Ma}_2) = \theta + \nu(\text{Ma}_1) = 15^\circ + 60.09^\circ = 75.09^\circ$$

Now  $\text{Ma}_2$  is found from the Prandtl-Meyer relation, which is now implicit:

Downstream:

$$\nu(\text{Ma}_2) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left( \sqrt{\frac{1.4-1}{1.4+1} \text{Ma}_2^2 - 1} \right) - \tan^{-1} \left( \sqrt{\text{Ma}_2^2 - 1} \right) = 75.09^\circ$$

It gives  $\text{Ma}_2 = 4.81$ . Then the downstream pressure and temperature are determined from the isentropic flow relations

$$P_2 = \frac{P_2 / P_0}{P_1 / P_0} P_1 = \frac{[1 + \text{Ma}_2^2 (k-1)/2]^{-k/(k-1)}}{[1 + \text{Ma}_1^2 (k-1)/2]^{-k/(k-1)}} P_1 = \frac{[1 + 4.81^2 (1.4-1)/2]^{-1.4/0.4}}{[1 + 3.6^2 (1.4-1)/2]^{-1.4/0.4}} (40 \text{ kPa}) = \mathbf{8.31 \text{ kPa}}$$

$$T_2 = \frac{T_2 / T_0}{T_1 / T_0} T_1 = \frac{[1 + \text{Ma}_2^2 (k-1)/2]^{-1}}{[1 + \text{Ma}_1^2 (k-1)/2]^{-1}} T_1 = \frac{[1 + 4.81^2 (1.4-1)/2]^{-1}}{[1 + 3.6^2 (1.4-1)/2]^{-1}} (280 \text{ K}) = \mathbf{179 \text{ K}}$$

Note that this is an expansion, and Mach number increases while pressure and temperature decrease, as expected.

**Discussion** There are compressible flow calculators on the Internet that solve these implicit equations that arise in the analysis of compressible flow, along with both normal and oblique shock equations; e.g., see [www.aoe.vt.edu/~devenpor/aoe3114/calc.html](http://www.aoe.vt.edu/~devenpor/aoe3114/calc.html).

**17-98E** Air flowing at a specified supersonic Mach number is forced to undergo a compression turn (an oblique shock). The Mach number, pressure, and temperature downstream of the oblique shock are to be determined.

**Assumptions** 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

**Properties** The specific heat ratio of air is  $k = 1.4$  (Table A-2a).

**Analysis** On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e.,  $\theta \approx \delta = 15^\circ$ . Then the two values of oblique shock angle  $\beta$  are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 15^\circ = \frac{2(2^2 \sin^2 \beta - 1) / \tan \beta}{2^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in  $\beta$ . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives  $\beta_{\text{weak}} = 45.34^\circ$  and  $\beta_{\text{strong}} = 79.83^\circ$ . Then the upstream “normal” Mach number  $\text{Ma}_{1,n}$  becomes

**Weak shock:**  $\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 45.34^\circ = 1.423$

**Strong shock:**  $\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 79.83^\circ = 1.969$

Also, the downstream normal Mach numbers  $\text{Ma}_{2,n}$  become

**Weak shock:**  $\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.423)^2 + 2}{2(1.4)(1.423)^2 - 1.4 + 1}} = 0.7304$

**Strong shock:**  $\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.969)^2 + 2}{2(1.4)(1.969)^2 - 1.4 + 1}} = 0.5828$

The downstream pressure and temperature for each case are determined to be

**Weak shock:**

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (6 \text{ psia}) \frac{2(1.4)(1.423)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{13.2 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (480 \text{ R}) \frac{13.2 \text{ psia}}{6 \text{ psia}} \frac{2 + (1.4-1)(1.423)^2}{(1.4+1)(1.423)^2} = \mathbf{609 \text{ R}}$$

**Strong shock:**

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (6 \text{ psia}) \frac{2(1.4)(1.969)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{26.1 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)Ma_{1,n}^2}{(k+1)Ma_{1,n}^2} = (480 \text{ R}) \frac{26.1 \text{ psia}}{6 \text{ psia}} \frac{2 + (1.4-1)(1.969)^2}{(1.4+1)(1.969)^2} = \mathbf{798 \text{ R}}$$

The downstream Mach number is determined to be

$$\text{Weak shock:} \quad Ma_2 = \frac{Ma_{2,n}}{\sin(\beta - \theta)} = \frac{0.7304}{\sin(45.34^\circ - 15^\circ)} = \mathbf{1.45}$$

$$\text{Strong shock:} \quad Ma_2 = \frac{Ma_{2,n}}{\sin(\beta - \theta)} = \frac{0.5828}{\sin(79.83^\circ - 15^\circ)} = \mathbf{0.644}$$

**Discussion** Note that the change in Mach number, pressure, temperature across the *strong shock* are much greater than the changes across the *weak shock*, as expected. For both the weak and strong oblique shock cases,  $Ma_{1,n}$  is supersonic and  $Ma_{2,n}$  is subsonic. However,  $Ma_2$  is *supersonic* across the weak oblique shock, but *subsonic* across the strong oblique shock.

**Duct Flow with Heat Transfer and Negligible Friction (Rayleigh Flow)**

**17-99C** The characteristic aspect of Rayleigh flow is its involvement of heat transfer. The main assumptions associated with Rayleigh flow are: the flow is steady, one-dimensional, and frictionless through a constant-area duct, and the fluid is an ideal gas with constant specific heats.

**117-100C** The points on the Rayleigh line represent the states that satisfy the conservation of mass, momentum, and energy equations as well as the property relations for a given state. Therefore, for a given inlet state, the fluid cannot exist at any downstream state outside the Rayleigh line on a  $T$ - $s$  diagram.

**17-101C** In Rayleigh flow, the effect of heat gain is to increase the entropy of the fluid, and the effect of heat loss is to decrease it.

**17-102C** In Rayleigh flow, the stagnation temperature  $T_0$  always increases with heat transfer to the fluid, but the temperature  $T$  decreases with heat transfer in the Mach number range of  $0.845 < Ma < 1$  for air. Therefore, the temperature in this case will decrease.

**17-103C** Heating the fluid increases the flow velocity in subsonic flow, but decreases the flow velocity in supersonic flow.

**17-104C** The flow is choked, and thus the flow at the duct exit will remain sonic.

**17-105** Fuel is burned in a tubular combustion chamber with compressed air. For a specified exit Mach number, the exit temperature and the rate of fuel consumption are to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Combustion is complete, and it is treated as a heat addition process, with no change in the chemical composition of flow. **3** The increase in mass flow rate due to fuel injection is disregarded.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The inlet density and mass flow rate of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{400 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(500 \text{ K})} = 2.787 \text{ kg/m}^3$$

$$\begin{aligned}\dot{m}_{\text{air}} &= \rho_1 A_{c1} V_1 \\ &= (2.787 \text{ kg/m}^3) [\pi (0.12 \text{ m})^2 / 4] (70 \text{ m/s}) \\ &= 2.207 \text{ kg/s}\end{aligned}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 500 \text{ K} + \frac{(70 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 502.4 \text{ K}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(500 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 448.2 \text{ m/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{70 \text{ m/s}}{448.2 \text{ m/s}} = 0.1562$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.1562: \quad T_1/T^* = 0.1314, \quad T_{01}/T^* = 0.1100, \quad V_1/V^* = 0.0566$$

$$\text{Ma}_2 = 0.8: \quad T_2/T^* = 1.0255, \quad T_{02}/T^* = 0.9639, \quad V_2/V^* = 0.8101$$

The exit temperature, stagnation temperature, and velocity are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1.0255}{0.1314} = 7.804 \quad \rightarrow \quad T_2 = 7.804 T_1 = 7.804(500 \text{ K}) = \mathbf{3903 \text{ K}}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{0.9639}{0.1100} = 8.763 \quad \rightarrow \quad T_{02} = 8.763 T_{01} = 8.763(502.4 \text{ K}) = 4403 \text{ K}$$

$$\frac{V_2}{V_1} = \frac{V_2/V^*}{V_1/V^*} = \frac{0.8101}{0.0566} = 14.31 \quad \rightarrow \quad V_2 = 14.31 V_1 = 14.31(70 \text{ m/s}) = 1002 \text{ m/s}$$

Then the mass flow rate of the fuel is determined to be

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(4403 - 502.4) \text{ K} = 3920 \text{ kJ/kg}$$

$$\dot{Q} = \dot{m}_{\text{air}} q = (2.207 \text{ kg/s})(3920 \text{ kJ/kg}) = 8650 \text{ kW}$$

$$\dot{m}_{\text{fuel}} = \frac{\dot{Q}}{\text{HV}} = \frac{8650 \text{ kJ/s}}{39,000 \text{ kJ/kg}} = \mathbf{0.222 \text{ kg/s}}$$

**Discussion** Note that both the temperature and velocity increase during this subsonic Rayleigh flow with heating, as expected. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

**17-106** Fuel is burned in a rectangular duct with compressed air. For specified heat transfer, the exit temperature and Mach number are to be determined.

**Assumptions** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ , and  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** The stagnation temperature and Mach number at the inlet are

$$\begin{aligned} c_1 &= \sqrt{kRT_1} \\ &= \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(300 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} \\ &= 347.2 \text{ m/s} \end{aligned}$$

$$V_1 = \text{Ma}_1 c_1 = 2(347.2 \text{ m/s}) = 694.4 \text{ m/s}$$

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 300 \text{ K} + \frac{(694.4 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg} \cdot \text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 539.9 \text{ K}$$

The exit stagnation temperature is, from the energy equation  $q = c_p (T_{02} - T_{01})$ ,

$$T_{02} = T_{01} + \frac{q}{c_p} = 539.9 \text{ K} + \frac{55 \text{ kJ/kg}}{1.005 \text{ kJ/kg} \cdot \text{K}} = 594.6 \text{ K}$$

The maximum value of stagnation temperature  $T_0^*$  occurs at  $\text{Ma} = 1$ , and its value can be determined from Table A-34 or from the appropriate relation. At  $\text{Ma}_1 = 2$  we read  $T_{01}/T_0^* = 0.7934$ . Therefore,

$$T_0^* = \frac{T_{01}}{0.7934} = \frac{539.9 \text{ K}}{0.7934} = 680.5 \text{ K}$$

The stagnation temperature ratio at the exit and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{02}}{T_0^*} = \frac{594.6 \text{ K}}{680.5 \text{ K}} = 0.8738 \quad \rightarrow \quad \text{Ma}_2 = \mathbf{1.642}$$

Also,

$$\text{Ma}_1 = 2 \quad \rightarrow \quad T_1/T^* = 0.5289$$

$$\text{Ma}_2 = 1.642 \quad \rightarrow \quad T_2/T^* = 0.6812$$

Then the exit temperature becomes

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{0.6812}{0.5289} = 1.288 \quad \rightarrow \quad T_2 = 1.288 T_1 = 1.288(300 \text{ K}) = \mathbf{386 \text{ K}}$$

**Discussion** Note that the temperature increases during this supersonic Rayleigh flow with heating. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

**17-107** Compressed air is cooled as it flows in a rectangular duct. For specified heat rejection, the exit temperature and Mach number are to be determined.

**Assumptions** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ , and  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** The stagnation temperature and Mach number at the inlet are

$$\begin{aligned} c_1 &= \sqrt{kRT_1} \\ &= \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(300 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} \\ &= 347.2 \text{ m/s} \end{aligned}$$

$$V_1 = \text{Ma}_1 c_1 = 2(347.2 \text{ m/s}) = 694.4 \text{ m/s}$$

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 300 \text{ K} + \frac{(694.4 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg} \cdot \text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 539.9 \text{ K}$$

The exit stagnation temperature is, from the energy equation  $q = c_p(T_{02} - T_{01})$ ,

$$T_{02} = T_{01} + \frac{q}{c_p} = 539.9 \text{ K} + \frac{-55 \text{ kJ/kg}}{1.005 \text{ kJ/kg} \cdot \text{K}} = 485.2 \text{ K}$$

The maximum value of stagnation temperature  $T_0^*$  occurs at  $\text{Ma} = 1$ , and its value can be determined from Table A-34 or from the appropriate relation. At  $\text{Ma}_1 = 2$  we read  $T_{01}/T_0^* = 0.7934$ . Therefore,

$$T_0^* = \frac{T_{01}}{0.7934} = \frac{539.9 \text{ K}}{0.7934} = 680.5 \text{ K}$$

The stagnation temperature ratio at the exit and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{02}}{T_0^*} = \frac{485.2 \text{ K}}{680.5 \text{ K}} = 0.7130 \quad \rightarrow \quad \text{Ma}_2 = 2.479$$

Also,

$$\text{Ma}_1 = 2 \quad \rightarrow \quad T_1/T^* = 0.5289$$

$$\text{Ma}_2 = 2.479 \quad \rightarrow \quad T_2/T^* = 0.3838$$

Then the exit temperature becomes

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{0.3838}{0.5289} = 0.7257 \quad \rightarrow \quad T_2 = 0.7257 T_1 = 0.7257(300 \text{ K}) = \mathbf{218 \text{ K}}$$

**Discussion** Note that the temperature decreases and Mach number increases during this supersonic Rayleigh flow with cooling. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

**17-108** Air is heated in a duct during subsonic flow until it is choked. For specified pressure and velocity at the exit, the temperature, pressure, and velocity at the inlet are to be determined.

**Assumptions** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ , and  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** Noting that sonic conditions exist at the exit, the exit temperature is

$$c_2 = V_2 / \text{Ma}_2 = (620 \text{ m/s}) / 1 = 620 \text{ m/s}$$

$$c_2 = \sqrt{kRT_2}$$

$$620 \text{ m/s} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})T_2 \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

It gives  $T_2 = 956.7 \text{ K}$ . Then the exit stagnation temperature becomes

$$T_{02} = T_2 + \frac{V_2^2}{2c_p} = 956.7 \text{ K} + \frac{(620 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg} \cdot \text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 1148 \text{ K}$$

The inlet stagnation temperature is, from the energy equation  $q = c_p(T_{02} - T_{01})$ ,

$$T_{01} = T_{02} - \frac{q}{c_p} = 1148 \text{ K} - \frac{60 \text{ kJ/kg}}{1.005 \text{ kJ/kg} \cdot \text{K}} = 1088 \text{ K}$$

The maximum value of stagnation temperature  $T_0^*$  occurs at  $\text{Ma} = 1$ , and its value in this case is  $T_{02}$  since the flow is choked. Therefore,  $T_0^* = T_{02} = 1148 \text{ K}$ . Then the stagnation temperature ratio at the inlet, and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{01}}{T_0^*} = \frac{1088 \text{ K}}{1148 \text{ K}} = 0.9478 \quad \rightarrow \quad \text{Ma}_1 = \mathbf{0.7649}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.7649: \quad T_1/T^* = 1.017, \quad P_1/P^* = 1.319, \quad V_1/V^* = 0.7719$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad V_2/V^* = 1$$

Then the inlet temperature, pressure, and velocity are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{1.017} \quad \rightarrow \quad T_1 = 1.017T_2 = 1.017(956.7 \text{ K}) = \mathbf{974 \text{ K}}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{1.319} \quad \rightarrow \quad P_1 = 1.319P_2 = 1.319(270 \text{ kPa}) = \mathbf{356 \text{ kPa}}$$

$$\frac{V_2}{V_1} = \frac{V_2/V^*}{V_1/V^*} = \frac{1}{0.7719} \quad \rightarrow \quad V_1 = 0.7719V_2 = 0.7719(620 \text{ m/s}) = \mathbf{479 \text{ m/s}}$$

**Discussion** Note that the temperature and pressure decreases with heating during this subsonic Rayleigh flow while velocity increases. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

**17-109E** Air flowing with a subsonic velocity in a round duct is accelerated by heating until the flow is choked at the exit. The rate of heat transfer and the pressure drop are to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The flow is choked at the duct exit. **3** Mass flow rate remains constant.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 0.2400 \text{ Btu/lbm} \cdot \text{R}$ , and  $R = 0.06855 \text{ Btu/lbm} \cdot \text{R} = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-2Ea).

**Analysis** The inlet density and velocity of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{30 \text{ psia}}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(800 \text{ R})} = 0.1012 \text{ lbm/ft}^3$$

$$V_1 = \frac{\dot{m}_{\text{air}}}{\rho_1 A_{c1}} = \frac{5 \text{ lbm/s}}{(0.1012 \text{ lbm/ft}^3)[\pi(4/12 \text{ ft})^2/4]} = 565.9 \text{ ft/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 800 \text{ R} + \frac{(565.9 \text{ ft/s})^2}{2 \times 0.2400 \text{ Btu/lbm} \cdot \text{R}} \left( \frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 826.7 \text{ R}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(800 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1386 \text{ ft/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{565.9 \text{ ft/s}}{1386 \text{ ft/s}} = 0.4082$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.4082: \quad T_1/T^* = 0.6310, \quad P_1/P^* = 1.946, \quad T_{01}/T_0^* = 0.5434$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature, pressure, and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.6310} \quad \rightarrow \quad T_2 = T_1 / 0.6310 = (800 \text{ R}) / 0.6310 = 1268 \text{ R}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{1.946} \quad \rightarrow \quad P_2 = P_1 / 1.946 = (30 \text{ psia}) / 1.946 = 15.4 \text{ psia}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.5434} \quad \rightarrow \quad T_{02} = T_{01} / 0.5434 = (826.7 \text{ R}) / 0.5434 = 1521 \text{ R}$$

Then the rate of heat transfer and the pressure drop become

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (5 \text{ lbm/s})(0.2400 \text{ Btu/lbm} \cdot \text{R})(1521 - 826.7) \text{ R} = \mathbf{834 \text{ Btu/s}}$$

$$\Delta P = P_1 - P_2 = 30 - 15.4 = \mathbf{14.6 \text{ psia}}$$

**Discussion** Note that the entropy of air increases during this heating process, as expected.

**17-110 EES** Air flowing with a subsonic velocity in a duct. The variation of entropy with temperature is to be investigated as the exit temperature varies from 600 K to 5000 K in increments of 200 K. The results are to be tabulated and plotted.

**Analysis** We solve this problem using EES making use of Rayleigh functions as follows:

```

k=1.4
cp=1.005
R=0.287

P1=350
T1=600
V1=70
C1=sqrt(k*R*T1*1000)
Ma1=V1/C1

T01=T1*(1+0.5*(k-1)*Ma1^2)
P01=P1*(1+0.5*(k-1)*Ma1^2)^(k/(k-1))

F1=1+0.5*(k-1)*Ma1^2
T01Ts=2*(k+1)*Ma1^2*F1/(1+k*Ma1^2)^2
P01Ps=((1+k)/(1+k*Ma1^2))^(2*F1/(k+1))^(k/(k-1))
T1Ts=(Ma1*((1+k)/(1+k*Ma1^2)))^2
P1Ps=(1+k)/(1+k*Ma1^2)
V1Vs=Ma1^2*(1+k)/(1+k*Ma1^2)

F2=1+0.5*(k-1)*Ma2^2
T02Ts=2*(k+1)*Ma2^2*F2/(1+k*Ma2^2)^2
P02Ps=((1+k)/(1+k*Ma2^2))^(2*F2/(k+1))^(k/(k-1))
T2Ts=(Ma2*((1+k)/(1+k*Ma2^2)))^2
P2Ps=(1+k)/(1+k*Ma2^2)
V2Vs=Ma2^2*(1+k)/(1+k*Ma2^2)

T02=T02Ts/T01Ts*T01
P02=P02Ps/P01Ps*P01
T2=T2Ts/T1Ts*T1
P2=P2Ps/P1Ps*P1
V2=V2Vs/V1Vs*V1
Delta_s=cp*ln(T2/T1)-R*ln(P2/P1)

```

**17-111E** Air flowing with a subsonic velocity in a square duct is accelerated by heating until the flow is choked at the exit. The rate of heat transfer and the entropy change are to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The flow is choked at the duct exit. **3** Mass flow rate remains constant.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$ , and  $R = 0.06855 \text{ Btu/lbm} \cdot \text{R} = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$  (Table A-2Ea).

**Analysis** The inlet density and mass flow rate of air are

$$\begin{aligned}\rho_1 &= \frac{P_1}{RT_1} \\ &= \frac{80 \text{ psia}}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(700 \text{ R})} \\ &= 0.3085 \text{ lbm/ft}^3\end{aligned}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (0.3085 \text{ lbm/ft}^3)(4 \times 4/144 \text{ ft}^2)(260 \text{ ft/s}) = 8.914 \text{ lbm/s}$$

The stagnation temperature and Mach number at the inlet are

$$\begin{aligned}T_{01} &= T_1 + \frac{V_1^2}{2c_p} = 700 \text{ R} + \frac{(260 \text{ ft/s})^2}{2 \times 0.240 \text{ Btu/lbm} \cdot \text{R}} \left( \frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 705.6 \text{ R} \\ c_1 &= \sqrt{kRT_1} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(700 \text{ R})} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) = 1297 \text{ ft/s} \\ \text{Ma}_1 &= \frac{V_1}{c_1} = \frac{260 \text{ ft/s}}{1297 \text{ ft/s}} = 0.2005\end{aligned}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\begin{aligned}\text{Ma}_1 = 0.2005: \quad T_1/T^* &= 0.2075, \quad P_1/P^* = 2.272, \quad T_{01}/T_0^* = 0.1743 \\ \text{Ma}_2 = 1: \quad T_2/T^* &= 1, \quad P_2/P^* = 1, \quad T_{02}/T_0^* = 1\end{aligned}$$

Then the exit temperature, pressure, and stagnation temperature are determined to be

$$\begin{aligned}\frac{T_2}{T_1} &= \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.2075} \quad \rightarrow \quad T_2 = T_1 / 0.2075 = (700 \text{ R}) / 0.2075 = 3374 \text{ R} \\ \frac{P_2}{P_1} &= \frac{P_2/P^*}{P_1/P^*} = \frac{1}{2.272} \quad \rightarrow \quad P_2 = P_1 / 2.272 = (80 \text{ psia}) / 2.272 = 35.2 \text{ psia} \\ \frac{T_{02}}{T_{01}} &= \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.1743} \quad \rightarrow \quad T_{02} = T_{01} / 0.1743 = (705.6 \text{ R}) / 0.1743 = 4048 \text{ R}\end{aligned}$$

Then the rate of heat transfer and entropy change become

$$\begin{aligned}\dot{Q} &= \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (8.914 \text{ lbm/s})(0.240 \text{ Btu/lbm} \cdot \text{R})(4048 - 705.6) \text{ R} = \mathbf{7151 \text{ Btu/s}} \\ \Delta s &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (0.240 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{3374 \text{ R}}{700 \text{ R}} - (0.06855 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{35.2 \text{ psia}}{80 \text{ psia}} = \mathbf{0.434 \text{ Btu/lbm} \cdot \text{R}}\end{aligned}$$

**Discussion** Note that the entropy of air increases during this heating process, as expected.

**17-112** Air enters the combustion chamber of a gas turbine at a subsonic velocity. For a specified rate of heat transfer, the Mach number at the exit and the loss in stagnation pressure to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The cross-sectional area of the combustion chamber is constant. **3** The increase in mass flow rate due to fuel injection is disregarded.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ , and  $R = 0.287 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** The inlet stagnation temperature and pressure are

$$T_{01} = T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (550 \text{ K}) \left( 1 + \frac{1.4-1}{2} 0.2^2 \right) = 554.4 \text{ K}$$

$$P_{01} = P_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{k/(k-1)} = (600 \text{ kPa}) \left( 1 + \frac{1.4-1}{2} 0.2^2 \right)^{1.4/0.4} = 617.0 \text{ kPa}$$

The exit stagnation temperature is determined from

$$\begin{aligned} \dot{Q} &= \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) \\ 200 \text{ kJ/s} &= (0.3 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(T_{02} - 554.4 \text{ K}) \end{aligned}$$

It gives

$$T_{02} = 1218 \text{ K.}$$

At  $\text{Ma}_1 = 0.2$  we read from  $T_{01}/T_0^* = 0.1736$  (Table A-34).

Therefore,

$$T_0^* = \frac{T_{01}}{0.1736} = \frac{554.4 \text{ K}}{0.1736} = 3193.5 \text{ K}$$

Then the stagnation temperature ratio at the exit and the Mach number corresponding to it are (Table A-34)

$$\frac{T_{02}}{T_0^*} = \frac{1218 \text{ K}}{3193.5 \text{ K}} = 0.3814 \quad \rightarrow \quad \text{Ma}_2 = \mathbf{0.3187}$$

Also,

$$\text{Ma}_1 = 0.2 \quad \rightarrow \quad P_{01}/P_0^* = 1.2346$$

$$\text{Ma}_2 = 0.3187 \quad \rightarrow \quad P_{02}/P_0^* = 1.191$$

Then the stagnation pressure at the exit and the pressure drop become

$$\frac{P_{02}}{P_{01}} = \frac{P_{02}/P_0^*}{P_{01}/P_0^*} = \frac{1.191}{1.2346} = 0.9647 \quad \rightarrow \quad P_{02} = 0.9647 P_{01} = 0.9647(617 \text{ kPa}) = 595.2 \text{ kPa}$$

$$\text{and} \quad \Delta P_0 = P_{01} - P_{02} = 617.0 - 595.2 = \mathbf{21.8 \text{ kPa}}$$

**Discussion** This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

**17-113** Air enters the combustion chamber of a gas turbine at a subsonic velocity. For a specified rate of heat transfer, the Mach number at the exit and the loss in stagnation pressure to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The cross-sectional area of the combustion chamber is constant. **3** The increase in mass flow rate due to fuel injection is disregarded.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The inlet stagnation temperature and pressure are

$$T_{01} = T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (550 \text{ K}) \left( 1 + \frac{1.4-1}{2} 0.2^2 \right) = 554.4 \text{ K}$$

$$P_{01} = P_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{k/(k-1)} = (600 \text{ kPa}) \left( 1 + \frac{1.4-1}{2} 0.2^2 \right)^{1.4/0.4} = 617.0 \text{ kPa}$$

The exit stagnation temperature is determined from

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) \rightarrow 300 \text{ kJ/s} = (0.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(T_{02} - 554.4 \text{ K})$$

It gives

$$T_{02} = 1549 \text{ K.}$$

At  $\text{Ma}_1 = 0.2$  we read from  $T_{01}/T_0^* = 0.1736$  (Table A-34). Therefore,

$$T_0^* = \frac{T_{01}}{0.1736} = \frac{554.4 \text{ K}}{0.1736} = 3193.5 \text{ K}$$

Then the stagnation temperature ratio at the exit and the Mach number corresponding to it are (Table A-34)

$$\frac{T_{02}}{T_0^*} = \frac{1549 \text{ K}}{3193.5 \text{ K}} = 0.4850 \rightarrow \text{Ma}_2 = \mathbf{0.3753}$$

Also,

$$\text{Ma}_1 = 0.2 \rightarrow P_{01}/P_0^* = 1.2346$$

$$\text{Ma}_2 = 0.3753 \rightarrow P_{02}/P_0^* = 1.167$$

Then the stagnation pressure at the exit and the pressure drop become

$$\frac{P_{02}}{P_{01}} = \frac{P_{02}/P_0^*}{P_{01}/P_0^*} = \frac{1.167}{1.2346} = 0.9452 \rightarrow P_{02} = 0.9452 P_{01} = 0.9452(617 \text{ kPa}) = 583.3 \text{ kPa}$$

and

$$\Delta P_0 = P_{01} - P_{02} = 617.0 - 583.3 = \mathbf{33.7 \text{ kPa}}$$

**Discussion** This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

**17-114** Argon flowing at subsonic velocity in a constant-diameter duct is accelerated by heating. The highest rate of heat transfer without reducing the mass flow rate is to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Mass flow rate remains constant.

**Properties** We take the properties of argon to be  $k = 1.667$ ,  $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Heat transfer will stop when the flow is choked, and thus  $\text{Ma}_2 = V_2/c_2 = 1$ . The inlet stagnation temperature is

$$\begin{aligned} T_{01} &= T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) \\ &= (400 \text{ K}) \left( 1 + \frac{1.667-1}{2} 0.2^2 \right) \\ &= 405.3 \text{ K} \end{aligned}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \quad (\text{since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.667+1)0.2^2 [2 + (1.667-1)0.2^2]}{(1+1.667 \times 0.2^2)^2} = 0.1900$$

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.1900} \quad \rightarrow \quad T_{02} = T_{01} / 0.1900 = (405.3 \text{ K}) / 0.1900 = 2133 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (0.8 \text{ kg/s})(0.5203 \text{ kJ/kg}\cdot\text{K})(2133 - 400) \text{ K} = \mathbf{721 \text{ kW}}$$

**Discussion** It can also be shown that  $T_2 = 1600 \text{ K}$ , which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. Also, in the solution of this problem, we cannot use the values of Table A-34 since they are based on  $k = 1.4$ .

**17-115** Air flowing at a supersonic velocity in a duct is decelerated by heating. The highest temperature air can be heated by heat addition and the rate of heat transfer are to be determined.

**Assumptions** 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Mass flow rate remains constant.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Heat transfer will stop when the flow is choked, and thus  $\text{Ma}_2 = V_2/c_2 = 1$ . Knowing stagnation properties, the static properties are determined to be

$$T_1 = T_{01} \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-1} = (600 \text{ K}) \left( 1 + \frac{1.4-1}{2} 1.8^2 \right)^{-1} = 364.1 \text{ K}$$

$$P_1 = P_{01} \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-k/(k-1)} = (210 \text{ kPa}) \left( 1 + \frac{1.4-1}{2} 1.8^2 \right)^{-1.4/0.4} = 36.55 \text{ kPa}$$

$$\rho_1 = \frac{P_1}{RT_1} = \frac{36.55 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(364.1 \text{ K})} = 0.3498 \text{ kg/m}^3$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(364.1 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 382.5 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 1.8(382.5 \text{ m/s}) = 688.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (0.3498 \text{ kg/m}^3) [\pi (0.06 \text{ m})^2 / 4] (688.5 \text{ m/s}) = 0.6809 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1.8: \quad T_1/T^* = 0.6089, \quad T_{01}/T_0^* = 0.8363$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.6089} \quad \rightarrow \quad T_2 = T_1 / 0.6089 = (364.1 \text{ K}) / 0.6089 = \mathbf{598 \text{ K}}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.8363} \quad \rightarrow \quad T_{02} = T_{01} / 0.8363 = (600 \text{ K}) / 0.8363 = \mathbf{717.4 \text{ K}}$$

Finally, the rate of heat transfer is

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (0.6809 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(717.4 - 600) \text{ K} = \mathbf{80.3 \text{ kW}}$$

**Discussion** Note that this is the highest temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature will cause the mass flow rate to decrease. Also, once the sonic conditions are reached, the thermodynamic temperature can be increased further by cooling the fluid and reducing the velocity (see the  $T$ - $s$  diagram for Rayleigh flow).

**Steam Nozzles**

**17-116C** The delay in the condensation of the steam is called supersaturation. It occurs in high-speed flows where there isn't sufficient time for the necessary heat transfer and the formation of liquid droplets.

**17-117** Steam enters a converging nozzle with a low velocity. The exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

**Assumptions** 1 Flow through the nozzle is steady and one-dimensional. 2 The nozzle is adiabatic.

**Analysis** (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{01} = h_1$ .

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} = 3 \text{ MPa} \\ T_1 = T_{01} = 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 = h_{01} = 3457.2 \text{ kJ/kg} \\ s_1 = s_{2s} = 7.2359 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At the exit,

$$\left. \begin{aligned} P_2 = 1.8 \text{ MPa} \\ s_2 = 7.2359 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \begin{aligned} h_2 = 3288.7 \text{ kJ/kg} \\ v_2 = 0.1731 \text{ m}^3/\text{kg} \end{aligned}$$

Then the exit velocity is determined from the steady-flow energy balance  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  with  $q = w = 0$ ,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3457.2 - 3288.7) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{580.4 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.1731 \text{ m}^3/\text{kg}} (32 \times 10^{-4} \text{ m}^2) (580.4 \text{ m/s}) = \mathbf{10.73 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left( \frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at  $s_2 = 7.2359 \text{ kJ/kg} \cdot \text{K}$  and at pressures just below and just above the specified pressure (1.6 and 2.0 MPa) are determined to be 0.1897 and 0.1595  $\text{m}^3/\text{kg}$ . Substituting,

$$c_2 = \sqrt{\frac{(2000 - 1600) \text{ kPa}}{\left( \frac{1}{0.1595} - \frac{1}{0.1897} \right) \text{ kg/m}^3} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 632.7 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{580.4 \text{ m/s}}{632.7 \text{ m/s}} = \mathbf{0.918}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{01} = h_1$ .

At the inlet,

$$\left. \begin{aligned} P_1 &= P_{01} = 3 \text{ MPa} \\ T_1 &= T_{01} = 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &= h_{01} = 3457.2 \text{ kJ/kg} \\ s_1 &= s_{2s} = 7.2359 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At state 2s,

$$\left. \begin{aligned} P_{2s} &= 1.8 \text{ MPa} \\ s_{2s} &= 7.2359 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} h_{2s} = 3288.7 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.90 = \frac{3457.2 - h_2}{3457.2 - 3288.7} \longrightarrow h_2 = 3305.6 \text{ kJ/kg}$$

Therefore,

$$\left. \begin{aligned} P_2 &= 1.8 \text{ MPa} \\ h_2 &= 3305.6 \text{ kJ/kg} \end{aligned} \right\} \begin{aligned} v_2 &= 0.1752 \text{ m}^3/\text{kg} \\ s_2 &= 7.2602 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Then the exit velocity is determined from the steady-flow energy balance  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  with  $q = w = 0$ ,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3457.2 - 3305.6) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 550.7 \text{ m/s}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.1752 \text{ m}^3/\text{kg}} (32 \times 10^{-4} \text{ m}^2) (550.7 \text{ m/s}) = 10.06 \text{ kg/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial P}{\partial \rho} \right)_s \cong \left( \frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at  $s_2 = 7.2602 \text{ kJ/kg} \cdot \text{K}$  and at pressures just below and just above the specified pressure (1.6 and 2.0 MPa) are determined to be 0.1921 and 0.1614  $\text{m}^3/\text{kg}$ . Substituting,

$$c_2 = \sqrt{\frac{(2000 - 1600) \text{ kPa}}{\left( \frac{1}{0.1614} - \frac{1}{0.1921} \right) \text{ kg/m}^3} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 636.3 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{550.7 \text{ m/s}}{636.3 \text{ m/s}} = 0.865$$

**17-118E** Steam enters a converging nozzle with a low velocity. The exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

**Assumptions** 1 Flow through the nozzle is steady and one-dimensional. 2 The nozzle is adiabatic.

**Analysis** (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{01} = h_1$ .

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} &= 450 \text{ psia} \\ T_1 = T_{01} &= 900^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_1 &= h_{01} = 1468.6 \text{ Btu/lbm} \\ s_1 &= s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

At the exit,

$$\left. \begin{aligned} P_2 &= 275 \text{ psia} \\ s_{2s} &= 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \right\} \begin{aligned} h_2 &= 1400.5 \text{ Btu/lbm} \\ v_2 &= 2.5732 \text{ ft}^3/\text{lbm} \end{aligned}$$

- a)  $\eta_N = 100\%$   
b)  $\eta_N = 90\%$

Then the exit velocity is determined from the steady-flow energy balance  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  with  $q = w = 0$ ,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(1468.6 - 1400.5) \text{ Btu/lbm} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{1847 \text{ ft/s}}$$

Then,

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{2.5732 \text{ ft}^3/\text{lbm}} (3.75/144 \text{ ft}^2) (1847 \text{ ft/s}) = \mathbf{18.7 \text{ lbm/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left( \frac{\Delta P}{\Delta(1/v)} \right)_s$$

The specific volume of steam at  $s_2 = 1.7117 \text{ Btu/lbm} \cdot \text{R}$  and at pressures just below and just above the specified pressure (250 and 300 psia) are determined to be 2.7709 and 2.4048  $\text{ft}^3/\text{lbm}$ . Substituting,

$$c_2 = \sqrt{\frac{(300 - 250) \text{ psia}}{\left( \frac{1}{2.4048} - \frac{1}{2.7709} \right) \text{ lbm/ft}^3} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \left( \frac{1 \text{ Btu}}{5.4039 \text{ ft}^3 \cdot \text{psia}} \right)} = 2053 \text{ ft/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1847 \text{ ft/s}}{2053 \text{ ft/s}} = \mathbf{0.900}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{01} = h_1$ .

At the inlet,

$$\left. \begin{aligned} P_1 &= P_{01} = 450 \text{ psia} \\ T_1 &= T_{01} = 900^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_1 &= h_{01} = 1468.6 \text{ Btu/lbm} \\ s_1 &= s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

At state 2s,

$$\left. \begin{aligned} P_{2s} &= 275 \text{ psia} \\ s_{2s} &= 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \right\} h_{2s} = 1400.5 \text{ Btu/lbm}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.90 = \frac{1468.6 - h_2}{1468.6 - 1400.5} \longrightarrow h_2 = 1407.3 \text{ Btu/lbm}$$

Therefore,

$$\left. \begin{aligned} P_2 &= 275 \text{ psia} \\ h_2 &= 1407.3 \text{ Btu/lbm} \end{aligned} \right\} \begin{aligned} v_2 &= 2.6034 \text{ ft}^3/\text{lbm} \\ s_2 &= 1.7173 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

Then the exit velocity is determined from the steady-flow energy balance  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  with  $q = w = 0$ ,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(1468.6 - 1407.3) \text{ Btu/lbm} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{1752 \text{ ft/s}}$$

Then,

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{2.6034 \text{ ft}^3/\text{lbm}} (3.75/144 \text{ ft}^2) (1752 \text{ ft/s}) = \mathbf{17.53 \text{ lbm/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left( \frac{\Delta P}{\Delta(1/v)} \right)_s$$

The specific volume of steam at  $s_2 = 1.7173 \text{ Btu/lbm} \cdot \text{R}$  and at pressures just below and just above the specified pressure (250 and 300 psia) are determined to be 2.8036 and 2.4329  $\text{ft}^3/\text{lbm}$ . Substituting,

$$c_2 = \sqrt{\frac{(300 - 250) \text{ psia}}{\left( \frac{1}{2.4329} - \frac{1}{2.8036} \right) \text{ lbm/ft}^3} \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \left( \frac{1 \text{ Btu}}{5.4039 \text{ ft}^3 \cdot \text{psia}} \right)} = 2065 \text{ ft/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1752 \text{ ft/s}}{2065 \text{ ft/s}} = \mathbf{0.849}$$

**17-119** Steam enters a converging-diverging nozzle with a low velocity. The exit area and the exit Mach number are to be determined.

**Assumptions** Flow through the nozzle is steady, one-dimensional, and isentropic.

**Analysis** The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{01} = h_1$ .

At the inlet,

$$\left. \begin{aligned} P_1 &= P_{01} = 1 \text{ MPa} \\ T_1 &= T_{01} = 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &= h_{01} = 3479.1 \text{ kJ/kg} \\ s_1 &= s_{2s} = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At the exit,

$$\left. \begin{aligned} P_2 &= 0.2 \text{ MPa} \\ s_2 &= 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \begin{aligned} h_2 &= 3000.0 \text{ kJ/kg} \\ v_2 &= 1.2325 \text{ m}^3/\text{kg} \end{aligned}$$

Then the exit velocity is determined from the steady-flow energy balance  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  with  $q = w = 0$ ,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3479.1 - 3000.0) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 978.9 \text{ m/s}$$

The exit area is determined from

$$A_2 = \frac{\dot{m} v_2}{V_2} = \frac{(2.5 \text{ kg/s})(1.2325 \text{ m}^3/\text{kg})}{(978.9 \text{ m/s})} = 31.5 \times 10^{-4} \text{ m}^2 = \mathbf{31.5 \text{ cm}^2}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left( \frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at  $s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K}$  and at pressures just below and just above the specified pressure (0.1 and 0.3 MPa) are determined to be 2.0935 and 0.9024  $\text{m}^3/\text{kg}$ . Substituting,

$$c_2 = \sqrt{\frac{(300 - 100) \text{ kPa}}{\left( \frac{1}{0.9024} - \frac{1}{2.0935} \right) \text{ kg/m}^3} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 563.2 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{978.9 \text{ m/s}}{563.2 \text{ m/s}} = \mathbf{1.738}$$

**17-120** Steam enters a converging-diverging nozzle with a low velocity. The exit area and the exit Mach number are to be determined.

**Assumptions** Flow through the nozzle is steady and one-dimensional.

**Analysis** The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{01} = h_1$ .

$$\text{At the inlet, } \left. \begin{array}{l} P_1 = P_{01} = 1 \text{ MPa} \\ T_1 = T_{01} = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = h_{01} = 3479.1 \text{ kJ/kg} \\ s_1 = s_{2s} = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\text{At state } 2s, \left. \begin{array}{l} P_2 = 0.2 \text{ MPa} \\ s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 3000.0 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.95 = \frac{3479.1 - h_2}{3479.1 - 3000.0} \longrightarrow h_2 = 3023.9 \text{ kJ/kg}$$

Therefore,

$$\left. \begin{array}{l} P_2 = 0.2 \text{ MPa} \\ h_2 = 3023.9 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} v_2 = 1.2604 \text{ m}^3/\text{kg} \\ s_2 = 7.8083 \text{ kJ/kg} \cdot \text{K} \end{array}$$

Then the exit velocity is determined from the steady-flow energy balance  $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$  with  $q = w = 0$ ,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3479.1 - 3023.9) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 954.1 \text{ m/s}$$

The exit area is determined from

$$A_2 = \frac{\dot{m} v_2}{V_2} = \frac{(2.5 \text{ kg/s})(1.2604 \text{ m}^3/\text{kg})}{(954.1 \text{ m/s})} = 33.0 \times 10^{-4} \text{ m}^2 = \mathbf{33.1 \text{ cm}^2}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left( \frac{\Delta \mathcal{P}}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at  $s_2 = 7.8083 \text{ kJ/kg} \cdot \text{K}$  and at pressures just below and just above the specified pressure (0.1 and 0.3 MPa) are determined to be 2.1419 and 0.9225  $\text{m}^3/\text{kg}$ . Substituting,

$$c_2 = \sqrt{\frac{(300 - 100) \text{ kPa}}{\left( \frac{1}{0.9225} - \frac{1}{2.1419} \right) \text{ kg/m}^3} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 569.3 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{954.1 \text{ m/s}}{569.3 \text{ m/s}} = \mathbf{1.676}$$

## Review Problems

**17-121** A leak develops in an automobile tire as a result of an accident. The initial mass flow rate of air through the leak is to be determined.

**Assumptions** 1 Air is an ideal gas with constant specific heats. 2 Flow of air through the hole is isentropic.

**Properties** The gas constant of air is  $R = 0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K}$ . The specific heat ratio of air at room temperature is  $k = 1.4$  (Table A-2a).

**Analysis** The absolute pressure in the tire is

$$P = P_{\text{gage}} + P_{\text{atm}} = 220 + 94 = 314 \text{ kPa}$$

The critical pressure is, from Table 17-2,

$$P^* = 0.5283 P_0 = (0.5283)(314 \text{ kPa}) = 166 \text{ kPa} > 94 \text{ kPa}$$

Therefore, the flow is choked, and the velocity at the exit of the hole is the sonic speed. Then the flow properties at the exit becomes

$$\rho_0 = \frac{P_0}{RT_0} = \frac{314 \text{ kPa}}{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(298 \text{ K})} = 3.671 \text{ kg/m}^3$$

$$\rho^* = \rho_0 \left( \frac{2}{k+1} \right)^{1/(k-1)} = (3.671 \text{ kg/m}^3) \left( \frac{2}{1.4+1} \right)^{1/(1.4-1)} = 2.327 \text{ kg/m}^3$$

$$T^* = \frac{2}{k+1} T_0 = \frac{2}{1.4+1} (298 \text{ K}) = 248.3 \text{ K}$$

$$V = c = \sqrt{kRT^*} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K}) \left( \frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right) (248.3 \text{ K})} = 315.9 \text{ m/s}$$

Then the initial mass flow rate through the hole becomes

$$\dot{m} = \rho AV = (2.327 \text{ kg/m}^3) [\pi (0.004 \text{ m})^2 / 4] (315.9 \text{ m/s}) = 0.00924 \text{ kg/s} = \mathbf{0.554 \text{ kg/min}}$$

**Discussion** The mass flow rate will decrease with time as the pressure inside the tire drops.

**17-122** The thrust developed by the engine of a Boeing 777 is about 380 kN. The mass flow rate of air through the nozzle is to be determined.

**Assumptions** 1 Air is an ideal gas with constant specific properties. 2 Flow of combustion gases through the nozzle is isentropic. 3 Choked flow conditions exist at the nozzle exit. 4 The velocity of gases at the nozzle inlet is negligible.

**Properties** The gas constant of air is  $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$  (Table A-1), and it can also be used for combustion gases. The specific heat ratio of combustion gases is  $k = 1.33$  (Table 17-2).

**Analysis** The velocity at the nozzle exit is the sonic velocity, which is determined to be

$$V = c = \sqrt{kRT} = \sqrt{(1.33)(0.287 \text{ kJ/kg}\cdot\text{K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)(265 \text{ K})} = 318.0 \text{ m/s}$$

Noting that thrust  $F$  is related to velocity by  $F = \dot{m}V$ , the mass flow rate of combustion gases is determined to be

$$\dot{m} = \frac{F}{V} = \frac{380,000 \text{ N}}{318.0 \text{ m/s}} \left( \frac{1 \text{ kg}\cdot\text{m/s}^2}{1 \text{ N}} \right) = \mathbf{1194.8 \text{ kg/s}}$$

**Discussion** The combustion gases are mostly nitrogen (due to the 78% of  $\text{N}_2$  in air), and thus they can be treated as air with a good degree of approximation.

**17-123** A stationary temperature probe is inserted into an air duct reads  $85^\circ\text{C}$ . The actual temperature of air is to be determined.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 The stagnation process is isentropic.

**Properties** The specific heat of air at room temperature is  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The air that strikes the probe will be brought to a complete stop, and thus it will undergo a stagnation process. The thermometer will sense the temperature of this stagnated air, which is the stagnation temperature. The actual air temperature is determined from

$$T = T_0 - \frac{V^2}{2c_p} = 85^\circ\text{C} - \frac{(250 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{53.9^\circ\text{C}}$$

**Discussion** Temperature rise due to stagnation is very significant in high-speed flows, and should always be considered when compressibility effects are not negligible.

**17-124** Nitrogen flows through a heat exchanger. The stagnation pressure and temperature of the nitrogen at the inlet and the exit states are to be determined.

**Assumptions** 1 Nitrogen is an ideal gas with constant specific properties. 2 Flow of nitrogen through the heat exchanger is isentropic.

**Properties** The properties of nitrogen are  $c_p = 1.039$  kJ/kg·K and  $k = 1.4$  (Table A-2a).

**Analysis** The stagnation temperature and pressure of nitrogen at the inlet and the exit states are determined from

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 10^\circ\text{C} + \frac{(100 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg} \cdot ^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{14.8^\circ\text{C}}$$

$$P_{01} = P_1 \left( \frac{T_{01}}{T_1} \right)^{k/(k-1)} = (150 \text{ kPa}) \left( \frac{288.0 \text{ K}}{283.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{159.1 \text{ kPa}}$$

From the energy balance relation  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$  with  $w = 0$

$$q_{\text{in}} = c_p (T_2 - T_1) + \frac{V_2^2 - V_1^2}{2} + \Delta \text{pe} \approx 0$$

$$125 \text{ kJ/kg} = (1.039 \text{ kJ/kg} \cdot ^\circ\text{C})(T_2 - 10^\circ\text{C}) + \frac{(180 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$T_2 = 119.5^\circ\text{C}$$

and,

$$T_{02} = T_2 + \frac{V_2^2}{2c_p} = 119.5^\circ\text{C} + \frac{(180 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg} \cdot ^\circ\text{C}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{135.1^\circ\text{C}}$$

$$P_{02} = P_2 \left( \frac{T_{02}}{T_2} \right)^{k/(k-1)} = (100 \text{ kPa}) \left( \frac{408.3 \text{ K}}{392.7 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{114.6 \text{ kPa}}$$

**Discussion** Note that the stagnation temperature and pressure can be very different than their thermodynamic counterparts when dealing with compressible flow.

**17-125** An expression for the speed of sound based on van der Waals equation of state is to be derived. Using this relation, the speed of sound in carbon dioxide is to be determined and compared to that obtained by ideal gas behavior.

**Properties** The properties of CO<sub>2</sub> are  $R = 0.1889 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.279$  at  $T = 50^\circ\text{C} = 323.2 \text{ K}$  (Table A-2b).

**Analysis** Van der Waals equation of state can be expressed as

$$P = \frac{RT}{v-b} - \frac{a}{v^2}$$

Differentiating,

$$\left(\frac{\partial P}{\partial v}\right)_T = \frac{RT}{(v-b)^2} + \frac{2a}{v^3}$$

Noting that  $\rho = 1/v \longrightarrow d\rho = -dv/v^2$ , the speed of sound relation becomes

$$c^2 = k \left(\frac{\partial P}{\partial \rho}\right)_T = v^2 k \left(\frac{\partial P}{\partial v}\right)_T$$

Substituting,

$$c^2 = \frac{v^2 k RT}{(v-b)^2} - \frac{2ak}{v}$$

Using the molar mass of CO<sub>2</sub> ( $M = 44 \text{ kg/kmol}$ ), the constant  $a$  and  $b$  can be expressed per unit mass as

$$a = 0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2 \quad \text{and} \quad b = 9.70 \times 10^{-4} \text{ m}^3/\text{kg}$$

The specific volume of CO<sub>2</sub> is determined to be

$$200 \text{ kPa} = \frac{(0.1889 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(323.2 \text{ K})}{v - 0.000970 \text{ m}^3/\text{kg}} - \frac{2 \times 0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2}{v^2} \rightarrow v = 0.300 \text{ m}^3/\text{kg}$$

Substituting,

$$c = \left[ \frac{(0.300 \text{ m}^3/\text{kg})^2 (1.279)(0.1889 \text{ kJ/kg}\cdot\text{K})(323.2 \text{ K}) \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}}{(0.300 - 0.000970 \text{ m}^3/\text{kg})^2} - \frac{2(0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2)(1.279) \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa}\cdot\text{m}^3/\text{kg}}}{(0.300 \text{ m}^3/\text{kg})^2} \right]^{1/2} = 271 \text{ m/s}$$

If we treat CO<sub>2</sub> as an ideal gas, the speed of sound becomes

$$c = \sqrt{kRT} = \sqrt{(1.279)(0.1889 \text{ kJ/kg}\cdot\text{K})(323.2 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 279 \text{ m/s}$$

**Discussion** Note that the ideal gas relation is the simplest equation of state, and it is very accurate for most gases encountered in practice. At high pressures and/or low temperatures, however, the gases deviate from ideal gas behavior, and it becomes necessary to use more complicated equations of state.

**17-126** The equivalent relation for the speed of sound is to be verified using thermodynamic relations.

**Analysis** The two relations are  $c^2 = \left( \frac{\partial P}{\partial \rho} \right)_s$  and  $c^2 = k \left( \frac{\partial P}{\partial \rho} \right)_T$

From  $r = 1/\nu \longrightarrow dr = -d\nu/\nu^2$ . Thus,

$$c^2 = \left( \frac{\partial P}{\partial r} \right)_s = -\nu^2 \left( \frac{\partial P}{\partial \nu} \right)_s = -\nu^2 \left( \frac{\partial P}{\partial T} \frac{\partial T}{\partial \nu} \right)_s = -\nu^2 \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial T}{\partial \nu} \right)_s$$

From the cyclic rule,

$$(P, T, s) : \left( \frac{\partial P}{\partial T} \right)_s \left( \frac{\partial T}{\partial s} \right)_P \left( \frac{\partial s}{\partial P} \right)_T = -1 \longrightarrow \left( \frac{\partial P}{\partial T} \right)_s = - \left( \frac{\partial s}{\partial T} \right)_P \left( \frac{\partial P}{\partial s} \right)_T$$

$$(T, \nu, s) : \left( \frac{\partial T}{\partial \nu} \right)_s \left( \frac{\partial \nu}{\partial s} \right)_T \left( \frac{\partial s}{\partial T} \right)_\nu = -1 \longrightarrow \left( \frac{\partial T}{\partial \nu} \right)_s = - \left( \frac{\partial s}{\partial \nu} \right)_T \left( \frac{\partial T}{\partial s} \right)_\nu$$

Substituting,

$$c^2 = -\nu^2 \left( \frac{\partial s}{\partial T} \right)_P \left( \frac{\partial P}{\partial s} \right)_T \left( \frac{\partial s}{\partial \nu} \right)_T \left( \frac{\partial T}{\partial s} \right)_\nu = -\nu^2 \left( \frac{\partial s}{\partial T} \right)_P \left( \frac{\partial T}{\partial s} \right)_\nu \left( \frac{\partial P}{\partial s} \right)_T$$

Recall that

$$\frac{c_p}{T} = \left( \frac{\partial s}{\partial T} \right)_P \quad \text{and} \quad \frac{c_\nu}{T} = \left( \frac{\partial s}{\partial T} \right)_\nu$$

Substituting,

$$c^2 = -\nu^2 \left( \frac{c_p}{T} \right) \left( \frac{T}{c_\nu} \right) \left( \frac{\partial P}{\partial \nu} \right)_T = -\nu^2 k \left( \frac{\partial P}{\partial \nu} \right)_T$$

Replacing  $-d\nu/\nu^2$  by  $d\rho$ ,

$$c^2 = k \left( \frac{\partial P}{\partial \rho} \right)_T$$

**Discussion** Note that the differential thermodynamic property relations are very useful in the derivation of other property relations in differential form.

**17-127** For ideal gases undergoing isentropic flows, expressions for  $P/P^*$ ,  $T/T^*$ , and  $\rho/\rho^*$  as functions of  $k$  and  $Ma$  are to be obtained.

**Analysis** Equations 17-18 and 17-21 are given to be

$$\frac{T_0}{T} = \frac{2 + (k-1)Ma^2}{2}$$

and

$$\frac{T^*}{T_0} = \frac{2}{k+1}$$

Multiplying the two,

$$\left( \frac{T_0}{T} \frac{T^*}{T_0} \right) = \left( \frac{2 + (k-1)Ma^2}{2} \right) \left( \frac{2}{k+1} \right)$$

Simplifying and inverting,

$$\frac{T}{T^*} = \frac{k+1}{2 + (k-1)Ma^2} \quad (1)$$

From

$$\frac{P}{P^*} = \left( \frac{T}{T^*} \right)^{k/(k-1)} \longrightarrow \frac{P}{P^*} = \left( \frac{k+1}{2 + (k-1)Ma^2} \right)^{k/(k-1)} \quad (2)$$

From

$$\frac{\rho}{\rho^*} = \left( \frac{P}{P^*} \right)^{1/k} \longrightarrow \frac{\rho}{\rho^*} = \left( \frac{k+1}{2 + (k-1)Ma^2} \right)^{1/(k-1)} \quad (3)$$

**Discussion** Note that some very useful relations can be obtained by very simple manipulations.

**17-128** It is to be verified that for the steady flow of ideal gases  $dT_0/T = dA/A + (1-Ma^2) dV/V$ . The effect of heating and area changes on the velocity of an ideal gas in steady flow for subsonic flow and supersonic flow are to be explained.

**Analysis** We start with the relation  $\frac{V^2}{2} = c_p(T_0 - T)$ , (1)

Differentiating,  $V dV = c_p(dT_0 - dT)$  (2)

We also have  $\frac{d\rho}{\rho} + \frac{dA}{A} + \frac{dV}{V} = 0$  (3)

and  $\frac{dP}{\rho} + V dV = 0$  (4)

Differentiating the ideal gas relation  $P = \rho RT$ ,  $\frac{dP}{P} = \frac{d\rho}{\rho} + \frac{dT}{T} = 0$  (5)

From the speed of sound relation,  $c^2 = kRT = (k-1)c_p T = kP / \rho$  (6)

Combining Eqs. (3) and (5),  $\frac{dP}{P} - \frac{dT}{T} + \frac{dA}{A} + \frac{dV}{V} = 0$  (7)

Combining Eqs. (4) and (6),  $\frac{dP}{\rho} = \frac{dP}{kP / c^2} = -V dV$

or,  $\frac{dP}{P} = -\frac{k}{c^2} V dV = -k \frac{V^2}{c^2} \frac{dV}{V} = -k Ma^2 \frac{dV}{V}$  (8)

Combining Eqs. (2) and (6),  $dT = dT_0 - V \frac{dV}{c_p}$

or,  $\frac{dT}{T} = \frac{dT_0}{T} - \frac{V^2}{c_p T} \frac{dV}{V} = \frac{dT}{T} = \frac{dT_0}{T} - \frac{V^2}{c^2 / (k-1)} \frac{dV}{V} = \frac{dT_0}{T} - (k-1) Ma^2 \frac{dV}{V}$  (9)

Combining Eqs. (7), (8), and (9),  $-(k-1) Ma^2 \frac{dV}{V} - \frac{dT_0}{T} + (k-1) Ma^2 \frac{dV}{V} + \frac{dA}{A} + \frac{dV}{V} = 0$

or,  $\frac{dT_0}{T} = \frac{dA}{A} + [-k Ma^2 + (k-1) Ma^2 + 1] \frac{dV}{V}$

Thus,  $\frac{dT_0}{T} = \frac{dA}{A} + (1 - Ma^2) \frac{dV}{V}$  (10)

Differentiating the steady-flow energy equation  $q = h_{02} - h_{01} = c_p(T_{02} - T_{01})$

$\delta q = c_p dT_0$  (11)

Eq. (11) relates the stagnation temperature change  $dT_0$  to the net heat transferred to the fluid. Eq. (10) relates the velocity changes to area changes  $dA$ , and the stagnation temperature change  $dT_0$  or the heat transferred.

(a) When  $Ma < 1$  (subsonic flow), the fluid will accelerate if the duct converges ( $dA < 0$ ) or the fluid is heated ( $dT_0 > 0$  or  $\delta q > 0$ ). The fluid will decelerate if the duct converges ( $dA < 0$ ) or the fluid is cooled ( $dT_0 < 0$  or  $\delta q < 0$ ).

(b) When  $Ma > 1$  (supersonic flow), the fluid will accelerate if the duct diverges ( $dA > 0$ ) or the fluid is cooled ( $dT_0 < 0$  or  $\delta q < 0$ ). The fluid will decelerate if the duct converges ( $dA < 0$ ) or the fluid is heated ( $dT_0 > 0$  or  $\delta q > 0$ ).

**17-129** A pitot tube measures the difference between the static and stagnation pressures for a subsonic airplane. The speed of the airplane and the flight Mach number are to be determined.

**Assumptions** 1 Air is an ideal gas with constant specific heat ratio. 2 The stagnation process is isentropic.

**Properties** The properties of air are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The stagnation pressure of air at the specified conditions is

$$P_0 = P + \Delta P = 70.109 + 35 = 105.109 \text{ kPa}$$

Then,

$$\frac{P_0}{P} = \left( 1 + \frac{(k-1)\text{Ma}^2}{2} \right)^{k/(k-1)} \longrightarrow \frac{105.109}{70.109} = \left( 1 + \frac{(1.4-1)\text{Ma}^2}{2} \right)^{1.4/0.4}$$

It yields

$$\text{Ma} = \mathbf{0.783}$$

The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(268.65 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 328.5 \text{ m/s}$$

Thus,

$$V = \text{Ma} \times c = (0.783)(328.5 \text{ m/s}) = \mathbf{257.3 \text{ m/s}}$$

**Discussion** Note that the flow velocity can be measured in a simple and accurate way by simply measuring pressure.

**17-130** The mass flow parameter  $\dot{m}\sqrt{RT_0} / (AP_0)$  versus the Mach number for  $k = 1.2, 1.4$ , and  $1.6$  in the range of  $0 \leq \text{Ma} \leq 1$  is to be plotted.

**Analysis** The mass flow rate parameter  $(\dot{m}\sqrt{RT_0}) / P_0 A$  can be expressed as

$$\frac{\dot{m}\sqrt{RT_0}}{P_0 A} = \text{Ma} \sqrt{k} \left( \frac{2}{2 + (k-1)\text{Ma}^2} \right)^{(k+1)/2(k-1)}$$

Thus,

| Ma  | $k = 1.2$ | $k = 1.4$ | $k = 1.6$ |
|-----|-----------|-----------|-----------|
| 0.0 | 0         | 0         | 0         |
| 0.1 | 0.1089    | 0.1176    | 0.1257    |
| 0.2 | 0.2143    | 0.2311    | 0.2465    |
| 0.3 | 0.3128    | 0.3365    | 0.3582    |
| 0.4 | 0.4015    | 0.4306    | 0.4571    |
| 0.5 | 0.4782    | 0.5111    | 0.5407    |
| 0.6 | 0.5411    | 0.5763    | 0.6077    |
| 0.7 | 0.5894    | 0.6257    | 0.6578    |
| 0.8 | 0.6230    | 0.6595    | 0.6916    |
| 0.9 | 0.6424    | 0.6787    | 0.7106    |
| 1.0 | 0.6485    | 0.6847    | 0.7164    |

**Discussion** Note that the mass flow rate increases with increasing Mach number and specific heat ratio. It levels off at  $\text{Ma} = 1$ , and remains constant (choked flow).

**17-131** Helium gas is accelerated in a nozzle. The pressure and temperature of helium at the location where  $Ma = 1$  and the ratio of the flow area at this location to the inlet flow area are to be determined.

**Assumptions** 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of helium are  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.667$  (Table A-2a).

**Analysis** The properties of the fluid at the location where  $Ma = 1$  are the critical properties, denoted by superscript \*. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 500 \text{ K} + \frac{(120 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 501.4 \text{ K}$$

and

$$P_0 = P_i \left( \frac{T_0}{T_i} \right)^{k/(k-1)} = (0.8 \text{ MPa}) \left( \frac{501.4 \text{ K}}{500 \text{ K}} \right)^{1.667/(1.667-1)} = 0.806 \text{ MPa}$$

The Mach number at the nozzle exit is given to be  $Ma = 1$ . Therefore, the properties at the nozzle exit are the *critical properties* determined from

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (501.4 \text{ K}) \left( \frac{2}{1.667+1} \right) = 376 \text{ K}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (0.806 \text{ MPa}) \left( \frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.393 \text{ MPa}$$

The speed of sound and the Mach number at the nozzle inlet are

$$c_i = \sqrt{kRT_i} = \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(500 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1316 \text{ m/s}$$

$$Ma_i = \frac{V_i}{c_i} = \frac{120 \text{ m/s}}{1316 \text{ m/s}} = 0.0912$$

The ratio of the entrance-to-throat area is

$$\begin{aligned} \frac{A_i}{A^*} &= \frac{1}{Ma_i} \left[ \left( \frac{2}{k+1} \right) \left( 1 + \frac{k-1}{2} Ma_i^2 \right) \right]^{(k+1)/[2(k-1)]} \\ &= \frac{1}{0.0912} \left[ \left( \frac{2}{1.667+1} \right) \left( 1 + \frac{1.667-1}{2} (0.0912)^2 \right) \right]^{2.667/(2 \times 0.667)} \\ &= 6.20 \end{aligned}$$

Then the ratio of the throat area to the entrance area becomes

$$\frac{A^*}{A_i} = \frac{1}{6.20} = 0.161$$

**Discussion** The compressible flow functions are essential tools when determining the proper shape of the compressible flow duct.

**17-132** Helium gas enters a nozzle with negligible velocity, and is accelerated in a nozzle. The pressure and temperature of helium at the location where  $Ma = 1$  and the ratio of the flow area at this location to the inlet flow area are to be determined.

**Assumptions** **1** Helium is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic. **3** The entrance velocity is negligible.

**Properties** The properties of helium are  $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.667$  (Table A-2a).

**Analysis** We treat helium as an ideal gas with  $k = 1.667$ . The properties of the fluid at the location where  $Ma = 1$  are the critical properties, denoted by superscript  $*$ .

The stagnation temperature and pressure in this case are identical to the inlet temperature and pressure since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i = 500 \text{ K}$$

$$P_0 = P_i = 0.8 \text{ MPa}$$

The Mach number at the nozzle exit is given to be  $Ma = 1$ . Therefore, the properties at the nozzle exit are the *critical properties* determined from

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (500 \text{ K}) \left( \frac{2}{1.667+1} \right) = 375 \text{ K}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (0.8 \text{ MPa}) \left( \frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.390 \text{ MPa}$$

The ratio of the nozzle inlet area to the throat area is determined from

$$\frac{A_i}{A^*} = \frac{1}{Ma_i} \left[ \left( \frac{2}{k+1} \right) \left( 1 + \frac{k-1}{2} Ma_i^2 \right) \right]^{(k+1)/[2(k-1)]}$$

But the Mach number at the nozzle inlet is  $Ma = 0$  since  $V_i \cong 0$ . Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{\infty} = 0$$

**Discussion** The compressible flow functions are essential tools when determining the proper shape of the compressible flow duct.

**17-133 EES** Air enters a converging nozzle. The mass flow rate, the exit velocity, the exit Mach number, and the exit pressure-stagnation pressure ratio versus the back pressure-stagnation pressure ratio for a specified back pressure range are to be calculated and plotted.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

**Properties** The properties of air at room temperature are  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.4$  (Table A-2a).

**Analysis** The stagnation properties remain constant throughout the nozzle since the flow is isentropic. They are determined from

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 400 \text{ K} + \frac{(180 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 416.1 \text{ K}$$

and

$$P_0 = P_i \left( \frac{T_0}{T_i} \right)^{k/(k-1)} = (900 \text{ kPa}) \left( \frac{416.1 \text{ K}}{400 \text{ K}} \right)^{1.4/(1.4-1)} = 1033.3 \text{ kPa}$$

The critical pressure is determined to be

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (1033.3 \text{ kPa}) \left( \frac{2}{1.4+1} \right)^{1.4/0.4} = 545.9 \text{ kPa}$$

Then the pressure at the exit plane (throat) will be

$$\begin{aligned} P_e &= P_b & \text{for } P_b \geq 545.9 \text{ kPa} \\ P_e &= P^* = 545.9 \text{ kPa} & \text{for } P_b < 545.9 \text{ kPa} \quad (\text{choked flow}) \end{aligned}$$

Thus the back pressure will not affect the flow when  $100 < P_b < 545.9 \text{ kPa}$ . For a specified exit pressure  $P_e$ , the temperature, the velocity and the mass flow rate can be determined from

$$\text{Temperature} \quad T_e = T_0 \left( \frac{P_e}{P_0} \right)^{(k-1)/k} = (416.1 \text{ K}) \left( \frac{P_e}{1033.3} \right)^{0.4/1.4}$$

$$\text{Velocity} \quad V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.005 \text{ kJ/kg}\cdot\text{K})(416.1 - T_e) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Speed of sound} \quad c_e = \sqrt{kRT_e} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Mach number} \quad \text{Ma}_e = V_e / c_e$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.001 \text{ m}^2)$$

The results of the calculations can be tabulated as

| $P_b$ , kPa | $P_b, P_0$ | $P_e$ , kPa | $P_b, P_0$ | $T_e$ , K | $V_e$ , m/s | Ma   | $\rho_e$ , kg/m <sup>3</sup> | $\dot{m}$ , kg / s |
|-------------|------------|-------------|------------|-----------|-------------|------|------------------------------|--------------------|

| 100         | 0.097      | 545.9       | 0.528      | 333.3     | 366.2       | 1.00 | 4.971                        | 1.820              |

**17-134 EES** Steam enters a converging nozzle. The exit pressure, the exit velocity, and the mass flow rate versus the back pressure for a specified back pressure range are to be plotted.

**Assumptions** 1 Steam is to be treated as an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

**Properties** The ideal gas properties of steam are given to be  $R = 0.462 \text{ kJ/kg}\cdot\text{K}$ ,  $c_p = 1.872 \text{ kJ/kg}\cdot\text{K}$ , and  $k = 1.3$ .

**Analysis** The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Since the flow is isentropic, they remain constant throughout the nozzle,

$$P_0 = P_i = 6 \text{ MPa}$$

$$T_0 = T_i = 700 \text{ K}$$

The critical pressure is determined from to be

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (6 \text{ MPa}) \left( \frac{2}{1.3+1} \right)^{1.3/0.3} = 3.274 \text{ MPa}$$

Then the pressure at the exit plane (throat) will be

$$P_e = P_b \quad \text{for} \quad P_b \geq 3.274 \text{ MPa}$$

$$P_e = P^* = 3.274 \text{ MPa} \quad \text{for} \quad P_b < 3.274 \text{ MPa} \quad (\text{choked flow})$$

Thus the back pressure will not affect the flow when  $3 < P_b < 3.274 \text{ MPa}$ . For a specified exit pressure  $P_e$ , the temperature, the velocity and the mass flow rate can be determined from

Temperature

$$T_e = T_0 \left( \frac{P_e}{P_0} \right)^{(k-1)/k} = (700 \text{ K}) \left( \frac{P_e}{6} \right)^{0.3/1.3}$$

Velocity

$$V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.872 \text{ kJ/kg}\cdot\text{K})(700 - T_e) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

Density

$$\rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.462 \text{ kPa}\cdot\text{m}^3 / \text{kg}\cdot\text{K})T_e}$$

Mass flow rate

$$\dot{m} = \rho_e V_e A_e = \rho_e V_e (0.0008 \text{ m}^2)$$

The results of the calculations can be tabulated as follows:

| $P_b$ , MPa | $P_e$ , MPa | $T_e$ , K | $V_e$ , m/s | $\rho_e$ , kg/m <sup>3</sup> | $\dot{m}$ , kg/s |
|-------------|-------------|-----------|-------------|------------------------------|------------------|
| 6.0         | 6.0         | 700       | 0           | 18.55                        | 0                |
| 5.5         | 5.5         | 686.1     | 228.1       | 17.35                        | 3.166            |
| 5.0         | 5.0         | 671.2     | 328.4       | 16.12                        | 4.235            |
| 4.5         | 4.5         | 655.0     | 410.5       | 14.87                        | 4.883            |
| 4.0         | 4.0         | 637.5     | 483.7       | 13.58                        | 5.255            |
| 3.5         | 3.5         | 618.1     | 553.7       | 12.26                        | 5.431            |
| 3.274       | 3.274       | 608.7     | 584.7       | 11.64                        | 5.445            |
| 3.0         | 3.274       | 608.7     | 584.7       | 11.64                        | 5.445            |

**17-135** An expression for the ratio of the stagnation pressure after a shock wave to the static pressure before the shock wave as a function of  $k$  and the Mach number upstream of the shock wave is to be found.

**Analysis** The relation between  $P_1$  and  $P_2$  is

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_2^2}{1 + k\text{Ma}_1^2} \longrightarrow P_2 = P_1 \left( \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right)$$

Substituting this into the isentropic relation

$$\frac{P_{02}}{P_1} = \left( 1 + (k-1)\text{Ma}_2^2 / 2 \right)^{k/(k-1)}$$

Then,

$$\frac{P_{02}}{P_1} = \left( \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right) \left( 1 + (k-1)\text{Ma}_2^2 / 2 \right)^{k/(k-1)}$$

where

$$\text{Ma}_2^2 = \frac{\text{Ma}_1^2 + 2/(k-1)}{2k\text{Ma}_1^2/(k-1) - 1}$$

Substituting,

$$\frac{P_{02}}{P_1} = \left( \frac{(1 + k\text{Ma}_1^2)(2k\text{Ma}_1^2 - k + 1)}{k\text{Ma}_1^2(k+1) - k + 3} \right) \left( 1 + \frac{(k-1)\text{Ma}_1^2 / 2 + 1}{2k\text{Ma}_1^2/(k-1) - 1} \right)^{k/(k-1)}$$

**17-136** Nitrogen entering a converging-diverging nozzle experiences a normal shock. The pressure, temperature, velocity, Mach number, and stagnation pressure downstream of the shock are to be determined. The results are to be compared to those of air under the same conditions.

**Assumptions** 1 Nitrogen is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

**Properties** The properties of nitrogen are  $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$  and  $k = 1.4$  (Table A-2a).

**Analysis** The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Assuming the flow before the shock to be isentropic,

$$P_{01} = P_i = 700 \text{ kPa}$$

$$T_{01} = T_i = 300 \text{ K}$$

Then,

$$T_1 = T_{01} \left( \frac{2}{2 + (k-1)\text{Ma}_1^2} \right) = (300 \text{ K}) \left( \frac{2}{2 + (1.4-1)3^2} \right) = 107.1 \text{ K}$$

and

$$P_1 = P_{01} \left( \frac{T_1}{T_{01}} \right)^{k/(k-1)} = (700 \text{ kPa}) \left( \frac{107.1}{300} \right)^{1.4/0.4} = 19.06 \text{ kPa}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-14. For  $\text{Ma}_1 = 3.0$  we read

$$\text{Ma}_2 = \mathbf{0.4752}, \quad \frac{P_{02}}{P_{01}} = 0.32834, \quad \frac{P_2}{P_1} = 10.333, \quad \text{and} \quad \frac{T_2}{T_1} = 2.679$$

Then the stagnation pressure  $P_{02}$ , static pressure  $P_2$ , and static temperature  $T_2$ , are determined to be

$$P_{02} = 0.32834 P_{01} = (0.32834)(700 \text{ kPa}) = \mathbf{230 \text{ kPa}}$$

$$P_2 = 10.333 P_1 = (10.333)(19.06 \text{ kPa}) = \mathbf{197 \text{ kPa}}$$

$$T_2 = 2.679 T_1 = (2.679)(107.1 \text{ K}) = \mathbf{287 \text{ K}}$$

The velocity after the shock can be determined from  $V_2 = \text{Ma}_2 c_2$ , where  $c_2$  is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.4752) \sqrt{(1.4)(0.2968 \text{ kJ/kg}\cdot\text{K})(287 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{164 \text{ m/s}}$$

**Discussion** For **air** at specified conditions  $k = 1.4$  (same as nitrogen) and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ . Thus the only quantity which will be different in the case of air is the velocity after the normal shock, which happens to be  $161.3 \text{ m/s}$ .

**17-137** The diffuser of an aircraft is considered. The static pressure rise across the diffuser and the exit area are to be determined.

**Assumptions** 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the diffuser is steady, one-dimensional, and isentropic. 3 The diffuser is adiabatic.

**Properties** Air properties at room temperature are  $R = 0.287$  kJ/kg·K,  $c_p = 1.005$  kJ/kg·K, and  $k = 1.4$  (Table A-2a).

**Analysis** The inlet velocity is

$$V_1 = Ma_1 c_1 = Ma_1 \sqrt{kRT_1} = (0.8) \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(242.7 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 249.8 \text{ m/s}$$

Then the stagnation temperature and pressure at the diffuser inlet become

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 242.7 + \frac{(249.8 \text{ m/s})^2}{2(1.005 \text{ kJ/kg} \cdot \text{K}) \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)} = 273.7 \text{ K}$$

$$P_{01} = P_1 \left( \frac{T_{01}}{T_1} \right)^{k/(k-1)} = (41.1 \text{ kPa}) \left( \frac{273.7 \text{ K}}{242.7 \text{ K}} \right)^{1.4/(1.4-1)} = 62.6 \text{ kPa}$$

For an adiabatic diffuser, the energy equation reduces to  $h_{01} = h_{02}$ . Noting that  $h = c_p T$  and the specific heats are assumed to be constant, we have

$$T_{01} = T_{02} = T_0 = 273.7 \text{ K}$$

The isentropic relation between states 1 and 02 gives

$$P_{02} = P_{01} = P_1 \left( \frac{T_{02}}{T_1} \right)^{k/(k-1)} = (41.1 \text{ kPa}) \left( \frac{273.72 \text{ K}}{242.7 \text{ K}} \right)^{1.4/(1.4-1)} = 62.61 \text{ kPa}$$

The exit velocity can be expressed as

$$V_2 = Ma_2 c_2 = Ma_2 \sqrt{kRT_2} = (0.3) \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K}) T_2 \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 6.01 \sqrt{T_2}$$

$$\text{Thus, } T_2 = T_{02} - \frac{V_2^2}{2c_p} = (273.7) - \frac{6.01^2 T_2 \text{ m}^2/\text{s}^2}{2(1.005 \text{ kJ/kg} \cdot \text{K}) \left( \frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)} = 268.9 \text{ K}$$

Then the static exit pressure becomes

$$P_2 = P_{02} \left( \frac{T_2}{T_{02}} \right)^{k/(k-1)} = (62.61 \text{ kPa}) \left( \frac{268.9 \text{ K}}{273.7 \text{ K}} \right)^{1.4/(1.4-1)} = 58.85 \text{ kPa}$$

Thus the static pressure rise across the diffuser is

$$\Delta P = P_2 - P_1 = 58.85 - 41.1 = \mathbf{17.8 \text{ kPa}}$$

$$\text{Also, } \rho_2 = \frac{P_2}{RT_2} = \frac{58.85 \text{ kPa}}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(268.9 \text{ K})} = 0.7626 \text{ kg/m}^3$$

$$V_2 = 6.01 \sqrt{T_2} = 6.01 \sqrt{268.9} = 98.6 \text{ m/s}$$

$$\text{Thus } A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{65 \text{ kg/s}}{(0.7626 \text{ kg/m}^3)(98.6 \text{ m/s})} = \mathbf{0.864 \text{ m}^2}$$

**Discussion** The pressure rise in actual diffusers will be lower because of the irreversibilities. However, flow through well-designed diffusers is very nearly isentropic.

**17-138** Helium gas is accelerated in a nozzle isentropically. For a specified mass flow rate, the throat and exit areas of the nozzle are to be determined.

**Assumptions** 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

**Properties** The properties of helium are  $R = 2.0769 \text{ kJ/kg} \cdot \text{K}$ ,  $c_p = 5.1926 \text{ kJ/kg} \cdot \text{K}$ ,  $k = 1.667$  (Table A-2a).

**Analysis** The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible,

$$T_{01} = T_1 = 500 \text{ K}$$

$$P_{01} = P_1 = 1.0 \text{ MPa}$$

The flow is assumed to be isentropic, thus the stagnation temperature and pressure remain constant throughout the nozzle,

$$T_{02} = T_{01} = 500 \text{ K}$$

$$P_{02} = P_{01} = 1.0 \text{ MPa}$$

The critical pressure and temperature are determined from

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (500 \text{ K}) \left( \frac{2}{1.667+1} \right) = 375.0 \text{ K}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (1.0 \text{ MPa}) \left( \frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.487 \text{ MPa}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{487 \text{ kPa}}{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(375 \text{ K})} = 0.625 \text{ kg/m}^3$$

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.667)(2.0769 \text{ kJ/kg} \cdot \text{K})(375 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1139.4 \text{ m/s}$$

Thus the throat area is

$$A^* = \frac{\dot{m}}{\rho^* V^*} = \frac{0.25 \text{ kg/s}}{(0.625 \text{ kg/m}^3)(1139.4 \text{ m/s})} = 3.51 \times 10^{-4} \text{ m}^2 = \mathbf{3.51 \text{ cm}^2}$$

At the nozzle exit the pressure is  $P_2 = 0.1 \text{ MPa}$ . Then the other properties at the nozzle exit are determined to be

$$\frac{P_0}{P_2} = \left( 1 + \frac{k-1}{2} \text{Ma}_2^2 \right)^{k/(k-1)} \longrightarrow \frac{1.0 \text{ MPa}}{0.1 \text{ MPa}} = \left( 1 + \frac{1.667-1}{2} \text{Ma}_2^2 \right)^{1.667/0.667}$$

It yields  $\text{Ma}_2 = 2.130$ , which is greater than 1. Therefore, the nozzle must be converging-diverging.

$$T_2 = T_0 \left( \frac{2}{2 + (k-1)\text{Ma}_2^2} \right) = (500 \text{ K}) \left( \frac{2}{2 + (1.667-1) \times 2.13^2} \right) = 199.0 \text{ K}$$

$$\rho_2 = \frac{P_2}{RT_2} = \frac{100 \text{ kPa}}{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(199 \text{ K})} = 0.242 \text{ kg/m}^3$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (2.13) \sqrt{(1.667)(2.0769 \text{ kJ/kg} \cdot \text{K})(199 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1768.0 \text{ m/s}$$

Thus the exit area is

$$A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{0.25 \text{ kg/s}}{(0.242 \text{ kg/m}^3)(1768 \text{ m/s})} = 5.84 \times 10^{-4} \text{ m}^2 = \mathbf{5.84 \text{ cm}^2}$$

**Discussion** Flow areas in actual nozzles would be somewhat larger to accommodate the irreversibilities.

**17-139E** Helium gas is accelerated in a nozzle. For a specified mass flow rate, the throat and exit areas of the nozzle are to be determined for the cases of isentropic and 97% efficient nozzles.

**Assumptions** 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

**Properties** The properties of helium are  $R = 0.4961 \text{ Btu/lbm} \cdot \text{R} = 2.6809 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ ,  $c_p = 1.25 \text{ Btu/lbm} \cdot \text{R}$ , and  $k = 1.667$  (Table A-2Ea).

**Analysis** The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible,

$$T_{01} = T_1 = 900 \text{ R}$$

$$P_{01} = P_1 = 150 \text{ psia}$$

The flow is assumed to be isentropic, thus the stagnation temperature and pressure remain constant throughout the nozzle,

$$T_{02} = T_{01} = 900 \text{ R}$$

$$P_{02} = P_{01} = 150 \text{ psia}$$

The critical pressure and temperature are determined from

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (900 \text{ R}) \left( \frac{2}{1.667+1} \right) = 674.9 \text{ R}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (150 \text{ psia}) \left( \frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 73.1 \text{ psia}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{73.1 \text{ psia}}{(2.6809 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(674.9 \text{ R})} = 0.0404 \text{ lbm/ft}^3$$

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.667)(0.4961 \text{ Btu/lbm} \cdot \text{R})(674.9 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 3738 \text{ ft/s}$$

and 
$$A^* = \frac{\dot{m}}{\rho^* V^*} = \frac{0.2 \text{ lbm/s}}{(0.0404 \text{ lbm/ft}^3)(3738 \text{ ft/s})} = \mathbf{0.00132 \text{ ft}^2}$$

At the nozzle exit the pressure is  $P_2 = 15 \text{ psia}$ . Then the other properties at the nozzle exit are determined to be

$$\frac{P_0}{P_2} = \left( 1 + \frac{k-1}{2} \text{Ma}_2^2 \right)^{k/(k-1)} \longrightarrow \frac{150 \text{ psia}}{15 \text{ psia}} = \left( 1 + \frac{1.667-1}{2} \text{Ma}_2^2 \right)^{1.667/0.667}$$

It yields  $\text{Ma}_2 = 2.130$ , which is greater than 1. Therefore, the nozzle must be converging-diverging.

$$T_2 = T_0 \left( \frac{2}{2 + (k-1)\text{Ma}_2^2} \right) = (900 \text{ R}) \left( \frac{2}{2 + (1.667-1) \times 2.13^2} \right) = 358.1 \text{ R}$$

$$\rho_2 = \frac{P_2}{RT_2} = \frac{15 \text{ psia}}{(2.6809 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(358.1 \text{ R})} = 0.0156 \text{ lbm/ft}^3$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (2.13) \sqrt{(1.667)(0.4961 \text{ Btu/lbm} \cdot \text{R})(358.1 \text{ R}) \left( \frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 5800 \text{ ft/s}$$

Thus the exit area is

$$A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{0.2 \text{ lbm/s}}{(0.0156 \text{ lbm/ft}^3)(5800 \text{ ft/s})} = \mathbf{0.00221 \text{ ft}^2}$$

**Discussion** Flow areas in actual nozzles would be somewhat larger to accommodate the irreversibilities.

**17-140** [Also solved by EES on enclosed CD] Using the compressible flow relations, the one-dimensional compressible flow functions are to be evaluated and tabulated as in Table A-32 for an ideal gas with  $k = 1.667$ .

**Properties** The specific heat ratio of the ideal gas is given to be  $k = 1.667$ .

**Analysis** The compressible flow functions listed below are expressed in EES and the results are tabulated.

$$\begin{aligned} \text{Ma}^* &= \text{Ma} \sqrt{\frac{k+1}{2+(k-1)\text{Ma}^2}} \\ \frac{A}{A^*} &= \frac{1}{\text{Ma}} \left[ \left( \frac{2}{k+1} \right) \left( 1 + \frac{k-1}{2} \text{Ma}^2 \right) \right]^{0.5(k+1)/(k-1)} \\ \frac{P}{P_0} &= \left( 1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-k/(k-1)} \\ \frac{\rho}{\rho_0} &= \left( 1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1/(k-1)} \\ \frac{T}{T_0} &= \left( 1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1} \end{aligned}$$

$k=1.667$

$\text{PP0}=(1+(k-1)*\text{Ma}^2/2)^{-k/(k-1)}$

$\text{TT0}=1/(1+(k-1)*\text{Ma}^2/2)$

**17-142** The critical temperature, pressure, and density of an equimolar mixture of oxygen and nitrogen for specified stagnation properties are to be determined.

**Assumptions** Both oxygen and nitrogen are ideal gases with constant specific heats at room temperature.

**Properties** The specific heat ratio and molar mass are  $k = 1.395$  and  $M = 32$  kg/kmol for oxygen, and  $k = 1.4$  and  $M = 28$  kg/kmol for nitrogen (Tables A-1 and A-2).

**Analysis** The gas constant of the mixture is

$$M_m = y_{O_2} M_{O_2} + y_{N_2} M_{N_2} = 0.5 \times 32 + 0.5 \times 28 = 30 \text{ kg/kmol}$$

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{30 \text{ kg/kmol}} = 0.2771 \text{ kJ/kg} \cdot \text{K}$$

The specific heat ratio is 1.4 for nitrogen, and nearly 1.4 for oxygen. Therefore, the specific heat ratio of the mixture is also 1.4. Then the critical temperature, pressure, and density of the mixture become

$$T^* = T_0 \left( \frac{2}{k+1} \right) = (800 \text{ K}) \left( \frac{2}{1.4+1} \right) = \mathbf{667 \text{ K}}$$

$$P^* = P_0 \left( \frac{2}{k+1} \right)^{k/(k-1)} = (500 \text{ kPa}) \left( \frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{264 \text{ kPa}}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{264 \text{ kPa}}{(0.2771 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(667 \text{ K})} = \mathbf{1.43 \text{ kg/m}^3}$$

**Discussion** If the specific heat ratios  $k$  of the two gases were different, then we would need to determine the  $k$  of the mixture from  $k = c_{p,m}/c_{v,m}$  where the specific heats of the mixture are determined from

$$c_{p,m} = mf_{O_2} c_{p,O_2} + mf_{N_2} c_{p,N_2} = (y_{O_2} M_{O_2} / M_m) c_{p,O_2} + (y_{N_2} M_{N_2} / M_m) c_{p,N_2}$$

$$c_{v,m} = mf_{O_2} c_{v,O_2} + mf_{N_2} c_{v,N_2} = (y_{O_2} M_{O_2} / M_m) c_{v,O_2} + (y_{N_2} M_{N_2} / M_m) c_{v,N_2}$$

where  $mf$  is the mass fraction and  $y$  is the mole fraction. In this case it would give

$$c_{p,m} = (0.5 \times 32 / 30) \times 0.918 + (0.5 \times 28 / 30) \times 1.039 = 0.974 \text{ kJ/kg} \cdot \text{K}$$

$$c_{v,m} = (0.5 \times 32 / 30) \times 0.658 + (0.5 \times 28 / 30) \times 0.743 = 0.698 \text{ kJ/kg} \cdot \text{K}$$

and

$$k = 0.974 / 0.698 = 1.40$$

**17-143 EES** Using EES (or other) software, the shape of a converging-diverging nozzle is to be determined for specified flow rate and stagnation conditions. The nozzle and the Mach number are to be plotted.

**Assumptions** **1** Air is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic. **3** The nozzle is adiabatic.

**Properties** The specific heat ratio of air at room temperature is 1.4 (Table A-2a).

**Analysis** The problem is solved using EES, and the results are tabulated and plotted below.

```

k=1.4
Cp=1.005 "kJ/kg.K"
R=0.287 "kJ/kg.K"
P0=1400 "kPa"
T0=200+273 "K"
m=3 "kg/s"
rho_0=P0/(R*T0)
rho=P/(R*T)
T=T0*(P/P0)^((k-1)/k)
V=SQRT(2*Cp*(T0-T)*1000)
A=m/(rho*V)*10000 "cm2"
C=SQRT(k*R*T*1000)
Ma=V/C

**17-148** Air flowing at a supersonic velocity in a duct is accelerated by cooling. For a specified exit Mach number, the rate of heat transfer is to be determined.

**Assumptions** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Knowing stagnation properties, the static properties are determined to be

$$T_1 = T_{01} \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-1} = (350 \text{ K}) \left( 1 + \frac{1.4-1}{2} 1.2^2 \right)^{-1} = 271.7 \text{ K}$$

$$P_1 = P_{01} \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-k/(k-1)} = (240 \text{ kPa}) \left( 1 + \frac{1.4-1}{2} 1.2^2 \right)^{-1.4/0.4} = 98.97 \text{ kPa}$$

$$\rho_1 = \frac{P_1}{RT_1} = \frac{98.97 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(271.7 \text{ K})} = 1.269 \text{ kg/m}^3$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(271.7 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 330.4 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 1.2(330.4 \text{ m/s}) = 396.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (1.269 \text{ kg/m}^3) [\pi (0.20 \text{ m})^2 / 4] (396.5 \text{ m/s}) = 15.81 \text{ kg/s}$$

The Rayleigh flow functions  $T_0/T_0^*$  corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1.2: \quad T_{01}/T_0^* = 0.9787$$

$$\text{Ma}_2 = 2: \quad T_{02}/T_0^* = 0.7934$$

Then the exit stagnation temperature is determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{0.7934}{0.9787} = 0.8107 \quad \rightarrow \quad T_{02} = 0.8107 T_{01} = 0.8107(350 \text{ K}) = 283.7 \text{ K}$$

Finally, the rate of heat transfer is

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (15.81 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(283.7 - 350) \text{ K} = \mathbf{-1053 \text{ kW}}$$

**Discussion** The negative sign confirms that the gas needs to be cooled in order to be accelerated. Also, it can be shown that the thermodynamic temperature drops to 158 K at the exit, which is extremely low. Therefore, the duct may need to be heavily insulated to maintain indicated flow conditions.

**17-149** Air flowing at a subsonic velocity in a duct is accelerated by heating. The highest rate of heat transfer without affecting the inlet conditions is to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Inlet conditions (and thus the mass flow rate) remain constant.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Heat transfer will stop when the flow is choked, and thus  $\text{Ma}_2 = V_2/c_2 = 1$ . The inlet density and stagnation temperature are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{400 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(360 \text{ K})} = 3.872 \text{ kg/m}^3$$

$$T_{01} = T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (360 \text{ K}) \left( 1 + \frac{1.4-1}{2} 0.4^2 \right) = 371.5 \text{ K}$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(360 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 380.3 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 0.4(380.3 \text{ m/s}) = 152.1 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (3.872 \text{ kg/m}^3)(0.1 \times 0.1 \text{ m}^2)(152.1 \text{ m/s}) = 5.890 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \quad (\text{since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.4+1)0.4^2 [2 + (1.4-1)0.4^2]}{(1+1.4 \times 0.4^2)^2} = 0.5290$$

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.5290} \quad \rightarrow \quad T_{02} = T_{01} / 0.5290 = (371.5 \text{ K}) / 0.5290 = 702.3 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (5.890 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(702.3 - 371.5) \text{ K} = \mathbf{1958 \text{ kW}}$$

**Discussion** It can also be shown that  $T_2 = 585 \text{ K}$ , which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. We can also solve this problem using the Rayleigh function values listed in Table A-34.

**17-150** Helium flowing at a subsonic velocity in a duct is accelerated by heating. The highest rate of heat transfer without affecting the inlet conditions is to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Inlet conditions (and thus the mass flow rate) remain constant.

**Properties** We take the properties of helium to be  $k = 1.667$ ,  $c_p = 5.193 \text{ kJ/kg} \cdot \text{K}$ , and  $R = 2.077 \text{ kJ/kg} \cdot \text{K}$  (Table A-2a).

**Analysis** Heat transfer will stop when the flow is choked, and thus  $\text{Ma}_2 = V_2/c_2 = 1$ . The inlet density and stagnation temperature are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{400 \text{ kPa}}{(2.077 \text{ kJ/kg} \cdot \text{K})(360 \text{ K})} = 0.5350 \text{ kg/m}^3$$

$$T_{01} = T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (360 \text{ K}) \left( 1 + \frac{1.667-1}{2} 0.4^2 \right) = 379.2 \text{ K}$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.667)(2.077 \text{ kJ/kg} \cdot \text{K})(360 \text{ K}) \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1116 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 0.4(1116 \text{ m/s}) = 446.6 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (0.5350 \text{ kg/m}^3)(0.1 \times 0.1 \text{ m}^2)(446.6 \text{ m/s}) = 2.389 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \quad (\text{since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.667+1)0.4^2 [2 + (1.667-1)0.4^2]}{(1+1.667 \times 0.4^2)^2} = 0.5603$$

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.5603} \quad \rightarrow \quad T_{02} = T_{01} / 0.5603 = (379.2 \text{ K}) / 0.5603 = 676.8 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (2.389 \text{ kg/s})(5.193 \text{ kJ/kg} \cdot \text{K})(676.8 - 379.2) \text{ K} = \mathbf{3693 \text{ kW}}$$

**Discussion** It can also be shown that  $T_2 = 508 \text{ K}$ , which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. Also, in the solution of this problem, we cannot use the values of Table A-34 since they are based on  $k = 1.4$ .

**17-151** Air flowing at a subsonic velocity in a duct is accelerated by heating. For a specified exit Mach number, the heat transfer for a specified exit Mach number as well as the maximum heat transfer are to be determined.

**Assumptions 1** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Inlet conditions (and thus the mass flow rate) remain constant.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** The inlet Mach number and stagnation temperature are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(400 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 400.9 \text{ m/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{100 \text{ m/s}}{400.9 \text{ m/s}} = 0.2494$$

$$\begin{aligned} T_{01} &= T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) \\ &= (400 \text{ K}) \left( 1 + \frac{1.4-1}{2} (0.2494)^2 \right) \\ &= 405.0 \text{ K} \end{aligned}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.2494: \quad T_{01}/T^* = 0.2559$$

$$\text{Ma}_2 = 0.8: \quad T_{02}/T^* = 0.9639$$

Then the exit stagnation temperature and the heat transfer are determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{0.9639}{0.2559} = 3.7667 \rightarrow T_{02} = 3.7667 T_{01} = 3.7667(405.0 \text{ K}) = 1526 \text{ K}$$

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(1526 - 405) \text{ K} = \mathbf{1126 \text{ kJ/kg}}$$

Maximum heat transfer will occur when the flow is choked, and thus  $\text{Ma}_2 = 1$  and thus  $T_{02}/T^* = 1$ . Then,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{1}{0.2559} \rightarrow T_{02} = T_{01} / 0.2559 = (405.0 \text{ K}) / 0.2559 = 1583 \text{ K}$$

$$q_{\max} = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(1583 - 405) \text{ K} = \mathbf{1184 \text{ kJ/kg}}$$

**Discussion** This is the maximum heat that can be transferred to the gas without affecting the mass flow rate. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease.

**17-152** Air flowing at sonic conditions in a duct is accelerated by cooling. For a specified exit Mach number, the amount of heat transfer per unit mass is to be determined.

**Assumptions** The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

**Properties** We take the properties of air to be  $k = 1.4$ ,  $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ , and  $R = 0.287 \text{ kJ/kg}\cdot\text{K}$  (Table A-2a).

**Analysis** Noting that  $\text{Ma}_1 = 1$ , the inlet stagnation temperature is

$$\begin{aligned} T_{01} &= T_1 \left( 1 + \frac{k-1}{2} \text{Ma}_1^2 \right) \\ &= (500 \text{ K}) \left( 1 + \frac{1.4-1}{2} 1^2 \right) = 600 \text{ K} \end{aligned}$$

The Rayleigh flow functions  $T_0/T_0^*$  corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\begin{aligned} \text{Ma}_1 = 1: \quad T_{01}/T_0^* &= 1 \\ \text{Ma}_2 = 1.6: \quad T_{02}/T_0^* &= 0.8842 \end{aligned}$$

Then the exit stagnation temperature and heat transfer are determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{0.8842}{1} = 0.8842 \quad \rightarrow \quad T_{02} = 0.8842 T_{01} = 0.8842(600 \text{ K}) = 530.5 \text{ K}$$

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(530.5 - 600) \text{ K} = \mathbf{-69.8 \text{ kJ/kg}}$$

**Discussion** The negative sign confirms that the gas needs to be cooled in order to be accelerated. Also, it can be shown that the thermodynamic temperature drops to 351 K at the exit

**17-153** Saturated steam enters a converging-diverging nozzle with a low velocity. The throat area, exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

**Assumptions** 1 Flow through the nozzle is steady and one-dimensional. 2 The nozzle is adiabatic.

**Analysis** (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{10} = h_1$ . At the inlet,

$$h_1 = (h_f + x_1 h_{fg})_{@3 \text{ MPa}} = 1008.3 + 0.95 \times 1794.9 = 2713.4 \text{ kJ/kg}$$

$$s_1 = (s_f + x_1 s_{fg})_{@3 \text{ MPa}} = 2.6454 + 0.95 \times 3.5402 = 6.0086 \text{ kJ/kg} \cdot \text{K}$$

At the exit,  $P_2 = 1.2 \text{ MPa}$  and  $s_2 = s_{2s} = s_1 = 6.0086 \text{ kJ/kg} \cdot \text{K}$ . Thus,

$$s_2 = s_f + x_2 s_{fg} \rightarrow 6.0086 = 2.2159 + x_2 (4.3058) \rightarrow x_2 = 0.8808$$

$$h_2 = h_f + x_2 h_{fg} = 798.33 + 0.8808 \times 1985.4 = 2547.2 \text{ kJ/kg}$$

$$\nu_2 = \nu_f + x_2 \nu_{fg} = 0.001138 + 0.8808 \times (0.16326 - 0.001138) = 0.1439 \text{ m}^3/\text{kg}$$

Then the exit velocity is determined from the steady-flow energy balance to be

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} \rightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(2713.4 - 2547.2) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 576.7 \text{ m/s}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{\nu_2} A_2 V_2 = \frac{1}{0.1439 \text{ m}^3/\text{kg}} (16 \times 10^{-4} \text{ m}^2) (576.7 \text{ m/s}) = 6.41 \text{ kg/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial P}{\partial \nu} \right)_s^{1/2} \cong \left( \frac{\Delta P}{\Delta(1/\nu)} \right)_s^{1/2}$$

The specific volume of steam at  $s_2 = 6.0086 \text{ kJ/kg} \cdot \text{K}$  and at pressures just below and just above the specified pressure (1.1 and 1.3 MPa) are determined to be 0.1555 and 0.1340  $\text{m}^3/\text{kg}$ . Substituting,

$$c_2 = \sqrt{\frac{(1300 - 1100) \text{ kPa}}{\left( \frac{1}{0.1340} - \frac{1}{0.1555} \right) \text{ kg/m}^3} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 440.3 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{576.7 \text{ m/s}}{440.3 \text{ m/s}} = 1.310$$

The steam is saturated, and thus the critical pressure which occurs at the throat is taken to be

$$P_t = P^* = 0.576 \times P_{01} = 0.576 \times 3 = 1.728 \text{ MPa}$$

Then at the throat,

$$P_t = 1.728 \text{ MPa} \text{ and } s_t = s_1 = 6.0086 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$h_t = 2611.4 \text{ kJ/kg}$$

$$v_t = 0.1040 \text{ m}^3/\text{kg}$$

Then the throat velocity is determined from the steady-flow energy balance,

$$h_1 + \frac{V_1^2}{2} = h_t + \frac{V_t^2}{2} \rightarrow 0 = h_t - h_1 + \frac{V_t^2}{2}$$

Solving for  $V_t$ ,

$$V_t = \sqrt{2(h_1 - h_t)} = \sqrt{2(2713.4 - 2611.4) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 451.7 \text{ m/s}$$

Thus the throat area is

$$A_t = \frac{\dot{m} v_t}{V_t} = \frac{(6.41 \text{ kg/s})(0.1040 \text{ m}^3/\text{kg})}{(451.7 \text{ m/s})} = 14.75 \times 10^{-4} \text{ m}^2 = \mathbf{14.75 \text{ cm}^2}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus  $h_{10} = h_1$ . At the inlet,

$$h_1 = (h_f + x_1 h_{fg})_{@3 \text{ MPa}} = 1008.3 + 0.95 \times 1794.9 = 2713.4 \text{ kJ/kg}$$

$$s_1 = (s_f + x_1 s_{fg})_{@3 \text{ MPa}} = 2.6454 + 0.95 \times 3.5402 = 6.0086 \text{ kJ/kg} \cdot \text{K}$$

At state 2s,  $P_2 = 1.2 \text{ MPa}$  and  $s_2 = s_{2s} = s_1 = 6.0086 \text{ kJ/kg} \cdot \text{K}$ . Thus,

$$s_{2s} = s_f + x_{2s} s_{fg} \rightarrow 6.0086 = 2.2159 + x_{2s} (4.3058) \rightarrow x_{2s} = 0.8808$$

$$h_{2s} = h_f + x_{2s} h_{fg} = 798.33 + 0.8808 \times 1985.4 = 2547.2 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \rightarrow 0.90 = \frac{2713.4 - h_2}{2713.4 - 2547.2} \rightarrow h_2 = 2563.8 \text{ kJ/kg}$$

Therefore at the exit,  $P_2 = 1.2 \text{ MPa}$  and  $h_2 = 2563.8 \text{ kJ/kg} \cdot \text{K}$ . Thus,

$$h_2 = h_f + x_2 h_{fg} \rightarrow 2563.8 = 798.33 + x_2 (1985.4) \rightarrow x_2 = 0.8892$$

$$s_2 = s_f + x_2 s_{fg} = 2.2159 + 0.8892 \times 4.3058 = 6.0447$$

$$v_2 = v_f + x_2 v_{fg} = 0.001138 + 0.8892 \times (0.16326 - 0.001138) = 0.1453 \text{ kJ/kg}$$

Then the exit velocity is determined from the steady-flow energy balance to be

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} \rightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for  $V_2$ ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(2713.4 - 2563.8) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{547.1 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.1453 \text{ m}^3/\text{kg}} (16 \times 10^{-4} \text{ m}^2) (547.1 \text{ m/s}) = \mathbf{6.02 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left( \frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left( \frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at  $s_2 = 6.0447 \text{ kJ/kg}\cdot\text{K}$  and at pressures just below and just above the specified pressure (1.1 and 1.3 MPa) are determined to be 0.1570 and 0.1353  $\text{m}^3/\text{kg}$ . Substituting,

$$c_2 = \sqrt{\frac{(1300 - 1100) \text{ kPa}}{\left( \frac{1}{0.1353} - \frac{1}{0.1570} \right) \text{ kg/m}^3} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 442.6 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{547.1 \text{ m/s}}{442.6 \text{ m/s}} = \mathbf{1.236}$$

The steam is saturated, and thus the critical pressure which occurs at the throat is taken to be

$$P_t = P^* = 0.576 \times P_{01} = 0.576 \times 3 = 1.728 \text{ MPa}$$

At state 2ts,  $P_{ts} = 1.728 \text{ MPa}$  and  $s_{ts} = s_1 = 6.0086 \text{ kJ/kg}\cdot\text{K}$ . Thus,  $h_{ts} = 2611.4 \text{ kJ/kg}$ .

The actual enthalpy of steam at the throat is

$$\eta_N = \frac{h_{01} - h_t}{h_{01} - h_{ts}} \longrightarrow 0.90 = \frac{2713.4 - h_t}{2713.4 - 2611.4} \longrightarrow h_t = 2621.6 \text{ kJ/kg}$$

Therefore at the throat,  $P_2 = 1.728 \text{ MPa}$  and  $h_t = 2621.6 \text{ kJ/kg}$ . Thus,  $v_t = 0.1046 \text{ m}^3/\text{kg}$ .

Then the throat velocity is determined from the steady-flow energy balance,

$$h_1 + \frac{V_1^2}{2} = h_t + \frac{V_t^2}{2} \rightarrow 0 = h_t - h_1 + \frac{V_t^2}{2}$$

Solving for  $V_t$ ,

$$V_t = \sqrt{2(h_1 - h_t)} = \sqrt{2(2713.4 - 2621.6) \text{ kJ/kg} \left( \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 428.5 \text{ m/s}$$

Thus the throat area is

$$A_t = \frac{\dot{m} v_t}{V_t} = \frac{(6.02 \text{ kg/s})(0.1046 \text{ m}^3/\text{kg})}{(428.5 \text{ m/s})} = 14.70 \times 10^{-4} \text{ m}^2 = \mathbf{14.70 \text{ cm}^2}$$

## Fundamentals of Engineering (FE) Exam Problems

**17-154** An aircraft is cruising in still air at 5°C at a velocity of 400 m/s. The air temperature at the nose of the aircraft where stagnation occurs is

- (a) 5°C                      (b) 25°C                      (c) 55°C                      (d) 80°C                      (e) 85°C

Answer (e) 85°C

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.4

P1=66 "kPa"
Vel1=230 "m/s"
VS1=SQRT(k*R*T1*1000)
Mach=Vel1/VS1
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Mach=Vel1/VS2; VS2=SQRT(k*R*(T1-273)*1000) "Using C for temperature"
W2_Mach=VS1/Vel1 "Using Mach number relation backwards"
W3_Mach=Vel1/VS3; VS3=k*R*T1 "Using wrong relation"
```

**17-158** Consider a converging nozzle with a low velocity at the inlet and sonic velocity at the exit plane. Now the nozzle exit diameter is reduced by half while the nozzle inlet temperature and pressure are maintained the same. The nozzle exit velocity will

- (a) remain the same.      (b) double.      (c) quadruple.      (d) go down by half.  
 (e) go down to one-fourth.

*Answer* (a) remain the same.

**17-159** Air is approaching a converging-diverging nozzle with a low velocity at 20°C and 300 kPa, and it leaves the nozzle at a supersonic velocity. The velocity of air at the throat of the nozzle is

- (a) 290 m/s      (b) 98 m/s      (c) 313 m/s      (d) 343 m/s      (e) 412 m/s

*Answer* (c) 313 m/s

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```

W3_Vthroat=k*R*T_throat "Using wrong relation"

```

**17-162** Consider gas flow through a converging-diverging nozzle. Of the five statements below, select the one that is incorrect:

- (a) The fluid velocity at the throat can never exceed the speed of sound.  
 (b) If the fluid velocity at the throat is below the speed of sound, the diversion section will act like a diffuser.  
 (c) If the fluid enters the diverging section with a Mach number greater than one, the flow at the nozzle exit will be supersonic.  
 (d) There will be no flow through the nozzle if the back pressure equals the stagnation pressure.  
 (e) The fluid velocity decreases, the entropy increases, and stagnation enthalpy remains constant during flow through a normal shock.

*Answer* (c) If the fluid enters the diverging section with a Mach number greater than one, the flow at the nozzle exit will be supersonic.

**17-163** Combustion gases with  $k = 1.33$  enter a converging nozzle at stagnation temperature and pressure of  $400^\circ\text{C}$  and  $800\text{ kPa}$ , and are discharged into the atmospheric air at  $20^\circ\text{C}$  and  $100\text{ kPa}$ . The lowest pressure that will occur within the nozzle is

- (a)  $26\text{ kPa}$                       (b)  $100\text{ kPa}$                       (c)  $321\text{ kPa}$                       (d)  $432\text{ kPa}$                       (e)  $272\text{ kPa}$

Answer (d)  $432\text{ kPa}$

**Solution** Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.33
Po=800 "kPa"
"The critical pressure is"
P_throat=Po*(2/(k+1))^(k/(k-1))
"The lowest pressure that will occur in the nozzle is the higher of the critical or atmospheric pressure."

"Some Wrong Solutions with Common Mistakes:"
W2_Pthroat=Po*(1/(k+1))^(k/(k-1)) "Using wrong relation"
W3_Pthroat=100 "Assuming atmospheric pressure"
```
